Bestimmungstabellen der Gallen

(Zoo- und Phytocecidien) an Pflanzen Mittel- und Nordeuropas

2 Bände. Von Dr. HERBERT BUHR, Mühlhausen (Thür.). Mit einem Geleitwort von Prof. Dr. Erich Martin Hering, Berlin. Mit 443 Figuren auf 25 Tafeln. Format 16·7 × 24 cm.

Band 1: Pflanzengattungen A–M; Gallennummern 1–4388. XVI, 761 Seiten. 1964. Leinen 81.60 DM.

Band 2: Pflanzengattungen N–Z; Gallennummern 4389–7666. Etwa 620 Seiten. Leinen etwa 80,— DM. Erscheint 1965.

Das zweibändige Werk stellt in seiner umfassenden und gründlichen Behandlung sämtlicher an Pflanzen zu beobachtender Gallenbildungen eine einmalige wissenschaftliche Leistung dar. Auf Grund jahrzehntelanger Studien war es dem Verfasser möglich, die Bestimmungsschlüssel so aufzubauen, dass praktisch jede Gallenbildung, sei sie nun durch tierische oder pflanzliche Parasiten erzeugt, an ihrer Wirtspflanze identifiziert werden kann. Damit ist eine Bestimmung aller Gallen auch dem weniger geübten Praktiker oder sonstigen Interessenten gut möglich.

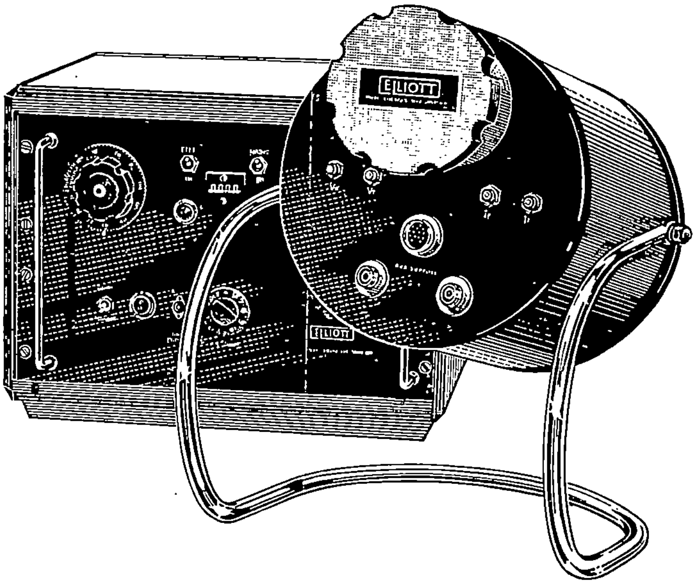
ELLIOTT

NEUTRON GENERATORS



FOR EDUCATION RESEARCH AND ACTIVATION ANALYSIS

Pulsed 10^9 neutrons per second generator is easily transportable, requires no special shielding, may be operated in a laboratory or lecture theatre, is ideal for demonstrating most neutron reactions and the principles of activation analysis.

Elliott L type generator for continuous output of 10^{10} neutrons per second, fitted with long life sealed off source tube. No vacuum pumps or target replacements; constant output of neutrons; small, compact tube minimises shielding costs. Complete equipment with pneumatic sample transfer system available for activation analysis. *For full details write or telephone:*

fluctuating image now lies on the transparent negative. The image is now almost entirely cancelled by its negative. It is, however, most completely cancelled when the image most nearly corresponds to the negative. As the image is displaced, by the atmospheric or other disturbances, there is an increase in intensity. This is detected by a single photoelectric cell which covers the entire image plane, and so receives plenty of light. We can thus detect the presence of any shift of the image—though not the direction of shift—from increase in the output of the cell. The output rises with any discrepancy of the image from the statistically correct 'master' negative—not only shifts but also loss of focus and the 'milkiness' produced by regions of different refractive index smaller than the aperture of the instrument. (This last point I have established by means of a ripple tank.)

Having attained a signal indicating disturbance from the statistically correct image, it is a simple matter to use the signal to produce a second photograph free of disturbance. This may be done by using a second camera which shares the image with the first, by means of a beam splitter. This second camera is fitted with an electrically operated shutter which opens only when the output from the photo-cell is near its minimum value, corresponding to a close fit of the fluctuating image with the master negative.

In this way we separate informational integration from the integration of energy needed to expose the final picture, which is built up from many short exposures occurring whenever the image is close to the 'master'.

The preliminary experiments are limited to simulation of atmospheric disturbance, by placing an oscillating 'Perspex' sheet between the object and the optical system, and a ripple tank.

The beam splitter is a half-silvered mirror placed at 45°, so that the second camera (an 'Exacta' 35-mm single-lens reflex) is provided with the same image as the large camera carrying the master negative and the photo-cell. The second camera is fitted with a specially made shutter, consisting of a pair of electromagnetic vibrator units (Advance type VI) which drive a pair of metal vanes shaped to form a square opening, increasing in size as the vanes are withdrawn by the opposed vibrator units. The circuit consists of an oscillator (400 c/s) allowing a.c. amplification from a bridge which is unbalanced by the photo-cell changing in resistance with increasing light, when the image loses register with the master. The amplified output is rectified, and used to energize the vibrator units to close the shutter.

An example of how a shifting image is improved is shown in Figs. 1*a* and *b*. Fig. 1*a* was obtained from a long exposure of the Moon model while the 'Perspex' plate was oscillating about a vertical axis, to produce horizontal disturbance. The degeneration along the horizontal axis is very apparent. Fig. 1*b* shows the improvement obtained—the optical conditions being identical—when the shutter system is switched on. Some degeneration on the horizontal axis can still be seen: this may be further reduced by increasing the gain of the amplifier.

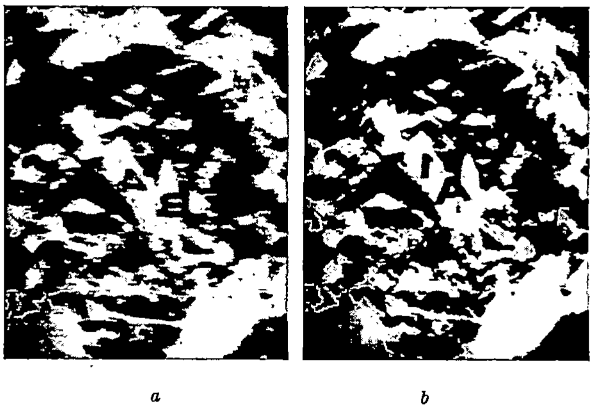

Fig. 1. *a*, Photograph of Moon model taken by the second camera through horizontal disturbance produced by oscillation of a 'Perspex' plate (1 in. thickness: rotated through 20°). This is the same degree of blurring as in the 'master' negative which gives Fig. 1*b*. *b*, The same Moon model, also taken by the second camera, but only when the electrically operated shutter is open for periods when the disturbed image nearly corresponded with the blurred 'master' negative. The difference gives an idea of the improvement to be expected for simple shift of images with high magnification telescopes. (Relative shift can be produced with a ripple tank, and this also gives signals which should produce improved photographs)

The improvement shown is given by a shutter open/closed ratio of about 6 : 1. This may be increased by increasing the gain in the present arrangement, or by introducing a gate, working the shutter as an all-or-none device. It is important to note that the improvement is from a blurred master negative identical with Fig. 1*a* since it was taken through the disturbance.

We are now simulating atmospheric disturbance with a layer of water agitated by an electromagnetic vibrator, driven from a low-frequency noise source. The resulting disturbances appear very similar to those experienced with an astronomical telescope. It remains to discover the efficiency of the technique under these more realistic conditions. It might then be directed to the Moon and the planets.

I thank Mr. Stephen Salter and Mr. William Matthews for their help in setting up the preliminary experiments. I also acknowledge receipt of grant *Af-EOARDC* 63–93 monitored by the European Office, Office of Aerospace Research, for work on visual perception.

AGE OF CALEDONIAN OROGENY AND METAMORPHISM IN BRITAIN

By F. J. FITCH
Department of Geology, Birkbeck College, University of London
DR. J. A. MILLER
Department of Geodesy and Geophysics, University of Cambridge
AND
DR. P. E. BROWN
Department of Geology, University of Sheffield

As part of a continuing programme of research into the chronology of British Caledonian rocks, we have recently completed a critical review and reappraisal of the geological evidence and isotopic age data from Britain. Excellent summaries of the geological evidence, with very full bibliographies, can be found in *The British Caledonides*[1], also in Read[2], McKerrow[3], and Watson[4]. Published isotopic data are available in refs. 5–20. From

Table 1. New Potassium–Argon Age Determinations

Sample	Ref. and method	K_2O (%)	Atmo. contam. (%)	Vol. radiogenic ^{40}Ar (mm^{3}NTP) / wt. sample (g)	Apparent age and error (m.y.)
Epidiorite, Co. Mayo. Basic intrusion into Wenlock Beds: metamorphosed during Caledonian orogeny	612 K/Ar whole rock	1·77 ± 0·03	2·1	0·02737	417 ± 11 (that is, apparent age of Caledonian metamorphism)
Cataclastic chlorite-muscovite schist, Porth Trecastel, Anglesey. (*MR SH* 333707.) Gwna Beds (Pre-Cambrian) metamorphosed in Monian orogeny. Age discrepantly low as a result of Caledonian cataclasis	*FM* 125 467 K/Ar muscovite	3·06 ± 0·01	7·3	0·07300	611 ± 16 (that is, a minimum age for the Monian orogeny)
'Caledonian' chlorite, separated from sheared migmatic soda-granite, the Gader Inlier, Mona Complex, Anglesey. (*MR SH* 293923)	*FM* 199 591 K/Ar chlorite	1·52 ± 0·038	1·6	0·02304	410 ± 16 (that is, apparent age of Caledonian orogeny)

$\lambda_\beta = 4{\cdot}72 \times 10^{-10}$ yr^{-1}. $\lambda_e = 0{\cdot}584 \times 10^{-10}$ yr^{-1}.

the considerable volume of unpublished isotopic results at hand, certain relevant new age determinations are quoted here (Table 1).

The geochronological work of Giletti *et al.*[7] in 1961 suggested that the age of metamorphism of the Dalradian rocks of Scotland and Ireland was significantly different at 475 ± 15 m.y. from that of the last metamorphism to affect the Moine Series at 415 ± 15 m.y. This tentative conclusion, although derived from very scanty data, has become an unquestioned dogma, and the idea of a difference in age of metamorphism between the Moine and Dalradian rocks has persisted in both geological and geochronological thought. As a result of our reappraisal of the evidence, we have come to the conclusion that this supposed difference does not exist. We are convinced that the age patterns obtained from both the Moine and Dalradian rocks can best be explained as resulting from a combination of partial and complete 'overprinting' of older metamorphic rocks by a (420–410) ± 10 m.y. main Caledonian orogenic/magmatic/metamorphic event which was contemporaneous throughout Britain. Full discussion is reserved for future publication; but it was thought that this important re-interpretation should be communicated now.

Only in especially favourable circumstances can isotopic age determinations reveal the true or 'initial' age of crystallization of a rock. The various causes of discrepancy have been discussed fully in Fitch and Miller[18], Miller and Fitch[20] and in the discussion to Lambert[21]. Briefly, we do not accept the view that metamorphic complexes or igneous intrusions can, in general, remain above some 'threshold' temperature for daughter element retention over extremely long periods amounting to tens of millions of years. In the discussions already quoted here, we provide evidence which suggests that the cooling period is normally far less than that involved in the experimental error of an age determination, and is, therefore, not a factor of geological significance in this context. We do believe, however, that the principal cause of discrepancy in rocks of suitable retentive mineralogy and fabric is 'overprinting' by later geological events. Partial and complete overprinting of older rocks leads to recognizable patterns of age results from which it is possible to select the geologically significant dates. It must be emphasized here that to take an average of a series of partially overprinted ages leads to a completely meaningless figure. It is the statistical pattern of ages which is important. Results from Morar[7,12,16] and from the Glen Dessary Syenite[17] leave no doubts regarding the Moine Series. They are a late Pre-Cambrian sedimentary group (deposited after 1,600 m.y., most probably between 1,200 and 800 m.y.) involved in Pre-Cambrian metamorphism and magmatism (> 720–765 m.y.) and overprinted by the Caledonian event around 420–410 m.y. Unquestionable evidence of the Pre-Cambrian event can only be found in the western part of Inverness-shire and southern Ross; elsewhere the ages obtained from the Moines are almost entirely overprinted to become Caledonian. A pattern of ages is obtained which falls rapidly from rare Pre-Cambrian ages to a very prominent maximum between 435 and 405 m.y., with its peak between 420 and 410 m.y., then falls off again to a few scattered lower ages.

Taking into consideration the smaller sample available, the age pattern of Caledonian overprinting obtained from the Dalradians is identical to that obtained from the Moines. This conclusion was reinforced by an examination of the age patterns of Argyll and Perthshire in which ages from the Central Highlands granulites and Dalradian rocks were considered together. Unequivocal evidence of a Pre-Cambrian age of early metamorphism for the Dalradians is lacking, however, unless it be present at Ben Vuroch. The only certainty to be found in the Dalradian pattern is that the 420–410 m.y. Caledonian metamorphism is overprinted on rocks first metamorphosed at some earlier date, for no date above 470 m.y. has yet been obtained in the Cambridge laboratory from a Dalradian meta-sedimentary rock. The older whole-rock rubidium–strontium ages of Giletti *et al.*[7] from Ben Vuroch (590 ± 130 m.y. and 670 ± 160 m.y.) and from the intimately associated Central Highlands granulites of Perthshire (565 ± 160 m.y.) are suggestive of a similar Pre-Cambrian age for the early metamorphism of both the Moine and Dalradian rocks, but are not in themselves conclusive.

In 1961, a 475-m.y. first metamorphism of the Dalradian rocks was acceptable because it agreed with current geological hypothesis. Kennedy[22] in 1955 put forward a strong case for mid-Ordovician orogeny in the Scottish Highlands, and the earlier discovery of mid-Cambrian trilobites in the Highland Border Series by Pringle[23] was regarded as suggesting that much of the Dalradian succession was Cambrian in age. The complete absence of evidence suggesting 475 m.y. metamorphism in the Moine areas of the Highlands remained, however, an inexplicable puzzle. New geological evidence from Ireland (see, for example, refs. 24–28) has made it quite clear that the Connemara Dalradian was folded and first metamorphosed previous to the Arenig, and acted as a tectonically distinct basement during the Caledonian folding and metamorphism of the Ordovician and Silurian rocks of Murrisk. The available isotopic data from north-west Ireland are summarized in Table 2. It will be seen that there is clear evidence of the 'overprinting' of an earlier metamorphic complex by the Caledonian event at 420–410 m.y. (as defined by the age of 417 ± 11 m.y. obtained from a schistose epidiorite intrusive into Wenlock strata (Tables 1 and 2)). The overprinted metamorphic event can be defined as having occurred some time before 490 ± 20 m.y. (the oldest age quoted in Table 2).

It may be concluded with some confidence that the earlier Dalradian orogeny and metamorphism of Britain was pre-Arenig. On the 1959 time-scale of Holmes[29] this would be at least 500 ± 15 m.y. There is no reason at present to supppose Holmes's estimate to be drastically wrong[18]. If the mid-Cambrian rocks of the Highland

Table 2. PERTINENT AGE RESULTS FROM IRELAND

Apparent age + error (m.y.)	Method and mineral used	Details of rock	Ref.

485 ± 22	Rb/Sr muscovite	Re-run of above by	12
490 ± 20	Rb/Sr muscovite	Connemara schist, Clifden, Co. Galway	7

Border Series are truly part of a continuous Dalradian succession, then this orogenic episode must have been late-Cambrian or earliest Ordovician in age. There are many difficulties inherent in the acceptance of this correlation, for nowhere in the British Isles can definite isotopic or geological evidence be found which indicates major orogeny at this time. Studies of ancient rocks throughout Britain have so far failed to reveal any significant concentrations of partially or completely overprinted ages that might be referred to such an event. Neither will structural or stratigraphical considerations support such a conclusion. Evidence of post-Tremadocian/pre-Arenig parorogeny (the terms evorogeny and parorogeny are used here as defined by Simpson[30]) and unconformity is clear in North Wales[31]; but before this minor disturbance, Tremadocian sedimentation in Wales was a record of relatively quiescent conditions. The Upper Cambrian/Earliest Ordovician sedimentation of Skye and the north-west Highlands again suggests regional quiescence. Throughout Britain there is evidence of important Arenig transgressions, but we maintain that the time interval and style of this transgression (for example, as indicated by the analysis of the Arenig rocks of Murrisk by Dewey[26]) are not compatible with it representing the major (F_1/F_2) polyphase orogenic–metamorphic event of the Grampian Highlands. That such an event, accompanied by recumbent folding on the grand scale, could have been closely restricted to the Dalradian belt and have left the rest of Britain virtually unaffected is to us unacceptable. Recent structural investigations in the Caledonian belt south of the Highlands[28,32–37] clearly demonstrate the presence of a single unified Caledonian evorogenic structural complex involving Arvonian, Cambrian, Ordovician and Silurian rocks up to and including Ludlovian. In Anglesey the metamorphic basement of this evorogeny is the Pre-Cambrian Mona Complex (orogenic metamorphism > 611 ± 16 m.y. (see Table 1)); in Ireland and Scotland it is the Dalradian and Moine. We believe that the Mona Complex should be equated with the Dalradian, for there is a general similarity between the Upper Dalradian succession and that of the Mona Complex and they occur in similar structural environments. If this correlation is true, then the evidence from the Highland Border requires re-interpretation. Read[2] suggested that the fossiliferous Cambrian limestones might be tectonic intercalations within the Dalradian. Alternatively it might be suggested that Lower Palæozoic outliers have been folded in with Dalradian basement rocks during the Caledonian evorogeny, and that Caledonian polyphase evorogenic structures are overprinted on earlier Pre-Cambrian polyphase recumbent structures along the Highland border.

In the working hypothesis at present favoured by us, two post-Lewisian orogenic systems are believed to cross Caledonian Britain. The earlier (possibly contemporaneous with the Carolinides of east Greenland, the Gardar Cycle of south Greenland and the Dalslandian of Sweden) culminated in a pre-(720–765) m.y. evorogeny which involved Moine, Dalradian and Monian rocks. On a basement consisting of the regional metamorphic rocks, migmatites and intrusives of this orogeny was deposited the Eo-Cambrian and Lower Palæozoic rocks of the Caledonian geosyncline. Over much of Northern Britain these deposits were thin, and both Eo-Cambrian and Cambrian strata are largely absent. Parorogenic disturbances of increasing intensity can be distinguished in various parts of this mobile belt, but the main evorogenic event that involved the whole Caledonian system did not begin until late in the Silurian. Paralic and terrestrial conditions appeared in western Ireland and in the Midland Valley of Scotland in the Upper Silurian (most probably in the Ludlovian, in rocks often erroneously referred to as 'Downtonian', but see the opinion of Westoll in the discussion on Rolfe[38]). Elsewhere Ludlovian troughs, slump beds and turbidites indicate crustal instability. Throughout the Caledonian mobile belt the evorogenic structures involve all strata older than Downtonian, including the high Ludlovian of the English Lake District and of South Wales. In many areas the Downtonian is missing, but where it is present, it rests unconformably on the older rocks (for example, at Stonehaven and on the south-east flank of the Towy anticline in South Wales). The Downtonian is followed conformably by the Lower O.R.S., and where it is absent, it is the Lower O.R.S. which is seen to be unconformable on the older Pre-Cambrian and Lower Palæozoic rocks of the mobile belt. In the Grampians the Lower O.R.S. is unconformable on Dalradian, in the Midland Valley it rests with strong unconformity on Ordovician and Silurian rocks. Angular discordance is absent at Lesmahagow, but in a regional synthesis George[39] finds evidence for major pre-Devonian orogeny with fold amplitudes of 10,000–15,000 ft. in the Midland Valley area. In the Southern Uplands the stratigraphical break is between Wenlock/?Ludlow and the Lower O.R.S.[37,40]. The Mell Fell conglomerate of the Lake District is rich in Ludlovian pebbles, and is regarded by Capewell[41] as being a Lower O.R.S. mountain piedmont deposit. In North Wales the earliest post-orogenic deposits are the presumed Lower O.R.S. rocks of Anglesey which accumulated in an intermontane basin unconformably on folded Ordovician and Silurian and were themselves folded and cleaved in what can only have been a mid-Devonian parorogeny. In Ireland a similar position is occupied by the unfossiferous Dingle Beds.

Only in the Welsh Borderland, outside the limits of the Caledonian mobile belt proper, was Ludlovian and Downtonian sedimentation undoubtedly continuous. Here Allen and Tarlo[42] refer to two extensive bone beds as indicators of major uplift in the adjacent geosyncline, suggesting its final transformation into a land area. The first of these bone beds occurs at the level of the top of the Aymestry Limestone. The disappearance of the graptolitic facies at this level and the presence of a major stratigraphical break with submarine gullying in the Leintwardine area[43] add support to the view that this bone bed represents the initiation of the culminating phase of the Caledonian evorogeny. The second bone bed is the well-known 'Ludlow Bone Bed' on the boundary between the Ludlovian and the Downtonian, after which deltaic, near shore and finally arid continental conditions rapidly ensued in the Welsh Borders and farther south.

Late Caledonian parorogeny is known to have been important after the deposition of the Lower O.R.S. in many parts of Britain. Middle and Upper O.R.S. can be seen in various places to be unconformable on Lower

O.R.S. and older rocks. Nevertheless, we believe that the major Caledonian structures in the Pre-Downtonian rocks of Britain reveal an overall tectonic unity that is distinct from the structural pattern seen within the Lower O.R.S. and Downtonian, and that the weight of isotopic and stratigraphic evidence suggests that these structures were produced in an evorogenic event that occurred in uppermost Ludlovian/earliest Downtonian times between (420 and 410) ± 10 m.y.

In Scotland it is suggested that the 420 m.y. ages are to be equated with the third phase (F_3) structures and metamorphism of the Highlands, the effects of which are superimposed and 'overprinted' on rocks folded and metamorphosed in earlier phases (bracketed letters refer to the terminology used in *The British Caledonides*[1]). The (F_3) movement phase of the Highlands is accompanied by retrogressive metamorphism in parts of central Perthshire, but elsewhere it is closely associated with the development of migmatites and with the magmatism responsible for early 'forceful' Caledonian granite bodies dated by Miller and Brown[16] as having been intruded around 420 ± 15 m.y. Evidence which suggests that the same episode of crustal stress was responsible for the major Caledonian folds (F_1 in the terminology of Helm, Roberts and Simpson[34]) of the Irish Sea area can be obtained in North Wales and Ireland. The post F_1 basic magmatism of North Wales has been given a minimum date of 411 ± 14 m.y. (ref. 19), and the grouping of five overprinted ages from Ireland between 424 and 414 m.y. suggests that the main Caledonian movements and metamorphism in both areas were around 420–410 m.y. Secondary chlorite produced by Caledonian dynamic metamorphism in the Pre-Cambrian granite-gneiss of the Gader Inlier on Anglesey revealed an age of 410 ± 16 m.y. (Table 1), thus defining a minimum age for the cessation of major Caledonoid dynamic deformation in the area (which includes both F_1 and F_2 in the terminology of Helm *et al.*[34]).

Thus it would appear that the F_1 episode of Britain south of the Highlands is to be broadly correlated with (F_3) of the Highlands, and that this event was the main Caledonian evorogeny of Britain, beginning in the Upper Ludlovian around 420 m.y. and continuing into the earliest Downtonian around 410 m.y. Major post-tectonic Lower O.R.S. volcanism and intrusive acid magmatism occurred in Scotland and elsewhere around 405 m.y., and a further episode of major granite intrusion is known around 395 m.y., still within the Lower O.R.S. From a consideration of the varying sedimentary pattern over Britain, it would appear that the growth and subsequent uplift of the major Caledonian structures in the geosynclinal belt south of the Highlands, although beginning in the Upper Ludlow, did not finally exclude the sea from all areas until Lower O.R.S. times, when continental conditions became general and Caledonian post-tectonic granite magmatism was at its height.

TECTONO-MAGMATIC EVOLUTION OF THE SVECOFENNID CHELOGENIC CYCLE IN SOUTH GREENLAND

By D. BRIDGWATER and B. J. WALTON
Geological Survey of Greenland, Copenhagen K

RECENT compilation of isotopic age determinations from South Greenland[1], together with work on a newly discovered appinitic suite and the recognition of its orogenic significance[2], have led to the suggestion that the geology of South Greenland may best be understood in terms of a developing chelogen[3]. The information contained in this article is based on work of the Geological Survey of Greenland. The ideas expressed are our own and will be tested by relevant isotopic age determinations as they become available. A programme to provide these determinations has been started recently at the Mineralogical Museum, Copenhagen. In view of the renewed interest in continental drift and the key position of South Greenland in relation to Europe and America it seems worth while presenting an interpretation based on the detailed geological knowledge of the area combined with the few known age determinations.

As recognized by Wegmann[4] the rocks of South Greenland fall into three main groups: (*a*) an older gneissose basement preserved as cores to major structures and as conglomerate pebbles (the pre-Ketilidian); (*b*) a Ketilidian series of metasediments and metavolcanics lying unconformably on the pre-Ketilidian basement, together with gneisses and igneous rocks; (*c*) the Gardar—a younger

series of unmetamorphosed sediments (dominantly arkoses) and lavas with an alkaline to per-alkaline suite of igneous rocks.

The pre-Ketilidian basement which possibly forms a major part of the west coast of Greenland has not been recognized as mappable units south of Kobberminebugten (Fig. 1). Its only interest in this article is to note that some confusion over the term Ketilidian exists. This is due to the use of the term in the Ivigtut region for a series of reactivated gneisses and granites[5] some of which are now known to be below the Ketilidian basal conglomerate[6]. Age determinations of between 3,000 m.y. and 2,300 m.y. come from areas in which the rocks could be reasonably interpreted as being pre-Ketilidian.

The Ketilidian geosynclinal rocks preserved in the Ivigtut region show the following succession: basal conglomerate, quartzites, dolomites, pelites, greywackes, pillow lavas, pyroclastics and basic flows and sills. A second well-preserved area of supracrustal rocks exists around Tasermiut fjord where the upward (probably stratigraphical) succession is: pelitic schists, quartzites, and basic metavolcanics[7]. The main Ketilidian metamorphism varies from epidote-amphibolite facies in the north to granulite facies in the south. Three main episodes of folding occurred of which the dominant gave north-east trending axes. Syn- and late-tectonic granitization formed mainly oligoclase bearing gneisses. Further introduction of felsic material probably associated with re-mobilization of considerable amounts of pre-Ketilidian gneisses formed the Julianehåb granite, a variable mass covering at least 8,000 square kilometres between Kobnerminebugten and Julianehåb[8]. Relict structures within the granite generally correspond to the dominant north-east fold direction. The foliated granite and gneisses contain thin concordant or slightly discordant, foliated, folded and granitized basic sills and dykes which probably represent relics of the feeders to geosynclinal basalt activity[7,9]. More discordant to the granite are a younger series of basic and intermediate dykes (second period dykes). These were probably emplaced mainly as dolerites into cold rocks[9,10], but were later metamorphosed and granitized. The return to plutonic conditions which this indicates, called the Sanerutian and dated between 1,650 and 1,500 m.y., has previously been considered as a thermal event essentially independent of the main phase of granitization described here, and has been regarded as a marginal effect of the Nagssugtoquidian fold belt[11,12]. This supposition was based mainly on the correlation of the main phase of Ketilidian granitization with the gneisses dated from Godthåb at 2,700 m.y.[13]. However, the recognition of pre-Ketilidian basement north-east of Ivigtut reduces the likelihood of the correlation. It now seems possible that the main phase of Ketilidian plutonism may correspond to the widespread thermal activity in the Canadian shield at about 1,800 m.y. although no proved rocks of this episode in South Greenland have been dated. If it is true that the Ketilidian and Sanerutian plutonic episodes are closely spaced in time, the chronological significance of the period of basic dyking separating them is considerably reduced; this may only represent a temporary volcanic phase in the development of a single orogeny.

A factor which supports the idea that the two plutonic episodes belong to the same orogeny is the recognition of an appinitic suite of rocks intruded immediately following the second period basic dykes. These rocks vary from alkali-noritic gabbros to hypersthene–augite or hornblende bearing diorites and hypersthene monzonites. The most thoroughly investigated group of these rocks occurs north of Narssarssuaq[2]. In this area there is a close connexion between the intrusion of the large basic and intermediate masses and the formation of younger granite by reactivation of older granite and gneiss. Relict second period basic dykes are commonly present within the younger granite although parts of the granite show signs of having been mobile, for example, they contain a closely mixed assortment of angular xenoliths.

Elsewhere in South Greenland the granites formed in conjunction with comparable basic rocks are essentially allochthonous and not formed directly from the surrounding gneisses[14]. Other areas of reactivation of earlier rocks are widespread in the Julianehåb granite without recognizable connexion to the intrusion of basic masses. The reactivation is best recognized by its effect on the second period basic dykes although it can be suggested in areas where the granite has recrystallized after a period of shearing in non-plutonic conditions. Outside the main area of Julianehåb granite younger granites are commonly associated with belts of renewed movement parallel to the main Ketilidian structural trend[9].

An intrusive phase of microdiorite sheets occurred contemporaneously with the major diorite masses. Outside the main zone of granite reactivation there are also occasional closely spaced swarms of intermediate dykes. These may represent feeders to orogenic andesitic lavas which have been completely removed by erosion. Other minor basic and intermediate intrusions were emplaced after the peak of reactivation but before the end of plutonic conditions. Three main types have been recognized: dykes intruded into hot shear zones while movement was still taking place[9], dykes intruded into mobile granite[14] and sills and sheets the intrusion of which was closely followed by aplitic granite forming 'net-veined diorites'[15]. Some of the late microdiorite sheets grade into hornblende lamprophyres with interstitial calcite and locally minor phases approaching carbonatites are developed.

The appinitic intrusive complexes north of Narssarssuaq show many similarities to the type occurrences in Scotland. They also have a closely comparable position in the orogenic chronology[16,17], that is, they were intruded after the main periods of folding, metamorphism and granitization but just before the formation of the younger granites. Sutton[18] considers that in Scotland there is just one orogenic cycle represented (that is, Caledonian) and similarly in South Greenland the events from the Ketilidian sedimentation to the end of the second phase of plutonism could be regarded as one complete orogenic cycle. These appinitic rocks appear to form normal members of an orogenic calc-alkaline suite. They also show a sub-alkali development which corresponds to Vorobieva's[19] folded-structure association of alkali rock petrogenesis. In particular, large masses of hypersthene monzonite and locally syenite appear to have formed by diffusive potassium enrichment of the central parts of a basic-intermediate magma chamber consequent on the earlier crystallization of the margins and roof of the chamber. Examples of bodies believed to have been formed by similar processes have been described by Boone[20] and Vance[21]. The tectonic setting of these rocks can perhaps be explained by considering the possible later stages in the development of a root-zone of an orogenic belt. After the main compressional period of folding, metamorphism and granitization, down-dragging convection currents beneath the belt died down and eventually ceased. The orogenic pile cooled and started to rise up due to isostasy. Partial tensional conditions now allowed the introduction of simatic material (presumably tholeiitic) represented in South Greenland by the second period basic dykes. Because of the orogenic environment this basic magma became extensively contaminated by sialic material with the consequent formation of a high proportion of intermediate igneous rocks. Rising palingenetic acid magmas possibly supplemented with newly differentiated acid material would tend to follow the more basic intrusions. Abundant wrench faulting and locally the development of foliation and folding could be expected to accompany this phase.

If this interpretation is correct the Sanerutian events could be the logical epeirogenic uplift phase of the orogeny which started during Ketilidian time rather than the expression of a separate orogenic development as has been suggested previously. It should be noted, however, that it is perfectly possible that a younger orogeny was developing at this time further away on the flanks of the original orogenic belt. It is also possible that a minor orogenic belt comparable to the Labrador Trough[22] was superimposed on the epeirogenic uplift phase of the Ketilidian–Sanerutian orogeny.

Gardar sedimentation of mainly coarse arkosic sandstones and volcanism, the main phase of which started as fracture-controlled agglomerate vents followed by basic lavas with alkali tendencies[23], began in basins controlled by major east-south-east wrench faults[24]. These faults were probably initiated during the Sanerutian plutonic phase[25] and remained active at least under the initial stage of Gardar sedimentation. From comparisons with the post-orogenic sediments in other areas, for example, the Caledonides[17] and the Appalachians[26] it seems probable that these sediments were deposited soon after the end of plutonism and may have overlapped the formation of the younger granites elsewhere.

The Gardar now preserved in South Greenland consists dominantly of intrusive igneous rocks. This activity can be divided somewhat arbitrarily into three phases[27]: (*a*) Early Gardar in which nepheline syenites, carbonatites, lamprophyres and trachytes predominate[28]. (*b*) Mid-Gardar characterized by several generations of olivine dolerites, trachydolerites, microsyenites, larvikitic dykes and giant composite gabbro–syenite dykes. Many of the dykes contain large masses of anorthosite and labradoritic feldspar[29]. Tensional conditions leading to the formation of dykes trending north-east were dominant in the mid-Gardar. (*c*) Late-Gardar characterized by major alkaline complexes including Nunarssuit[30], Kûngnât[31] and Ilímaussaq[32]. The tectonic control of the late-Gardar appears to have changed from that of the mid-Gardar; instead of the dominant north-east trending fissures the late-Gardar complexes are approximately equidimensional and emplaced by stoping. Reliable age determinations are limited to late-Gardar rocks which range from the Ivigtut Granite at 1,255 m.y.[33] to the agpaitic rocks of Illímaussaq at 1,020 m.y.[34] (modified from Moorbath *et al.*). The Gardar igneous activity must therefore have lasted at least 250 m.y. and possibly lasted 300–400 m.y. Whether there is a major break between any of the phases is not known.

The early-Gardar alkali magmatism occurs in a similar setting to the igneous activity of the Midland Valley of Scotland, the Oslo province, and the White Mountain magma series of New Hampshire[17]. All are associated with fault zones which probably developed during the final epeirogenic uplift at the end of an orogeny. They agree with the general setting described by Vorobieva[19] for alkali magmatism of platform type in the U.S.S.R. She remarks that alkali magmatism occurs in unstable conditions in the late or last stages of a tectono-magmatic cycle. Yoder and Tilley[35] suggest that the initiation of an alkali basalt trend takes place at a greater pressure than a tholeiitic trend. They equate the difference in magma type to a difference in depth of formation.

Mid- and late-Gardar intrusions were emplaced between 250 and 500 m.y. after the end of plutonism in South Greenland. Similar alkali rocks were formed at a comparable time in the Canadian[36] and Scandinavian[37] shields immediately before the widespread orogenic activity which marked the beginning of the Grenville chelogenic cycle. At the present time, at the presumed end of the Grenville chelogenic cycle[8] alkali rocks are being formed along deep fracture zones, for example, the African rift valley, and have been formed in the Tertiary volcanism of Greenland and Scotland.

Sutton[3] suggested that with the development of a chelogenic cycle orogenies are progressively restricted to the margins of the continental masses probably consequent on the fusion of subcontinental convection cells. The same process results in disruption of the continental masses. This disruption might be expected to be the cause of exceptionally deeply penetrating tensional zones which in turn may result in alkali magmatism. From the global point of view, as Sutton has noted, continental disruption produces dominantly basaltic magmatism, but it seems likely that this leads to alkali rocks genesis in areas where post-orogenic fissures were developed to great depths.

Geological evidence suggests that the Sanerutian plutonic episode may represent the epeirogenic uplift phase of the orogeny which started in Ketilidian time. If the main Ketilidian metamorphism proves to have a date of about 1,800 m.y. this orogeny would then be an early event in the Svecofennid chelogenic cycle. The Gardar alkaline activity may be due to continental disruption during the later phases of the chelogenic cycle. The whole sequence of events forms a characteristic tectono-magmatic cycle[17,38]. The location of the Gardar alkali activity may be due to a fundamental weakness in the crust developed during the epeirogenic uplift phase of the Ketilidian–Sanerutian orogeny which continued to control magmatism marginal to the early phases of the Grenville orogenic belt, which probably passed just south of what is now Greenland.

A METHOD FOR DESCRIBING THE PACKING TEXTURE OF CLASTIC SEDIMENTS

By I. J. SMALLEY

Northampton College of Advanced Technology, London, E.C.1

PACKING is one factor determining the texture of a clastic sediment. Pettijohn[1] defines texture as the size, shape and arrangement (packing and fabric) of the component elements of a sedimentary rock. Arrangement is a rather neglected factor; Krumbein and Pettijohn[2], surveying the field of sedimentary petrography in 1938, gave detailed consideration to size and shape but did not mention packing.

Packing is usually considered in terms of systematic arrangements of equal spherical particles and reference is often made to the work of Graton and Fraser[3], who examined several simple regular packs and suggested that these had a geological significance. A much more complete investigation of simple systematic sphere packings has been made[4], but this approach is not likely to yield a realistic representation of the packing in a clastic sediment. With allowance made for the idealized particle the regular model suffers from one great defect: it is supposed to represent a random structure.

Two problems present themselves: (1) How is this random packing to be represented? (2) How can an applicable method be devised whereby determinations of packing textures of real clastic sediments can be made? An attempt has been made to solve problem (1) by using the radial distribution function developed to describe the structure of liquids[5]. A reference particle is chosen and the variation in density around it is represented on a graph of density against distance from the reference particle. This graph effectively shows the radial distribution of the particles around a representative particle and may provide a useful means of describing and comparing the packing textures of clastic sediments. Some fairly elaborate experiments have yielded radial distribution graphs for packs of equal spheres[6,7], the tricky part of these experiments being the measurement of the

three-dimensional position of the particles. Most geological situations present only two-dimensional accessibility and to be useful a technique must allow for this. The method described here relies heavily on the assertion by Prins[8] that random two-dimensional structures have all the essential features of three-dimensional structures. He was referring to packs of similar particles and gave some experimental data.

This article describes three attempts to obtain indications of packing texture for clastic structures. Two of these attempts were on shingle beaches and the third on an orthoquartzite rock. The basic technique adopted for the beach material was to photograph the surface—this gives a two-dimensional representation of the pack—and then choose a random pebble and with it as centre draw concentric circles on an enlarged print. These circles increased in radius by a constant amount each time. The number of pebble centres within each annular zone was counted and tabulated. A structural factor related to the density was calculated by dividing the number of pebble centres in a zone (n) by $2\pi R$, where R was the number of the zone. Fig. 1 shows some pebble centres and zones marked on a print of pebbles from Hythe beach. A sample of pebbles was taken from one spot on Hyth Beach (National Grid reference 61/160340). These we later poured into a tray and photographed. The tec nique worked for this special case, so some photograp of a small area of actual beach surface were taken Dungeness (61/091167), just about at the spot marked on the Lewis and Balchin map reproduced by Steers[9].

The technique for the beach is quite straightforwar A photograph of the beach is taken, with the came carefully adjusted so that the film and the beach surfa are parallel, and an enlarged print with good contrast made. A square unit reference grid is drawn on the pri and each pebble is identified and its centre marked. a reference object is included in the photograph the sca can easily be indicated. The number of pebble centr in each square of the grid is counted; this gives som

idea of the evenness of the distribution and the sizes of the particles. Fig. 2 shows a reference grid for the Hythe pebbles with the number of centres marked. The basic cell of the grid is a square of side 2 cm (all measurements refer directly to the real packing).

The marked position *R*1 refers to the scale reference pebble; this one was noted and measured and the measurement compared to the photographic image. The positions of the reference pebbles used for the determination of packing variation are marked *C*1–*C*5. With one of these as centre concentric circles were drawn on the print, the radii of these circles increasing by a constant factor, in this case 6 mm. The number of pebble centres inside each successive annular zone were counted and tabulated; these provide values of n (Table 1). The circle number is indicated by R. If n is divided by $2\pi R$ a value is obtained which is related to the packing density; this value is plotted against R and the graph indicates the variation in packing density around a typical particle (Figs. 3 and 4). For the Hythe grid the mode pebble occupation of a cell is 5 (11 occurrences) and the mean is 5·8. A square (2 × 2) cell group containing about 22 pebbles was considered a reasonably representative area, that is, around *C*1, *C*4 or *C*5. *C*3 falls in a high-density area, and this is shown by the large value of $n/2\pi R$ for $R = 2$ in Table 1. The opposite is true of *C*2.

The mode pebble size in the sample examined was about 1 cm diameter although the pebbles were far from spherical. The sample was split into smaller samples and the pebbles were assigned to Zingg shape classes; the node shape was oblate (class 1).

Eleven photographs were taken at Dungeness, all fairly close together and near the water's edge. These showed a considerable variation in the particle size in a small patch of beach. Two were selected and the packing details are given here. Figs. 5 and 6 show reference grids, and Fig. 7 shows the comparative distributions. One of these illustrates an unusual case, a large pebble surrounded by much smaller pebbles. The large pebble has been chosen as the centre, and its outline is roughly indicated in Fig. 6. The reference grids have 4-cm cell sides and R increases in steps of 1 cm.

Two photographs in a paper by Heald[10] provide examples of packings in consolidated sediments. These are of two samples of St. Peter sandstone from Missouri. One of these has distinct rounded separate detrital grains and contains no clay; the other is a clay-bearing highly presolved rock with close sutured contacts between the grains; it was collected 2 in. below the first sample. Since the magnification was 55 times, drawing circles

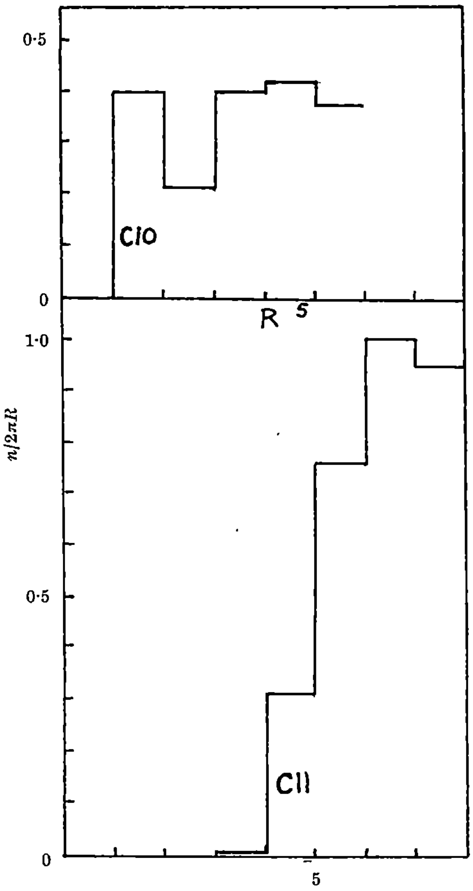

Fig. 7. Radial distributions around pebbles *C*10 and *C*11

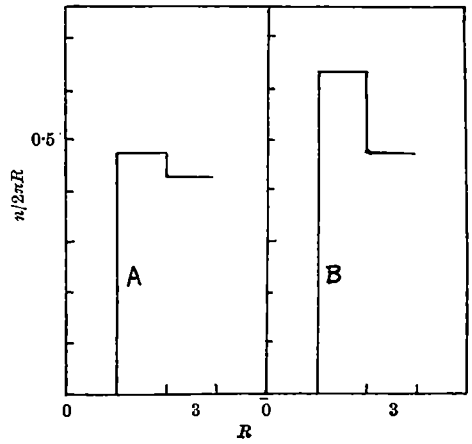

Fig. 8. Packing in sandstone samples; *A*, clay-free sandstone; *B*, sandstone containing clay

with radius increments of 11 mm gave a real value of 0·2 mm. Because of the small size of the photographs only a few circles could be drawn, but the results (Fig. 8) show that a tighter packing is produced in the clay-bearing sandstone. The photographs are too small to give very good results, but with sufficient centres chosen from a large picture and a careful choice of radius increment for the reference circles, packing textures could be easily and conveniently determined.

I thank Ted Willett and Valerie Smalley, both of this College, for their assistance.

SEMICONDUCTION IN KAOLIN

By A. K. CHATTERJI

Central Building Research Institute, Roorkee, India

It has been reported that the electrical conductivity of kaolin increases with temperature[1]. This observation indicates that kaolin may be a semiconductor. In absence of usual confirmatory experiments, an attempt is made here to ascertain the semiconducting nature of kaolin from less direct evidence as adsorption of lime by kaolin in presence of water and rheology of dilute aqueous suspensions of kaolin. The possibility that kaolin may be a ‘*p*’ type semiconductor is indicated.

From the results of measurements on the adsorption of lime at ordinary temperatures by kaolin, kaolin heated at 800° C with or without addition of zinc oxide and of electrical conductivity of these materials at different temperatures, given elsewhere[1,2], it will be seen that at any temperature the electrical conductivity of kaolin, previously heated with zinc oxide, is lowest and that of unfired kaolin is highest[1]. Amount of lime chemisorbed from saturated lime water at ordinary temperatures, in a given time, is highest in kaolin fired with zinc oxide and least in unfired kaolin[2]. This antiparallel behaviour of lime adsorption and electrical conductivity means that the reaction between lime and kaolin in the presence of water is a semiconductor surface reaction which may either be an ‘*n*’ type reaction on ‘*p*’ type semiconductor or vice versa depending on the type of semiconduction of kaolin.

It is stated that, at the temperatures worked with, kaolin previously fired at 800° C has higher conductivity than kaolin which has been similarly fired with zinc oxide[1]. Thus on addition of an ‘*n*’ type semiconducting oxide (ZnO) the conductivity of fired kaolin is lowered. This may occur, if the semiconduction in fired kaolin is predominantly by ‘holes’, through the combination of these with the electrons introduced by ZnO. Again, kaolin fired at 800° C has lower conductivity than unfired kaolin[1]. This may indicate that the effect of dehydration is to remove ‘holes’ from unfired kaolin (dehydration taking place through transfer of ‘holes’ from the crystal). Thus, kaolin may be a ‘*p*’ semiconductor itself; effect of dehydration and heating it with ‘*n*’ type semiconducting oxide is to change it into a more and more ‘*n*’ type semiconducting oxide.

In a recent communication[3] the rheological behaviour of dilute aqueous suspensions of some reactive solids, as lime, portland cement and plaster of paris, has been explained on the assumption that the reaction between these materials and water is a chemisorption process. In such a process the position of the bulk Fermi-level in the particles controls the coverage of chemisorbed molecules. The coverage determines the volume over which stabilization of water lattice takes place and the viscosity of the suspension depends on the extent of the volume over which water structure is stabilized. It is concluded that the rheological behaviour of such suspensions is controlled by the position of bulk Fermi-level in the particles in suspensions. Again, plasticity of clay–water systems has been explained on the assumption that in such a system a layer of water is rigidly attached on the surface of the clay mineral[4]. The nature of the interaction between the water layer and the clay mineral surface is, however, uncertain. Assuming that a chemisorption process is occurring, hydroxyl groups may get attached on the surface of the clay mineral through a transfer of electrons from the crystal (‘*n*’ type reaction) as in the reactions between portland cement, clinker and water[6], and lime and water[7]. If it were so, then the rheological behaviour of dilute suspensions of kaolin in water would be controlled by the position of bulk Fermi-level in the crystal: viscosity will increase or decrease as the position of the Fermi-level is raised or lowered. For the present purpose one has to know what would happen to the viscosity of aqueous suspensions of kaolin which has been previously allowed to react with lime in the presence of water. It has been found that dilute aqueous suspensions of kaolin, so treated and then washed and dried, have lower plastic viscosity than similar suspensions of H-kaolin[5]. This means that, on reacting with lime, Fermi-level of kaolin has been lowered. This can only happen when the reaction between lime and kaolin in the presence of water is an ‘*n* type reaction. With the reaction type settled, the antiparallel behaviour of lime adsorption and electrical conductivity would mean that kaolin is a ‘*p*’ type semiconductor, provided the assumption regarding the nature of interaction between kaolin and water is correct.

The electrical nature of kaolin appears to be similar to that of portland cement clinker. Possibility of the latter behaving as a ‘*p*’ type semiconductor has been indicated elsewhere[6]. The hydraulic action of cement clinker also increases with the decrease of electrical conductivity of clinker[6] as in the case of adsorption of lime by kaolin in the presence of water. Parallelism in the nature of these reactions is clear. The Fermi-level appears to be the controlling factor.

It is concluded that there is a possibility that kaolin may be a ‘*p*’ type semiconductor and that some of its physical and chemical properties may be controlled by the position of bulk Fermi-level in it. The latter suggestion should also be true for other silicates which may prove to be semiconductors. This approach, then, will open a new aspect of chemistry and technology of such silicates.

LETTERS TO THE EDITOR

ASTROPHYSICS

Structure of the Solar Chromosphere

The suggestion of Biermann[1] and Schwarzschild[2], that the radially increasing temperature of the solar atmosphere is to be ascribed to propagation of non-thermal energy, such as acoustic waves, is now generally accepted. The effect of magnetic field, and the possibility that the energy-carrying waves are of a magnetohydrodynamic character rather than acoustic, has been considered seriously[3]. However, the fact that the density and temperature of the chromosphere are significantly affected by magnetic field only when the field attains the strength ($\sim$ 50 gauss) which is found only in localized regions (plages) on the Sun's surface indicates that magnetic field is not of primary significance. Hence one may attempt to understand the energy propagation and its effects on the assumption that one can ignore the magnetic field and so consider only acoustic waves.

Although the acoustic waves generated at the photosphere by granular convection are estimated to be of small amplitude[3,4], it has been recognized that these waves may build up into shock waves, which would bring about a drastic increase in the absorption of the acoustic-wave energy. In a uniform gas, discontinuities are developed in waves of arbitrarily small amplitude if the waves propagate sufficiently far, but one should not expect this phenomenon to occur in an atmosphere in gravitational equilibrium, with which we are concerned, with wavelengths comparable with the scale height. This is because the dispersion relation for plane acoustic waves propagating vertically[4] is:

$$\omega^2 = \omega_0^2 + a^2k^2 \qquad (1)$$

where a is the speed of sound given by:

$$a^2 = \frac{\gamma kT}{m} \qquad (2)$$

if the gas is behaving adiabatically, and the resonant frequency, ω_0, is given by:

$$\omega_0 = \frac{a}{2H} \qquad (3)$$

where H is the scale height given by:

$$H = \frac{kT}{mg} \qquad (4)$$

In an ionized gas we must give to m the value of the average particle mass, and take $\gamma = 5/3$. We see from equation (1) that waves which are harmonically related in frequency are not harmonically related in wave-number and vice versa; hence one would not expect that the non-linear interaction between waves which leads to the generation of shock fronts would occur for waves of arbitrarily small amplitude.

There is another important way in which waves propagating in a 'resonant' medium defined by the dispersion relation (1) differs from waves in a non-resonant medium for which $\omega_0 = 0$. In a non-resonant medium, k decreases with height if the temperature increases with height, and this leads to refraction of rays away from the vertical. In a resonant medium, we observe that ω_0 decreases with height if temperature increases with height, and this will lead to an increase in k if the wave is launched with a frequency close to the resonant frequency, with the consequence that the wave would be refracted towards the vertical. Since the maximum value of ω_0 is the lower bound of the frequency pass band, and since this frequency (corresponding to a 5-min period) for the solar atmosphere is high compared with the turbulence frequency spectrum, we expect that the acoustic energy is carried principally by waves close to the cut-off frequency. Hence one may expect that, in the medium and high chromosphere, the acoustic waves are propagating almost vertically. This picture is in agreement with observations on vertical motions in the chromosphere reported by Leighton[5].

We now consider the energy carried by vertically propagating acoustic waves. If the waves were purely sinusoidal with a maximum flow velocity v_f, the energy density would be $\frac{1}{2}nmv_f^2$, half in kinetic and half in potential energy. Hence the energy flux per unit area, s, is given by:

$$s = \frac{1}{2}\, nmM^2a^3 \qquad (5)$$

if we write $M = v_f/a$ (the 'Mach number' of the flow) and approximate the group velocity by a. This equation may be re-written as:

$$n^2T^3 = \frac{4m}{\gamma^3k^3}\,\frac{s^2}{M^4} \qquad (6)$$

or, approximately:

$$n^2T^3 \approx 10^{23.9}s^2 \qquad (7)$$

if we consider 'Mach 1' flow ($M = 1$). The observed values of n and T for the solar atmosphere[6] are compared with curves s = const. in Fig. 1.

We see from Fig. 1 that the temperature begins to increase when the curve (n,T) intersects the curve $s = 10^5$ ergs cm^{-2} sec^{-1}. This is what one would expect if the energy flux of acoustic waves in the chromosphere at 4,000 km height and above has this value. If the value of temperature did not increase, the waves would have M values in excess of unity, leading to the formation of shock waves and enhanced dissipation; this would lead to local heating of the chromosphere. If, on the other hand, the temperature were to increase significantly more than required by the curve s = const., the acoustic waves would have M values below unity, so that no shock waves would be formed and there would be no heating of the chromosphere.

My assumption that a wave forms a shock only if $M \sim 1$ is a departure from the usual assumption that acoustic waves of arbitrarily small amplitude will form shocks[4]. This difference was ascribed to the form of the dispersion relation (1), which implies that waves which are harmonically related in frequency are not harmonically related in wave number; so that the non-linear wave interaction responsible for the build-up of shocks from small-amplitude waves is inhibited.

The present model enables one to understand the sharp transition from the chromosphere to the corona. The dispersion relation for waves in a medium with thermal conductivity $\varkappa$ is found to be[7]:

$$\omega\left(\omega^2 - \frac{\gamma kT}{m}\,k^2\right) = -\,i\,\frac{2}{3}\,\frac{\varkappa}{k}\,\frac{k^2}{n}\left(\omega^2 - \frac{kT}{m}\,k^2\right) \qquad (8)$$

In most of the chromosphere $\varkappa$ is sufficiently small that there is no dissipation due to thermal conductivity.

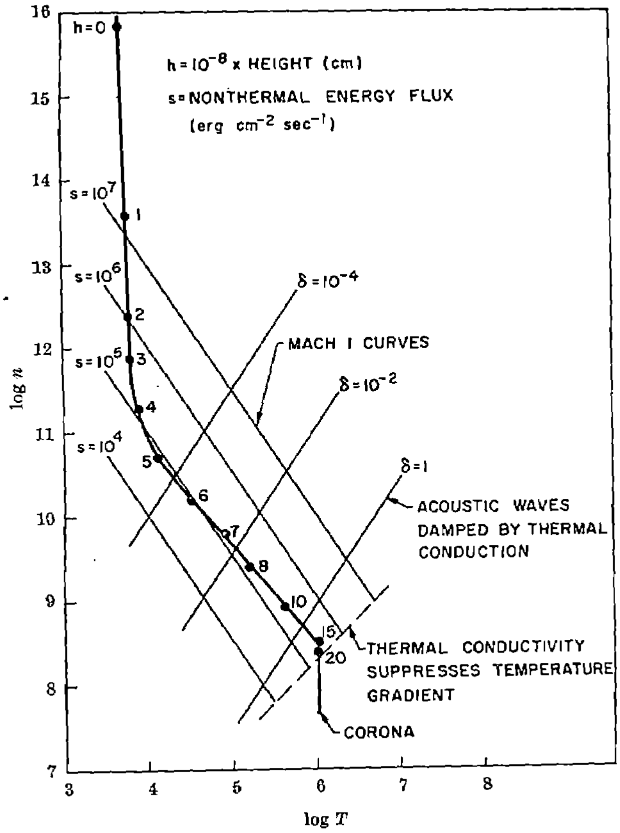

Fig. 1

It is clear from the form of equation (8) that the dissipation depends on the parameter δ, defined by:

$$\delta = \frac{2}{3}\frac{\kappa k^2}{nk\omega} \tag{9}$$

which is given approximately by:

$$\delta \approx T^{3/2} n^{-1} \tag{10}$$

if $\omega = 10^{2.3}$ and we adopt $\kappa = 10^{-6}T^{5/2}$, appropriate for a highly ionized gas[8]. The dissipation is small if δ is either small compared with unity or large compared with unity and is significant only if δ is near to unity. Curves δ = const. are shown in Fig. 1 and indicate that the transition from chromosphere to corona occurs just above the height at which thermal dissipation becomes significant.

Another effect of thermal conductivity is that the downward heat flux can become substantial. It will clearly be impossible to maintain the rise in temperature when the downward heat flux becomes comparable with the flux of acoustic energy. Hence it can be asserted that the transition to the corona must come about before the condition:

$$\kappa H^{-1}T = s \tag{11}$$

is satisfied. By using equation (7), this may be expressed as:

$$n = 10^{2.3}\, T \tag{12}$$

This curve also is shown in Fig. 1, and it is seen that the transition to the corona has occurred before this line is crossed.

The value $s = 10^5$ ergs cm^{-2} sec^{-1} represents a total power input of $10^{27.7}$ ergs sec^{-1} into the corona, a value which fits well with the estimates of energy loss from the corona made by Osterbrook[3]. We may note that the loss of energy by the solar wind is of the same magnitude if the plasma velocity is 500 km/sec and the plasma density about 10 protons cm^{-3} at the Earth's orbit.

Gravitational Collapse

THE stellar-like radio sources ('quasars'), of which 3C48 and 3C273 are examples, appear to be objects with very small diameters yet the total energies of which lie in the range 10^{60}–10^{61} ergs. At the moment, the only source that has been imagined for the production of such high energies, is the Newtonian gravitational potential energy of a highly compressed mass. If a mass equal to some 10^8 solar masses could be compressed into a sphere the diameter of which equalled that of the orbit of Pluto, a gravitational potential energy of the required order of magnitude would become available. During the past thirty years a number of authors have shown that a compression of this kind is predicted by Einstein's equations of general relativity. It is postulated that the only force acting is the gravitational self-attraction of the material, that the density is uniform throughout the spherical mass at each instant of time and that the pressure is always zero. The last condition implies that the material remains at the absolute zero of temperature throughout the collapse to a small volume. These assumptions lead to the conclusion that, for such zero-pressure configurations, the motion continues until a singular state is reached in which the volume occupied by the material tends to a zero value whereas its density becomes infinite. The time of collapse is very short: at best it occurs in a few hundreds of thousands of years, but it may also be over in a matter of weeks or days, depending on the initial conditions.

I have been able to find a solution of Einstein's equations in which the restriction to zero pressure is removed. Both the pressure and the density are, however, uniform at each instant of time, but both rise to infinite values at the end of the collapse. When this happens the volume of the configuration is not zero, but has a small finite value. The time of collapse is also shortened as compared with the time for the corresponding zero-pressure case.

I have also shown how the zero-pressure solutions can be fitted to the external (vacuum) Schwarzschild solution of Einstein's equations. I have failed to establish this property for the solution with pressure. In order to examine this point, as well as a number of others which are mathematically too complicated to analyse through Einstein's equations, I have turned to a combination of classical gas-dynamics and Newtonian gravitational theory. It proved possible to establish the following results: (1) There are classical analogues of the zero-pressure general relativity motions which mimic them very closely and in which the motion is adiabatic. (2) Classical gas-motions with a non-zero pressure are possible but they are non-adiabatic. This means that energy must be extracted from the collapsing configuration if the motion is to continue. I conjecture that this is the reason why, in the general relativity case, the motions with pressure cannot be fitted to an external vacuum Schwarzschild field. The appropriate external field would presumably be one in which energy was present. (3) It is possible to solve with comparative ease the classical equations when pressure-gradients are present, in contrast to the situation in general relativity. The pressure-gradient, of course, provides an additional force which opposes the gravitational collapse. A specific example shows that the time of collapse is lengthened and that the configuration can finally come to rest with a volume of finite magnitude.

These investigations will be published in detail in the August 1964 issue of the *Astrophysical Journal*.

GEOPHYSICS

Combined Effects of Drift and Diffusion in the *F*2 Region

The latitude distribution of f_0F_2 characteristically exhibits an anomalous equatorial trough which we shall refer to as the Appleton anomaly[1,2], although there is evidence[3] that earlier workers were aware of the dip angle dependence of $M_{\max}$ reported by Appleton. Results are available showing the variation of N with dip below the peak[4,5], and more recently satellite results have been reported for the topside electron density[6].

These satellite results have stimulated some theoretical interest[7], although, of course theoretical studies have been made continually[8–10] since Martyn's early proposal[11,12] *that the cause of the Appleton anomaly is a noonday upwards electrodynamic drift communicated from the dynamo regions. (In magnetohydrodynamics this drift may be re-interpreted as an outwards motion of the magnetic lines of force.)*

Theoretical studies have been hindered by the mathematical complexity of the fundamental $F2$ region diffusion equation[9,13–15], and we report here a simple examination of the problem of a self-maintained equilibrium layer in the absence of electron production and loss. It is sufficient to assume the electron density profile at the dip equator to be given, and we refer the reader to recent investigations of the $F2$ layer[16–18] which explain the method more fully.

We first observe that in the $F2$ layer N varies only slowly with respect to the dip angle I. Consider a small element of plasma being carried upwards by electrodynamic drift at right angles to a magnetic line of force as shown in Fig. 1. In the diagram, material is carried across the lines of force from A to B with speed $v^{\perp}$. But, provided AC is not large compared with AB, the electron density at C is the same as the electron density at A, where AC is horizontal. It follows that with this restriction, the significance of which will be discussed later, the drift at right angles to a magnetic line of force is equivalent to a drift v'', parallel to a line of force, such that if I denotes the dip angle:

$$v'' = v^{\perp} \cot I$$

The equilibrium diffusion-drift equation may then be transformed into an equation in one variable, and integrated under suitable boundary conditions. As in the absence of drift, individual lines of force may be regarded as isolated, using the equivalent drift v'', where the aforementioned approximation holds. In what follows we assume, in absence of other information, that $v^{\perp}$ is equivalent to a uniform drift w vertically upwards such that:

$$w = v^{\perp} \cos I = v'' \sin I$$

However, although we shall work in terms of the perpendicular height z above a fixed reference-level, the fundamental drift is the equivalent drift v'' and the fundamental equation is the diffusion equation along a line of force.

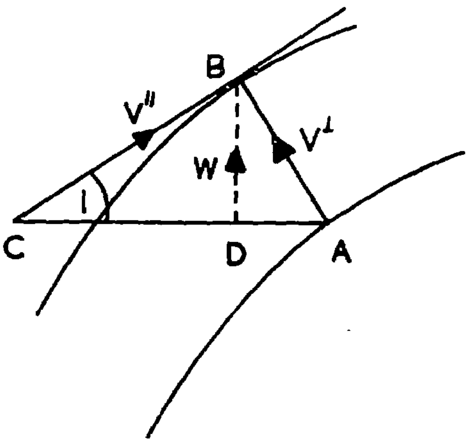

Fig. 1

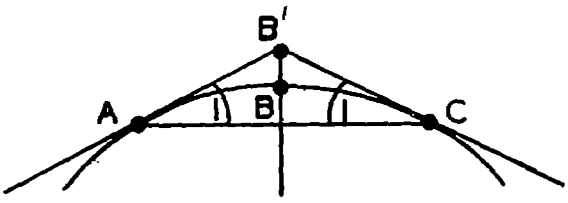

Fig. 2

Ferraro (private communication) has pointed out that the plane stratified $F2$ layer diffusion equation[19] is in fact of far wider application than is commonly supposed. This equation will be used here and the curvature of the Earth will be neglected. We suppose further that the electron density on the dip equator is given to be a Chapman profile with maximum electron density N_{m_0}, scale height H and height of maximum z_{m_0}, and that this boundary condition is to be applied to obtain a local solution of the fundamental equations under conditions of symmetry about the dip equator by replacing the problem at every field point by a straight field line problem. This is illustrated in Fig. 2. The solution at points A and C for the curved field line ABC is assumed to be approximated by the solution for the field line $AB'C$.

Denote by D the coefficient of diffusion, by H_1 the scale height of the neutral constituent and by H_2 the scale height of the ionized constituent. Then we define constants D_0 and w_0' by:

$$D = D_0 \exp(z/H_1)$$

and:

$$w_0' = wH_1/D_0$$

We also write:

$$w_0 = w_0' \operatorname{cosec}^2 I$$

Denote by x the horizontal distance from the dip equator, so that if a line of force crosses the equator at height z_0:

$$z = z_0 - x \tan I$$

Then we find, after reduction which will be reported elsewhere, that a solution of the equilibrium diffusion equation with drift is:

$$N = f(z + x \tan I) \exp(-z/2H_2 - w_0 e^{-z/H_1})$$

where f is an arbitrary function of $z + x \tan I$. Imposing the condition of a Chapman profile at the equator $x = 0$, evaluates f, giving:

$$\begin{aligned} N(x,z) = N_{m_0} \exp\tfrac{1}{2}[1 &- (z-z_{m_0})/H \\ &+ (H_2^{-1} - H^{-1})\, x \tan I \\ &- 2w_0\, e^{-z/H_1}(1 - e^{-x \tan I/H_1}) \\ &- e^{-(z+x \tan I - z_{m_0})/H}] \end{aligned}$$

Taking different equatorial profiles would, of course, give different solutions. To interpret these results for a curved field line model we put:

$$\tan I = 2 \tan (x/r_0)$$

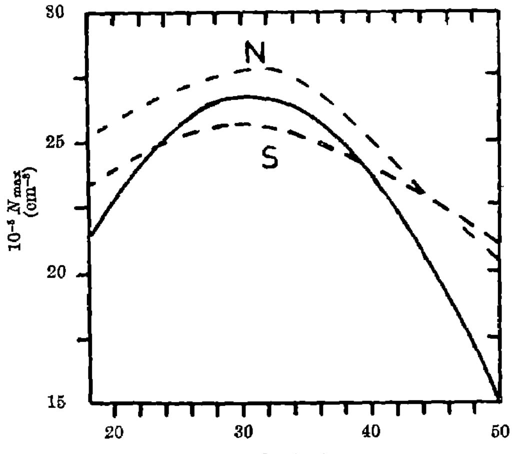

Fig. 3. The broken lines marked *N* and *S* denote measurements made by Croom *et al.* (ref. 4). The solid line represents our theoretical results

where r_0 is the mean geocentric distance of the *F*2 layer (= 6,550 km). Because the electron density varies appreciably over a vertical distance of 100 km and over a horizontal distance of 500 km we expect the aforementioned results to hold for:

$$\sin I \gg 0{\cdot}2$$

that is (say) for dip angles rather larger than 12°.

Fig. 3 shows a comparison of these theoretical results with measurements for:

$$H = H_1 = 100\text{ km}, H_2 = 107\text{ km}$$

The values of z_{m0} and w_0' are irrelevant since in the regions considered $x \gg H$ or H_1 and the curves obtained have the same shape for all values of z_m and w'. The theoretical curve was multiplied by a suitable constant, corresponding to N_{m0}, in order to give agreement in magnitude at the latitudinal maximum.

Generation of Whistler Waves by Helical Electron Beams

SEVERAL investigations[1] published within the past few years deal with the interaction of a stationary plasma in the outer regions of the ionosphere (exosphere) with an assembly of charged particles trapped in the Earth's magnetic field. Such an interaction results in electromagnetic radiation within the audible range which is detected at the Earth's surface in the form of continuous white noise or whistlers. The trapped particles spiral around the lines of the magnetic field B_0 and form a 'helical beam', characterized by velocity components $\beta_\perp c$ and $\beta_\parallel c$ which are, respectively, perpendicular and parallel to B_0 (c is the velocity of light). A whistler wave thus produced and aligned in the direction of B_0 is usually described by the equalities:

$$\omega \approx \tilde{\omega} \equiv ck\beta_\parallel + \Omega_e(1 - \beta^2) \qquad (1)$$

$$F_p \equiv c^2k^2 - n^2\tilde{\omega}^2 = 0 \qquad (2)$$

in which ω is the frequency, k is the wave number, $\beta^2 = \beta_\parallel^2 + \beta_\perp^2$, Ω_e is the electron gyrofrequency, and $n = \omega_e^2/\omega(\omega - \Omega_e)$ is the refractive index for the whistler mode (ω_e is the plasma frequency).

The relationship (1) represents the condition of resonance, that is, the characteristic frequency $\tilde{\omega}$ of the whistler wave is equal to the Doppler shifted electron gyrofrequency. Equation (2) represents the dispersion equation for the stationary plasma which is valid only in the absence of the perturbation produced by the beam. The whistler waves described by equations (1) and (2) will be designated as whistler *P*-waves.

The purpose of this investigation is to point out that the *P*-waves described by equations (1) and (2) are not the only type of whistler waves which can be excited by a helical beam. There are also whistler *B*-waves which are resonant with the beam in accordance with equation (1) but do not satisfy the dispersion equation (2). Thus the plasma-beam interaction results in a *P*-instability and a *B*-instability. In a *P*-instability the growing waves (*P*-waves) result from the excitation of corresponding stationary waves in an undisturbed plasma. If the intensity of the beam is sufficiently small, the frequency of an excited whistler *P*-wave differs very little from the corresponding whistler wave in the undisturbed plasma. If the beam is linear, that is if the electrons in the beam have trajectories aligned along the direction parallel to that of B_0 ($\beta_\perp = 0$), there is only one type of instability[2] (*P*-instability). On the other hand, if the beam is helical ($\beta_\perp \neq 0$), there is an additional instability (*B*-instability) which gives rise to excited *B*-waves. A *B*-instability occupies a relatively wide frequency range in the neighbourhood of a *P*-instability and represents a continuation of the *P*-instability along the frequency axis.

The properties of the whistler *B*-waves are determined from the analysis of the dispersion equation for the plasma-beam system. This equation has the form[3]:

$$F_p + \sigma F_b = 0 \qquad (3)$$

in which $F_p \equiv c^2k^2 - n^2\omega^2$ represents the stationary plasma and σF_b is the perturbation produced by the beam. It is assumed that the perturbation is small, that is, $\sigma \ll 1$, where σ is the ratio of the beam density to the plasma density. One has[3]:

$$F_b = -\,\omega_e^2(1-\beta^2)^{\frac{1}{2}}\left[\frac{\omega - ck\beta_\parallel}{\omega - ck\beta_\parallel - \Omega_e(1-\beta^2)^{\frac{1}{2}}} + \frac{\beta_\perp^2(c^2k^2 - \omega^2)}{2[\omega - ck\beta_\parallel - \Omega_e(1-\beta^2)^{\frac{1}{2}}]^2}\right] \qquad (4)$$

Following the procedure of Zheleznlakov[3], one assigns in the dispersion equation (4) a real value of k and solves the equation for ω. The roots of equation (4) are represented as $\omega = \tilde{\omega} + \delta$, where $\tilde{\omega}$ is the frequency of a resonant wave defined in equation (1). An instability occurs when $\text{Im}\ \delta < 0$ and $|\text{Im}\ \delta|$ denotes the rate of growth of an excited wave.

It is usually assumed that mono-energetic electrons (characterized by fixed values of $\beta_\parallel$ and $\beta_\perp$) can excite only a single frequency *P*-wave described by equations (1) and (2)[1]. However, it follows from equation (4) that such a beam can excite not only a single frequency

P-wave but also a continuously distributed frequency spectrum of whistler B-waves.

When $\beta_{\parallel} \ll \beta_{\perp}$ the helical beam becomes 'almost circular'. This would occur, for example, near a mirror point for particles spiralling along the lines of the Earth's magnetic field. In such cases the possible occurrence of a P-wave within the range of whistler frequencies depends on the magnitude of the transverse velocity component $\beta_{\perp}$. A whistler P-wave can be excited only when electrons in the almost circular beam are relatively energetic. The transverse velocity component $\beta_{\perp}$ of such electrons must be larger than approximately 0·97. When $\beta_{\perp}$ is smaller than approximately 0·97, an almost circular electron beam cannot excite a whistler P-wave. It does excite, however, B-waves which occupy the entire whistler frequency range and are characterized by the rate of growth $|\text{Im}\ \delta|$, which is as follows:

$$|\text{Im}\ \delta| = \frac{\sqrt{2}}{2}\,\sigma^{\frac{1}{2}}\,\omega_e(1-\beta^2)^{\frac{1}{2}}\,\beta_{\perp} \tag{5}$$

It is noted that the rate of growth as given in equation (5) is independent of the frequency of the wave. The excited B-wave moves in the direction opposite to that of the beam.

It is generally recognized that a whistler P-wave moves in the direction opposite to that of the beam[1]. It represents, therefore, a 'counterstreaming instability'. It should be noted in that connexion that there are two whistler P-waves excited by an almost circular electron beam when $\beta_{\perp}$ is sufficiently large. One of these waves does indeed represent a counterstreaming instability. However, the other wave moves in the direction of the beam and its phase velocity exceeds the velocity of the beam. Therefore, it represents a 'sub-luminous instability'[2]. Both the counterstreaming and sub-luminous P-instabilities have frequencies in the immediate neighbourhood of $\Omega_e(1-\beta_{\perp}^2)^{\frac{1}{2}}$.

PHYSICS

Simultaneous Sampling at Different Altitudes

A MODIFICATION of the technique reported earlier[1] for making simultaneous measurements at widely separated heights in the atmosphere is described. This promises to be more successful for heavier loads.

In the previous publication a balloon carried a cone of nylon cord with equipment to be exposed at two levels. At about 70,000 ft. one piece of equipment which was tied to one end of the cord was released and this fell freely, unwinding rapidly the string from the cone. The other end of the string was tied to the balloon which also supported the second piece of equipment. Some successful flights were obtained using nylon string lengths of 10,000–27,000 ft. supporting loads of 300 g wt. hanging from level balloons at about 90,000 ft. (The nylon used was 840 denier, which had a breaking strain without knots of 5,000 g wt.)

The new technique uses the same nylon cord but this is wound on a reel which has oil damping. Owing to the lower speed of fall of the equipment during this damped unwinding process compared with that for the previous flights, the magnitude of the impulse on the string at the end of the unwinding is reduced. One flight only has been performed using the modified equipment, and this tested the technique and recorded the pressure at both levels. In this case the supported equipment hanging from the lower end of the string consisted of a mass of about 900 g. The mass of string and load totalled 1,500 g. This equipment consisted of a double 30″ paper corner reflector and a clock with pressure recorder.

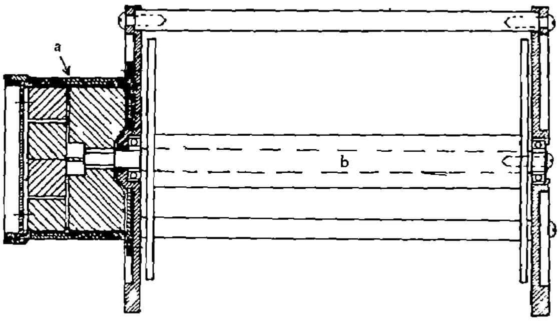

Fig. 1. Reel used for suspension of equipment. *a*, Oil damping chamber; *b*, axle of reel. Mass of reel 1,100 g. Mass of string 600 g

A diagram of the reel used is shown in Fig. 1. The oil damping device at (*a*) consists of six blades each of area 7·5 cm² rotating in oil of *SAE* 140 and set at an angle of 20° to the rotating axis (*b*) of the reel. Attached to the fixed outer part of the oil chamber are a further six blades each of area 4 cm² set parallel to the axis, but slightly off centre. A series of parallel grooves on the inside cylindrical wall of the oil container allows the oil to circulate in the chamber. This device was tested by releasing equipment from the top of a 150-ft. high building and recording rates of fall for temperatures of oil ranging from 20° to 27° C.

A string joint was made by tying the string to a 1-in. diameter intermediate ring made of aluminium rod 1/8 in. in diameter. It was found that the strain at breaking point using this practice could be increased by a factor of 1·3 compared with that for tying string to string using a clove hitch with 3 half-hitch knot. The weight of the reel was 1,100 g and an additional radar target and pressure recorder were tied to the balloon so that a record was available of variations of balloon height. Flight was terminated using the clockwork device described earlier[1]. The flight curve is shown in Fig. 2. It will be observed that the rate of fall of the equipment during the unwinding process was constant over most of the time of fall.

To carry heavier loads including, say, radiosondes, etc., it will be necessary to increase the string denier proportionally, and it is planned to proceed with applications of this technique to cosmic ray measurements.

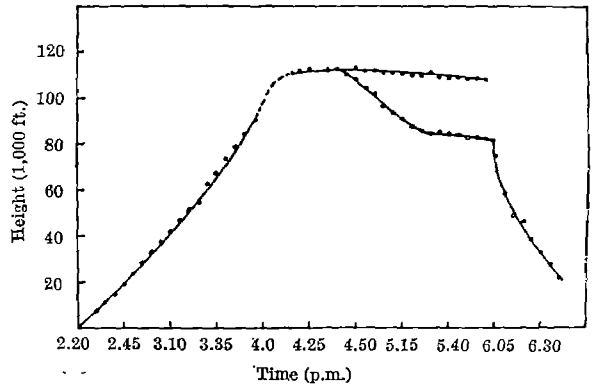

Fig. 2. Height–time curve of balloon and suspended equipment as measured by 3-cm radar (string flight 2.4.64, plastic balloon *WF*2)

We thank Mr. K. Maxwell, Mr. D. Arnold and Mr. W. Carruthers for assisting with the design and testing of the reel.

Trapped Charges on Dielectrics

It has been proposed[1] that the charge produced on a dielectric surface by electrical discharges is the result of trapping of electrons at impurity or defect sites in the material. Although numerous experiments on surface charges have been reported[2,3], no direct evidence for a trapping process has been obtained. Assuming that the electrons are held in traps of thermal energy W eV, the probability of escape per second may be expressed as:

$$B = A \exp(-W/kT)$$

where A is a constant, k is Boltzmann's constant and T is the absolute temperature. The charge density decay rate is then given by:

$$q/q_0 = \exp(-Bt)$$

In order to determine whether the behaviour of a surface charge is consistent with a trapping process, the decay rate at different temperatures has been measured for several dielectric materials using an electrometer technique.

A schematic diagram of the apparatus is shown in Fig. 1. A disk of the dielectric, 25 mm in diameter and 4 mm thick, is fitted into a recess in a circular brass plate so that rotation of the plate causes the centre of the dielectric disk to pass under a point electrode and, later in the rotation, under an electrometer probe, which are both fixed vertically above the plate. The probe is a screened and highly insulated 0·8-mm diameter copper wire. Its measured capacitance, including the co-axial lead to the electrometer valve, type *ME*1403, is 104 *pF*. The probe, electrode and plate are in a temperature-controlled oven. The plate rotates at 2,850 r.p.m., so any charge on the dielectric induces a voltage pulse on the probe every 21 msec. The dielectric is charged when it is under the point electrode by applying a 100-μsec negative voltage pulse to the electrode, the timing of the pulse being controlled by an interrupted light-beam and a photocell. The resulting pulse train on the probe is amplified and displayed on an oscilloscope, which is triggered by the charging pulse. It is recorded photographically, using a time-scale of the same order of duration as the time-constant of decay of the charge on the disk. The experiment is repeated at several temperatures, and the rates of decay are afterwards determined by projecting the photographs on to a calibrated screen.

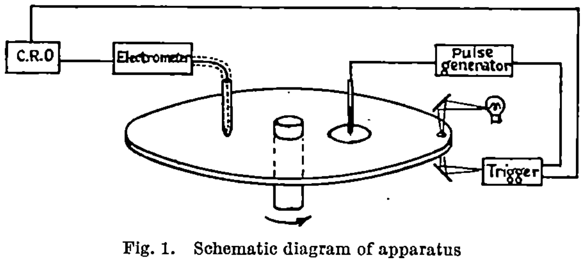

Fig. 1. Schematic diagram of apparatus

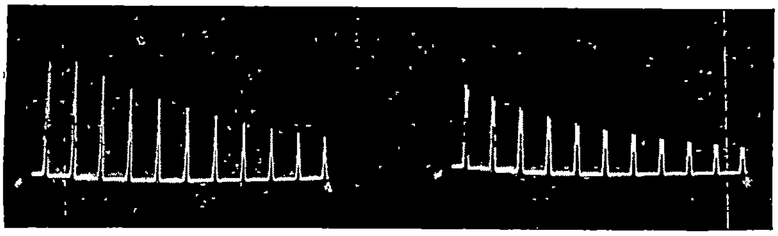

Fig. 2

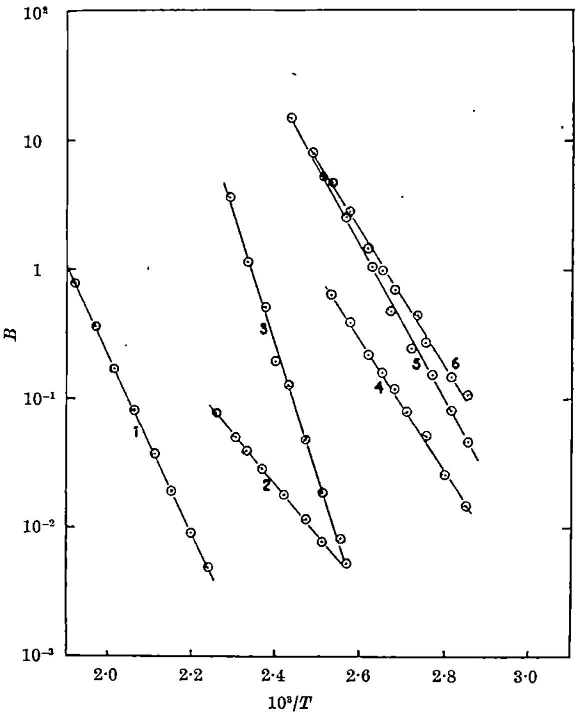

Fig. 3. 1, Polystyrene; 2, polythene; 3, polymethylmethacrylate; 4, potassium iodide; 5, sodium chloride; 6, potassium chloride

Fig. 2 shows traces obtained with a disk cut from a single crystal of sodium chloride at 129·5° C after a 5-kV and an 8-kV charging pulse. The decay characteristics are identical; but a spontaneous loss of charge has occurred after the 8-kV pulse, accounting for the smaller amplitude and more complex form of the record. The surface charge density may be calculated from the expression $q = KCV$, where C is the probe input capacitance, V is the voltage pulse measured on the oscilloscope and K is a constant. K is a function of the probe cross-section and the amplification of the electrometer and is about 35 cm^{-2}. The maximum signal in Fig. 2 is 0·4 V and so the charge density is approximately 10^{-9} coulomb cm^{-2}. This is nearly the maximum charge density that may be attained in air since the breakdown field of air under normal conditions is about 30 kV cm^{-1}. The loss of charge on increasing the charging pulse amplitude is thus probably the result of local discharges.

Experimental values of the coefficient B for disks cut from single crystals of sodium chloride, potassium chloride and potassium iodide, and disks cut from sheet polymethylmethacrylate, cross-linked polythene and cross-linked polystyrene are shown in Fig. 3, plotted as log B against the inverse of the absolute temperature. The linear plot obtained in each case indicates that a single activation energy is involved, and hence that the decay of charge may be described by diffusion of electrons through the volume of the material via the defect traps. An electron trapping and diffusion process has been shown to be operative in the alkali halides[4], the traps being vacant cation sites (Schottky defects) which capture electrons, forming *F*-centres. The electron traps in the plastic materials remain to be identified.

A surface charge is effectively a space-charge (in the absence of conducting films on the surface) and so the procedure described above affords a direct method of determining the thermal energy of the traps active in space-charge-limited solid state devices[5].

It is noted that for a positive frictional charge obtained in an experiment with polythene, by pressing a brush on to the surface while the plate was rotating, the decay parameters were the same as those obtained for the negative, electrically produced charge.

Propagation of Stress Pulses across a Liquid-Steel Boundary

Experiments have been carried out in which pressure pulses, of about 40-μsec duration, are propagated across a plane liquid–steel interface. For this purpose a slightly modified form of the apparatus described by Bull[1] was used.

The liquid was contained in a vertical steel cylindrical tube fitted with a steel piston at its lower end and the upper end open. The tube was of length 3 ft., internal diameter ⅞ in. and external diameter 1¼ in.

A pressure pulse was generated in the piston by firing a lead bullet of 0·22-in. calibre so as to strike the lower end of the piston normally at its centre. As a first approximation it was assumed that the (pressure, time) curve of this pulse was rectangular in shape, of amplitude P, and of duration T (the time of impact of the bullet); in these experiments P was about 600 atm. and T about 40 μsec. When the front of this rectangular compression pulse reached the upper surface of the piston a fraction α was reflected and a fraction $(1-\alpha) = \beta$ transmitted into the liquid. Since the incident pulse was in the steel, this was a case of reflexion at a rarer medium because the acoustic impedance of the liquid was less than that of the steel. Thus the pulse, of amplitude βP, transmitted into the liquid was of the same sign as the incident pulse while the reflected pulse, of amplitude $-\alpha P$, in the steel was a pulse of tension. When this reflected pulse, of tension reached the lower surface of the piston it was reflected as a compression pulse of the same amplitude, and on its arrival at the liquid–steel interface a fraction α of it was reflected as a wave of tension and a fraction β transmitted into the liquid. The cycle was then repeated and so on. In this way a number of successive pulses of compression of amplitudes βP, $\alpha\beta P$, $\alpha^2\beta P$, etc., was propagated upwards through the liquid column. Each was of duration T in time and the fronts of the pulses followed one another at time intervals of $\tau = 2L/c$, where L is the length of the piston and c the velocity of the pulses in the steel. If $L < c\tau/2$ the individual pulses in the liquid would overlap in time. If, however, $L > c\tau/2$ the individual pulses would be propagated upwards without overlap in time; this was arranged to be the case by using a piston of length 13 cm.

The behaviour of these pulses was studied by means of a steel pressure bar of length 6 ft. and diameter ½ in. inserted into a 'porthole' about 2 ft. above the bottom of the liquid column. The recording technique was the condenser method developed by Davies[2], in which the (displacement, time) curve of the motion of the outer end of the bar was determined as an oscillogram; differentiation of this curve then gave the (pressure, time) curve of the events occurring in the liquid.

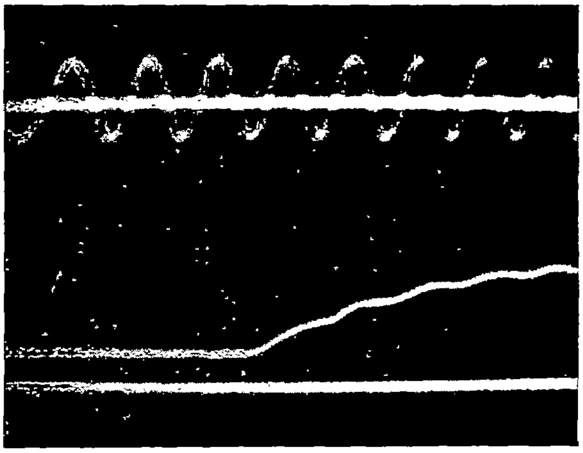

Fig. 1. Upper trace, timing wave, period = 50 μsec.; middle trace, condenser unit signal; lower trace, datum line

An example of the type of oscillogram obtained using water is shown in Fig. 1. The separate displacements due to the successive pulses are clearly shown on the 'staircase' type of trace obtained; the timing wave is of frequency 20 kc/s. An analysis of this trace enables two results to be obtained. First, the time of impact T of the bullet may be obtained by averaging over four pulses; this turns out to be 39·1 μsec, which agrees well with other methods of determination. Secondly, the velocity c of the pulses in the steel may be obtained by measuring the time lag τ between successive 'knees' on the oscillogram; averaging over four pulses it is found that τ = 51·9 μsec and thus:

$$c = \frac{2 \times 13}{51{\cdot}9 \times 10^{-6}} = 5{\cdot}01 \times 10^5 \text{ cm/sec}$$

which is in good agreement with the accepted value.

The next step which suggests itself is the use of calibrated strain gauges mounted on the pressure bar so that the (pressure, time) curves of the individual pulses may be obtained directly; this procedure should then enable a value of α, the reflexion coefficient between steel and the liquid, to be obtained.

RADIATION CHEMISTRY

Effect of γ-Radiation on Deoxynucleoprotein acting as a Primer in RNA Synthesis

It has been found[1] that on irradiation of calf-thymus deoxynucleoprotein (DNP) the major part of the radiation damage occurs on the protein moiety of the DNP and that, in fact, the DNA itself is largely protected from the effects of radiation. This would be in agreement, for example, with the structure of DNP as proposed by Wilkins[2]. Since it has been suggested that the protein (histone) in DNP is a regulator of RNA synthesis and thus of protein formation[3], it seemed of interest to examine the effects of radiation on DNP and DNA when acting as primers for RNA synthesis.

DNP was prepared by the method of Zubay and Doty[4]. Calf-thymus DNA was a gift from Prof. M. H. F. Wilkins. The appropriate RNA polymerase was prepared from *M. lysodeikticus* by procedure *B* of Nakamoto, Fox and Weiss[5]. Radioactive labelled and unlabelled nucleoside triphosphates were obtained from Schwartz Bioresearch Inc. Irradiations of aqueous solutions of DNA and DNP (0·02 per cent. in DNA) were carried out with a 500-c. cobalt-60 γ-ray source and assayed using (^{3}H)CTP as a tracer. The acid-insoluble alkali-soluble products were estimated using a Packard Tri-Carb scintillation counter.

The results for the DNA primed synthesis show that under these conditions a dose of 2,000 rads is sufficient to reduce the priming activity by 50 per cent and a dose of 12,000 rads lowers it to 2 per cent of the original activity (Fig. 1). These results are similar to those obtained by Harrington[6] and are in contrast to previous experiments concerning the DNA primed DNA-synthesis[7,8].

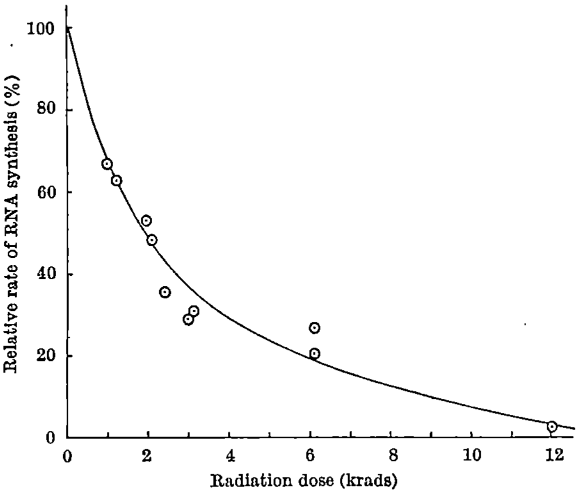

Fig. 1. Effect of radiation (cobalt-60 γ-rays) on DNA (calf thymus) acting as primer in RNA synthesis. The incubation mixture contained: 1 μM each of ATP, GTP, CTP, UTP; 20 μc. (^{3}H)CTP, 3·0 μM Mn^{2+}; 50 μM *tris* buffer (*p*H 7·4), 1·6 μM spermidine phosphate, 80 μg DNA, 60 μg protein (polymerase), in a final volume of 1 ml. Incubation was for 30 min at 30° C

However, with deoxynucleoprotein an entirely different response is obtained (Table 1). In unirradiated systems the priming activity of DNA when 'complexed' as deoxynucleoprotein is only about 25 per cent of that of an equivalent amount of 'free' DNA. Moreover, on irradiation of deoxynucleoprotein with a dose of 12,000 rads only a 30 per cent reduction in RNA synthesis is observed. However, on further irradiation, the priming activity of the deoxynucleoprotein rises until at 72,000 rads its activity is approximately 40 per cent greater than that of the unirradiated DNP.

Table 1. DEOXYNUCLEOPROTEIN-INDUCED RNA-SYNTHESIS

Effect of radiation (cobalt-60 rays) on the priming activity of calf thymus nucleoprotein (DNP)

Radiation dose (krads)	RNA synthesis (%)
0	100*†
12	72
18	82
24	81
36	112
48	133
72	138

Each tube contained: 1·0 μM each of ATP, GTP, UTP, 0·1 μM CTP (labelled with 20 μc. (^{3}H)CTP), 3·0 μM Mn^{2+}, 10 μM phosphate at *p*H 7·4, 160 μg DNP, 180 μg protein (polymerase), in a final volume of 1 ml. Incubation was for 30 min at 30° C.

* Corresponding to 200–300 μμM nucleotide incorporated depending on the experiment. Each result is the average of 4 or 6 experiments.

† Under the same conditions DNA-induced RNA synthesis corresponds to 408 per cent.

These results can be interpreted by assuming that in the normal state of DNP the protein (histone) is not attached to the DNA throughout the length of the molecule and it is the 'non-complexed' DNA which acts as primer for RNA synthesis as suggested by Huang and Bonner[3].

The radiation appears to attack the non-complexed DNA as indicated by the initial drop in the RNA synthesis, and further, as irradiation proceeds, fresh DNA is 'uncovered' to act as primer. This would suggest that one of the actions of radiation is to cause the protein sheath to become detached, to a lesser or greater extent, from the DNA.

If, in a living cell, the histone does, in fact, act as a gene controller, irradiation of the deoxynucleoprotein could cause two effects. First, the production of 'normal' messenger-RNA would be severely curtailed, because of the effect of the radiation on the free DNA; secondly, new messenger-RNA's could be produced which would not normally be formed. Such effects would cause severe imbalance of the cell's metabolism. It has also been suggested that the amount of histone complexed with the DNA varies during the cell cycle[9]; in that event, a mechanism such as outlined here could also account for the variability of radiation sensitivity during the cell cycle.

We thank Dr. S. B. Weiss for making available to us some unpublished results and also Mr. M. G. Robinson of this laboratory for preparation of nucleohistone.

CHEMISTRY

Effect of the Spreading Solvent on Monolayer Properties

EFFECTS of the spreading solvent, rate of compression, and substrate water on monolayer properties have been the subject of much discussion[1–11]. Most attention has been directed at the spreading solvent. Volatile solvents are used to aid spreading and to facilitate accurate measurement of minute quantities of film-forming materials. One possible source of difficulty is retention of solvent in the monolayer; a second is effect of the solvent on the state of aggregation of the film material (size and shape of islands); a third is dissolution and spreading by the solvent of paraffin wax used in coating parts of the apparatus (float and foils).

The first and second sources are under investigation but present experimental difficulties. Significant information has now been obtained on the third source by measurements on a film balance completely free of wax and related contaminants. The trough and bridge are coated with unpigmented '*TFE* Teflon', the float is solid '*TFE* Teflon', and the thin flexible foils are made of '*FEP*

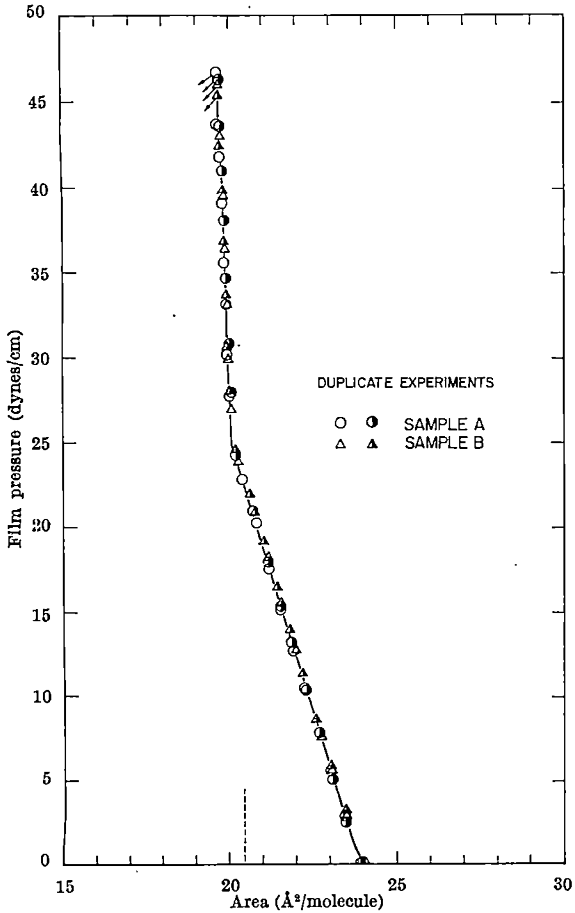

Fig. 1. Pressure-area isotherms for stearic acid spread from benzene

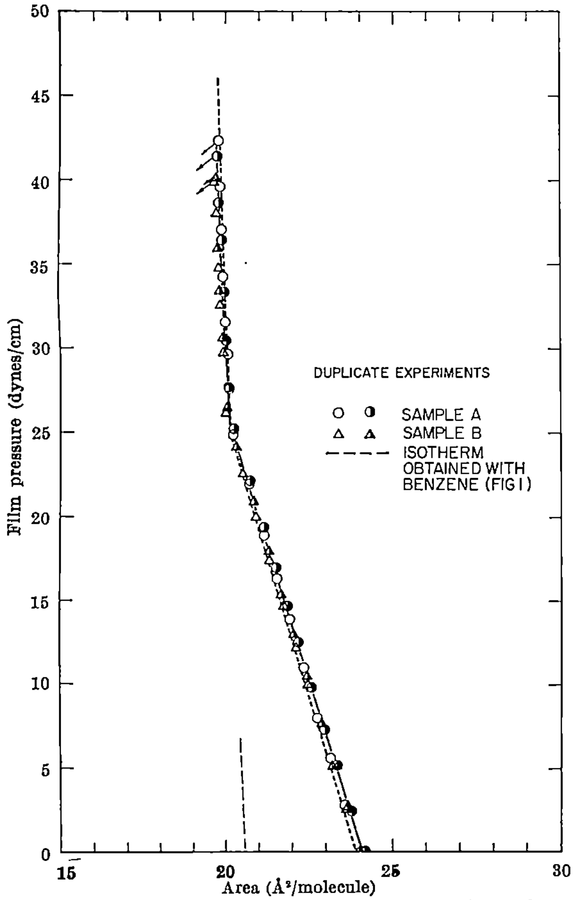

Fig. 2. Pressure-area isotherms for stearic acid spread from *n*-hexane

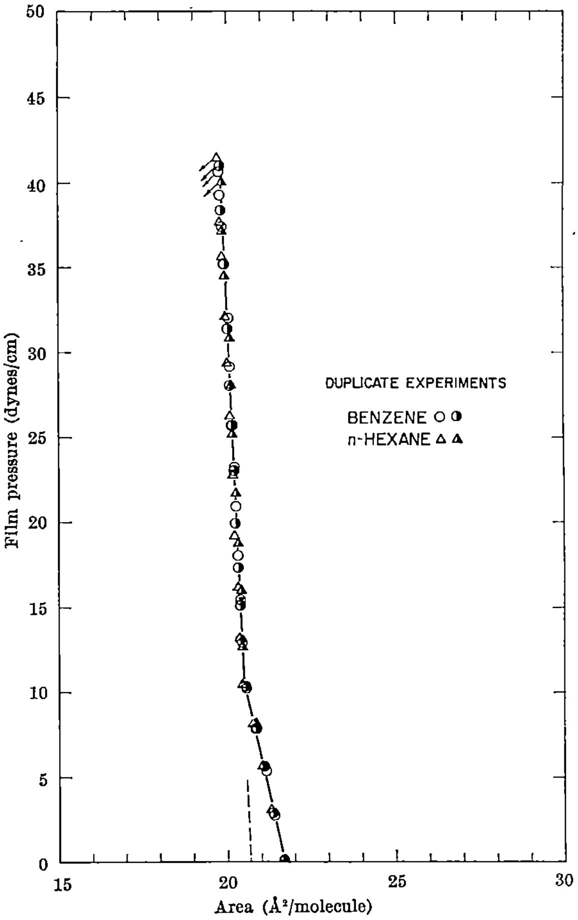

Fig. 3. Pressure-area isotherms for cetyl alcohol spread from benzene and from *n*-hexane

Teflon' heat-sealed to the float and bridge. Surface pressures were continually balanced during incremental compressions of about 3 dynes. Time intervals between readings were one minute throughout. The substrate water was held at 25° ± 0·1° C by internal thermostating of the trough.

Experiments were performed with two high-purity samples of stearic acid, the classical compound in monolayer studies, and with cetyl alcohol, the principal film-forming compound for retardation of water evaporation. Pressure-area isotherms were determined for these materials spread from benzene and from *n*-hexane that had been passed through silica gel and then distilled. The substrate water was twice distilled in quartz; it had a specific conductivity of about 0·5 μmhos.

Isotherms for stearic acid are shown in Figs. 1 and 2. They are identical for the two solvents except for a small difference in collapse pressure. Extrapolated areas for the two linear segments are 20·5 and 23·8 Å²/molecule. In earlier work with stearic acid, the linear segments at high pressures had coincided[3,5]. At low pressures, however, isotherms obtained with benzene had shown an appreciably larger area. Evidently small amounts of wax (from the float and/or foils) or other contaminants had been dissolved more effectively by benzene than by *n*-hexane. The wax occupies area at low pressures but is squeezed out at high pressures. Recent experiments in which small quantities of wax were introduced into the spreading solution support this interpretation.

There is a small difference in collapse pressure: with benzene, 46; with *n*-hexane, 42 dynes/cm. Isotherms obtained recently for stearic acid spread without a solvent show a collapse at 51 dynes/cm, but are identical in contour. Thus, at the highest pressures *n*-hexane may be interfering more than benzene, or benzene may be a better spreading solvent. Collapse pressure, however, depends somewhat on the rate of compression. Variation of collapse pressure with rate of compression for films spread from benzene indicates a collapse pressure close to 42 dynes/cm for a 1·5 min interval; this is in agreement with earlier experiments performed in this laboratory.

Isotherms for cetyl alcohol spread from the two solvents also coincide, as shown in Fig. 3. Extrapolated areas for the two linear segments are 20·7 and 21·7 Å²/molecule. Collapse pressures of about 41 dynes/cm agree within experimental error for monolayers spread from the two solvents.

In recent pressure-permeability experiments with the evaporometer developed in this laboratory[12], the data for stearic acid and for cetyl alcohol spread from the two solvents effectively coincide. However, reproducibility with benzene is superior. Details of the apparatus and procedure used to obtain both the pressure-area and pressure-permeability isotherms will be described later.

Isotope Effect in Radical Reactions

THE first demonstration that molecules differing only in their isotopic constitution could be separated by the technique of gas chromatography was made by Wilzbach and Riesz[1], who used a packed column to separate deuterated and tritiated *cyclo*hexanes. Later, Cartoni *et al.*[2] showed that capillary columns were more efficient for this purpose, and achieved a separation of all the deuterated benzenes on a 500-ft. column. Cvetanovic[3] demonstrated the value of this technique in the examination of radical reactions, being able to separate the products of the combination of protonated and deuterated alkyl radicals.

In the present investigation, an 80-ft. cupro-nickel capillary column, coated with squalane, was used to separate the pairs, *cyclo*hexane–perdeutero*cyclo*hexane, benzene–perdeuterobenzene and toluene–toluene-αd_3. The separations achieved are illustrated in Fig. 1.

This technique was used to investigate the insertion of methylene into *cyclo*hexane by the photolysis of diketene in the presence of a mixture of *cyclo*hexane and perdeutero*cyclo*hexane. The mixture was divided into two fractions, one of which was passed immediately through the gas chromatography apparatus, and the second irradiated with light of wave-length 3130 Å from a medium pressure mercury vapour arc, so as to photolyse the diketene and produce methylene radicals. After the irradiation was completed (1 h), the products were passed directly to the inlet system of the gas chromatography apparatus. The *cyclo*hexane–perdeutero*cyclo*hexane ratios were thus determined before and after reaction and k_H/k_D calculated using equation 1.

In a second investigation, the effect of methyl radicals on the *cyclo*hexane–perdeutero*cyclo*hexane mixture was investigated by the photolysis of acetone with light of wave-length 3130 Å in the presence of the mixture in the gas phase. An average value for k_H/k_D is given in Table 1.

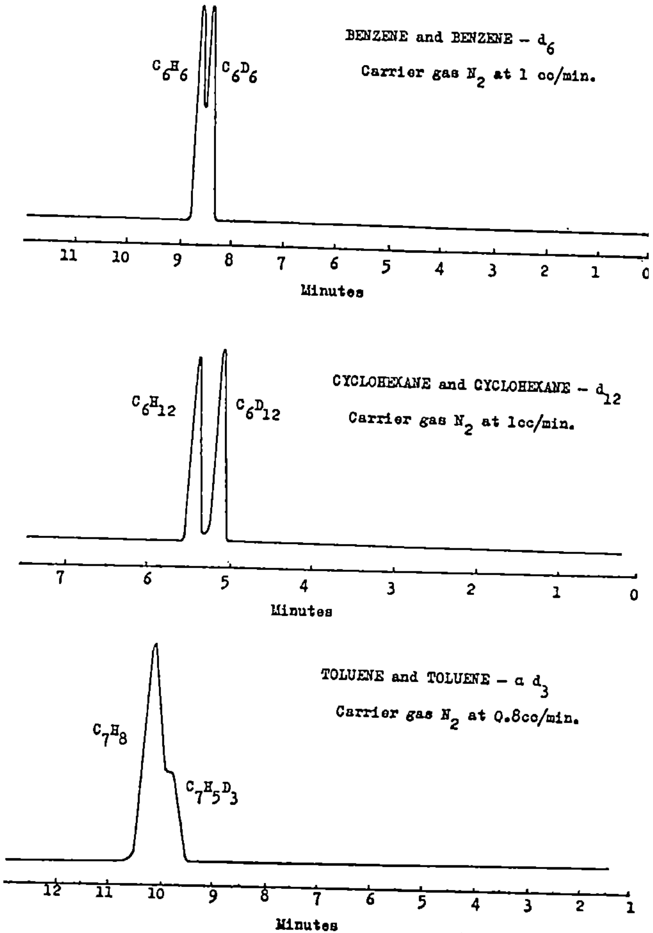

Fig. 1. Separation on the 80-ft. capillary column

Finally, the mixture was submitted to mercury photosensitization by irradiating the *cyclo*hexane–perdeutero*cyclo*hexane mixture alone with light of wave-length 2537 Å from a low-pressure mercury vapour arc. In this case, the results obtained from gas chromatography were checked by the use of a mass spectrometer (A.E.I. *MS* 2).

Table 1. ISOTOPE EFFECT

Reaction	k_H/k_D
Methylene insertion in *cyclo*hexane	0·7
Hydrogen abstraction from *cyclo*hexane	0·37
Mercury photosensitization of *cyclo*hexane	2·7
Reaction of methyl radicals with benzene	0·73

If the initial concentrations of *cyclo*hexane and perdeutero*cyclo*hexane are $[C_0^H]$ and $[C_0^D]$ and the final concentrations are $[C_1^H]$ and $[C_1^D]$, then the ratio of the rate constants for the disappearance of the two species k_H/k_D can be expressed as:

$$\frac{k_H}{k_D} = \log_{10}\frac{[C_1^H]\,[C_0^H]^{-1}}{[C_1^D]\,[C_0^D]^{-1}}$$

Before reaction, the ratio is C_0^D/C_0^H $(=A)$, and after reaction, in which n per cent conversion occurs, the ratio is C_1^D/C_1^H $(=B)$. A and B are the ratios which are determined by gas chromatography and also by mass spectrometry. But:

$$[C_1^H] = \left(1-\frac{n}{100}\right)[C_0^H]$$

and

$$[C_1^D] = \left(1-\frac{n}{100}\right)[C_0^H]\,B$$

therefore

$$\frac{k_H}{k_D} = \frac{\log(1-n/100)}{\log B/A(1-n/100)} \qquad (1)$$

The isotope effect has been calculated from this last equation and the results are given in Table 1.

It can be seen that a usual isotope effect is obtained in the case of the mercury photosensitized reaction, a finding which is consistent with the accepted concept of the process as a transfer of energy from the excited mercury atom followed by a scission of a C–H bond.

$$C_6H_{12} + Hg^3P_1 \rightarrow C_6H_{12}{}^* + Hg^1S_0$$

$$C_6H_{12}{}^* \rightarrow C_6H_{11} + H$$

In the methylene reaction and hydrogen abstraction by methyl radicals, an inverse isotope effect is indicated. In these two reactions, however, a secondary C–H bond is broken and a primary C–H bond is formed.

$$C_6H_{12} + CH_2 \rightarrow C_6H_{11}CH_3$$

$$C_6H_{12} + CH_3 \rightarrow C_6H_{11} + CH_4$$

Thus both these reactions are exothermic and if the exothermicity of the reaction for the C–D bond interchange is greater than that for the C–H bond interchange, then perdeutero*cyclo*hexane would be expected to disappear more rapidly from the reaction system.

Recently, Gray and Thynne[4] have determined the isotope effect in the abstraction of hydrogen atoms from methylamine by methyl radicals.

The isotope effect was also found to be reversed for the attack of methyl radicals on benzene and perdeuterobenzene. Here, however, the situation is more complicated because, although some hydrogen abstraction does take place at room temperature, the predominant reaction is addition of the radicals to the benzene ring to form a complex:

$$C_6H_6 + CH_3 \rightarrow C_6H_6CH_3$$

which may disappear by dimerization or by reaction with a second methyl radical.

It would be difficult to predict the value of the isotope effect for such a reaction.

The value of the gas chromatographic method in the determination of the isotope effect of chemical reactions lies in its extreme simplicity and accuracy. In all cases where the results of gas chromatographic analyses were compared with those produced by mass spectrometry, good agreement was obtained.

Fluoroketone Hydrates: Helix-breaking Solvents for Polypeptides and Proteins

It is well known that compounds which form strong hydrogen bonds can disrupt the intramolecular hydrogen bonds in synthetic and natural polypeptides. For example, urea in large amounts (about 20 per cent by weight of solution) causes the helix–coil transition in aqueous solutions of ribonuclease[1]. Various organic compounds, particularly acids, have also been reported to effect these transitions. Notably, trifluoroacetic acid (TFA)[2] and dichloroacetic acid (DCA)[3] have been used with success. For synthetic polypeptides, the evidence for helix–coil transitions has been obtained from measurements of intrinsic viscosity[3] and, more conveniently, optical activity[4].

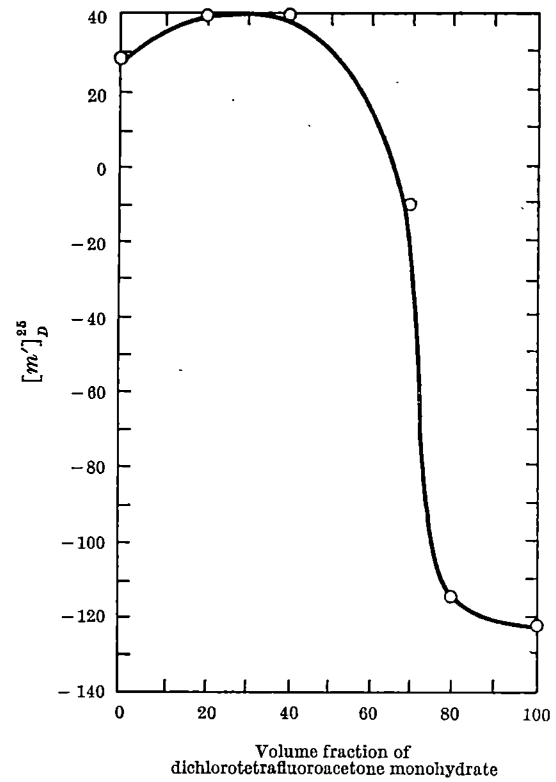

Fig. 1. Effective molecular rotations of solutions of poly-γ-benzyl glutamate

It appears that TFA forms more powerful hydrogen bonds than DCA[4,5], but tends to degrade the peptide bonds. The latter effect is borne out by a decrease in intrinsic viscosity[3] and fluorination of the polymer[6].

I have found that hydrates of fluoroketones are solvents for synthetic polypeptides and some proteins and apparently form more powerful hydrogen bonds with the peptide group than does TFA. However, the solutions do not suffer from the degradative effects of TFA and are comparatively stable over long periods of time.

Two fluoroketones have been investigated. Dichlorotetrafluoroacetone was converted to a monohydrate by adding the stoichiometric amount of water. (The precise structure of this hydrate is uncertain, and it probably exists in equilibrium with a dissociated, acidic form. This problem has been the subject of spectral investigations which will be reported elsewhere[7].) Hexafluoroacetone was dissolved in water to form a hydrate containing about 1·6 moles of water to 1·0 of ketone. (This mixture is liquid at room temperature and is more convenient to manipulate than the 1·5/1 hydrate, which is a solid at room temperature.)

The evidence for dichlorotetrafluoroacetone monohydrate effecting a helix–coil transition was obtained from measurements of the optical activity of solutions of poly-γ-benzyl glutamate (PBGA) in mixtures of the fluoroketone hydrate with chloroform. The results are shown in Fig. 1, in which we have plotted [*m'*], the effective molecular rotation (as defined by Moffit and Yang[8]) given by:

$$[m']_D^{25} = [\alpha]_D^{25}\left(\frac{3}{n_D^2 + 2}\cdot\frac{M}{100}\right)$$

where $[\alpha]_D^{25}$ is the specific rotation, n_D the refractive index appropriate to the particular solvent and M the residue molecular weight of PBGA.

The volume fraction of dichlorotetrafluoroacetone monohydrate necessary to effect the transition is about 65 per cent, which compares with 70 per cent of DCA required in mixtures of ethylene dichloride and dichloroacetic acid[4]. Furthermore, the specific optical activity ($[\alpha]_D^{25}$) of the solution of PBGA in the pure dichlorotetrafluoroacetone monohydrate is more negative than for other solvents. The value of −72·6° for ($[\alpha]_D^{25}$) may be compared with values of −17·5° and −46° for DCA and TFA, respectively[5]. Presumably this large negative value reflects the powerful solvating effect of the solvent for the peptide group.

The stabilities of these solutions are revealed by the inherent viscosity, defined as $\eta_{\text{inh}} = (\ln\ \eta_r)C$, where η_r is the relative viscosity at some concentration C g/dl. If C is small, then η_{inh} is not too different from the intrinsic viscosity $[\eta]$. At 60° C the inherent viscosity of a 0·4 per cent solution of PBGA in TFA fell to 50 per cent of its original value (1·8 dl/g) in 10 h, whereas over the same period of time the inherent viscosity of a solution in the dichlorotetrafluoroacetone monohydrate fell by only 7 per cent. After 30 h at 60° C, the η_{inh} of the TFA solution had decreased by 70 per cent, but that of the solution in the hydrate had decreased by only 11 per cent.

In a second series of experiments, silk fibroin was found to be soluble in and to exist as a random coil in the hydrates of dichlorotetrafluoroacetone and hexafluoroacetone. The results are shown in Fig. 2. The procedure was to measure the optical activity in the pure hydrate and then in mixtures with increasing amounts of a weaker solvent to the point of precipitation of the silk. The results are substantially similar to previous measurements with dichloroacetic acid[5].

Finally, ribonuclease was found to dissolve in dichlorotetraacetone monohydrate but to have been denatured when recovered. However, mixtures of the hydrate with water might be effective in breaking the helix without causing denaturation, but this point was not investigated.

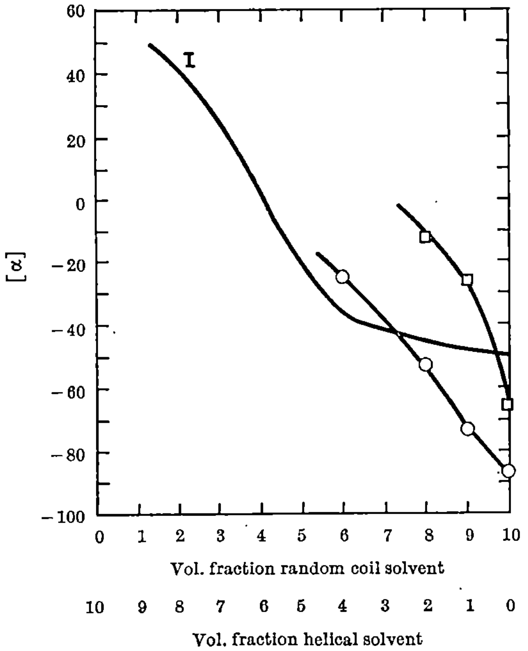

Fig. 2. Specific rotations of solutions of silk fibroin. I, Ethylene dichloride-dichloroacetic acid (ref. 4); ⊙ chloroform–dichlorotetrafluoroacetone monohydrate; □, dioxane–hexafluoroacetone-1,6-hydrate

I thank Prof. W. H. Stockmayer for his advice.

A Quaternary Alkaloid from *Croton turumiquirensis*, Stayerm.

A GREAT deal of work has been done on oil of *Croton*[1] but the genus as a whole has received little attention from the chemical point of view. Some alkaloids have been reported and the structures of some of these have been established[2]. Recently, in connexion with work in these laboratories on the volatile oils of Venezuelan species of *Croton*[3], we noticed that aqueous extracts of many of the local species gave positive tests with alkaloid reagents such as Maeyer's, Dragendorf's and Vassler's. No alkaloid could be extracted into organic solvents so the base present was assumed to be quaternary. The bark of the trees proved to be richest in alkaloid content.

The solution obtained by percolating very dilute aqueous acid through a column of the dried, ground bark of *Croton turumiquirensis* was concentrated at 40° to a manageable volume and then treated with Maeyer's reagent. The voluminous precipitate was collected by centrifugation and, after washing, the alkaloid was obtained from the Maeyer's salt with hydrogen sulphide, in the usual manner. From the concentrated solution pale yellow crystals separated, but even after many recrystallizations the material, although chromatographically homogeneous, showed no melting point but decomposed slowly from 130°. Analysis of this material showed in fact that it was a mixture of alkaloid iodide and chloride, but the analytical figures (organic portion only) suggested the molecular formula $C_{42}H_{52}N_2O_9^{++}$ (found, C, 69·2; H, 7·5; N, 3·7; O, 19·6 per cent; $C_{42}H_{52}N_2O_9$: requires, C, 69·4; H, 7·2; N, 3·8; O, 19·8 per cent).

Using ion exchange resin ('Amberlite *IRA* 400') the mixed salt was converted to the pure iodide, m.p. 235° (decomp.) (found, C, 51·1; H, 5·3; N, 3·2; O, 14·3; I, 26·3 per cent; $C_{42}H_{52}N_2O_9I_2$: requires, C, 51·3; H, 5·3; N, 2·9; O, 14·6; I, 25·8 per cent). The nitrate, m.p. 240°–241° (decomp.), which was prepared by the addition of dilute silver nitrate solution to an aqueous solution of the base iodide, agreed with the same molecular formula (found, C, 58·6; H, 6·0; N, 6·5; O, 28·9 per cent; $C_{42}H_{52}N_2O_9(NO_3)_2$: requires, C, 59·1; H, 6·2; N, 6·6; O, 28·1 per cent).

The ultra-violet spectrum of turumiquirensine (as we have provisionally called the base) is complex and probably arises from the superimposition of several chromophores ($\lambda_{\max}^{\text{EtOH}}$ 220 mμ (ε = 63,700), 265 mμ (ε = 18,700) and 300 mμ (ε = 15,600)). The spectrum changes on the addition of alkali ($\lambda_{\max}^{\text{EtOH·NaOH}}$ 225 mμ (ε = 69,000), 275 mμ (ε = 13,700) and 315 mμ (ε = 14 000)), suggesting a phenolic hydroxyl, and this is confirmed by the formation of a phenolic acetate in acetic anhydride/pyridine. The infrared spectrum of turumiquirensine iodide shows a broad peak attributable to hydroxyl groups (around 3,170 cm⁻¹) but does not show carbonyl absorption, while the acetylated material (as the iodide) shows additional peaks at 1,780, 1,760 and 1,200 cm^{-1} characteristic of phenolic acetates. At least one hydroxyl group is still present in the acetylated derivative.

The molecular formula and spectral evidence suggested that this base might belong to the *bis*benzylisoquinoline group of alkaloids, but none of the degradations usually effective in this group has afforded interpretable results. Almost all chemical reactions give rise to viscous, highly coloured oils. Similar alkaloids have been found in *C. rhamnifolius*, *C. xanthochlorus*, Croiz and *C. speciosus*, M. Arg.

BIOCHEMISTRY

Fusicoccin: a New Wilting Toxin produced by *Fusicoccum amygdali* Del.

Our attention was directed by Dr. A. Graniti, of the Istituto di Patologia Vegetale of the University of Bari, to the observations of Grosclaude[1] and Graniti[2] that culture filtrates of *Fusicoccum amygdali* Del., the causative agent of a disease of the almond tree (*Prunus amygdalus* St.) common in Italy, exhibited phytotoxic activity. This manifested itself in bringing about the wilting of leaves on small branches of almond trees, such as occurs under natural conditions in the infected plant.

The original strain of *F. amygdali*, given to us by Dr. Graniti, was grown in shake flasks and stirred fermenters. A modified Czapek–Dox medium, containing 3 per cent glucose in place of sucrose, was found suitable for producing the active principle. The fermentations were carried out at 24° C for 3–4 days, when the culture medium showed maximal activity, detectable in a test on young tomato plants after 30–100-fold dilution. The biological assay was run according to the semi-quantitative techniques developed by Gaümann[3] in the course of his detailed studies of wilting phenomena. We are obliged to Dr. Graniti for advice concerning this assay method.

The phytotoxic principle was exhaustively extracted with *n*-butyl acetate from filtered batches of 50–300 l. culture medium, and purified by the following steps: (1) evaporation to dryness; (2) residue taken up in $CHCl_3$ (insoluble fraction discarded); (3) residue from $CHCl_3$ extract taken up in methanol (insoluble fraction discarded); (4) residue from methanol extract washed with hexane to remove lipoid impurities, then taken up in ethyl ether (insoluble fraction discarded); (5) residue from ether extract (usually 20 mg/l. culture fluid) dissolved in about 10 times the volume of chloroform containing 3 per cent acetone, and passed through a 'Florisil' column (1 g for each 3 litres of culture medium) on which the active material was firmly adsorbed. The column was washed with about three column volumes of the same solvent. Fractional elution was effected with chloroform containing 6–10 per cent acetone. The fractionation was followed at first by biological assay and later by thin layer chromatography with chloroform/*iso*-propanol (92:8), using a sulphuric acid spray. During the work it became clear that the phytotoxic activity was due to several substances. The present investigation is concerned with the component present in the largest amount, which proved to be the least polar and migrated faster in the chromatographic test. It was termed fusicoccin *A*.

The fractions containing this active substance were combined and evaporated. The residue consisted of biologically active crystals embedded in an oil which exhibited negligible biological activity. It was filtered through a coarse sintered glass plate to remove the oil and the solid was crystallized from ethyl acetate.

Crystalline fusicoccin *A* showed phytotoxic activity in the tomato plant test in concentration of 0·1–0·2 µg/ml. It is a white solid, m.p. 150°–152° C, soluble in alcohols, ether, chloroform, benzene, insoluble in hexane; it crystallizes readily from esters and *cyclo*hexane. The solubility in water is very low, but the compound can be brought into aqueous solution by first dissolving in a small amount of alcohol.

Elementary analysis indicated the formula of fusicoccin *A* to be $C_{38}H_{58}O_{13}$ (found: C, 63·07, 63·16; H, 8·03, 8·01 per cent; $C_{38}H_{58}O_{13}$ required: C, 63·10, H, 8·03 per cent). It contained one methoxy and two acetoxy groups (direct analysis and nuclear magnetic resonance spectrum), and at least one double bond (one mole of hydrogen taken up on catalytic hydrogenation). It is optically active, $[\alpha]_D^{25} + 73$ ($c = 0·6$, in chloroform). Molecular weight determination by X-rays (kindly carried out by Dr. M. Bonamico and Prof. A. Vaciago, C.N.R. Research Centre for Structural Chemistry, Rome) gave a value of 733·5 (± 2 per cent); isothermal distillation (kindly carried out by Dr. W. Simon of the Eidgenossische Technische Hochschule, Zürich) gave a value of 697·3 (± 4 per cent). The ultraviolet spectrum showed only strong end absorption. The infra-red spectrum showed the presence of hydroxy and ester (acetate) groups and of unsaturation, and the absence of aromatic structure. The mass spectrum (kindly carried out by Dr. J. S. Shannon, Sydney, Australia) showed a very complex pattern. A peak corresponding to the molecular ion was absent; the highest mass peak was at *m/e* 704, probably due to an ion formed through loss of water molecule from $C_{38}H_{58}O_{13}$ (mol. wt. 722). A similar behaviour was shown by dihydrofusicoccin *A* (prepared by catalytic hydrogenation of fusicoccin *A*, m.p. 151°–153° C), which exhibited the highest mass peak at *m/e* 706, the value expected for the ion derived by dehydration of a $C_{38}H_{60}O_{13}$ compound (mol. wt. 724). Dihydrofusicoccin *A* had about half the biological activity of fusicoccin *A*. On acid hydrolysis (in N sulphuric acid at 100° C) fusicoccin *A* liberated one mole of glucose (identified by paper chromatography and by reaction with glucose oxidase), demonstrating the glucoside nature of the substance. The structure of the aglycone is under investigation.

We have been informed by Dr. Graniti that crystalline fusicoccin *A* after injection into a wound made near the stem of a branch of an intact almond plant produced wilting of the leaves, as occurs after infection with the fungus under natural conditions.

We thank Miss Maria T. Simeoni for biological assays and Mr. B. Santurbano for his chemical assistance.

Specific Inhibition of Anti-Rh Antibodies by Extracts from Twigs of Angiospermous Plants

INVESTIGATION of higher plants, bacteria and viruses for their content of substances related to the human blood groups has been in progress in this laboratory for more than a decade[1,2]. Substances possessing only Rh specificity have not been reported previously by us. Recent attempts to confirm reports on Rh_0(D) blood group specificity for an unidentified strain of *Pseudomonas* and a 'glycopeptide' prepared from it and for L-glucose, rutinose and sialic acids were not successful[3].

Extension of earlier work[1] has now shown that heat-stable non-dialysable substances, which specifically inhibit anti-Rh agglutinins, occur in twigs of the majority of Angiospermae, but they were not found among the Gymnospermae tested. Members of the family Oleaceae—such as *Syringa* (lilac, 9 species tested), *Forsythia* (5 species tested), *Fraxinus* (ash, 4 species tested), *Ligustrum* (privet, 1 species tested), *Chionanthus* (fringe tree, 1 species tested), *Jasminum* (jasmine, 1 species tested), *Osmanthus* (1 species tested), *Phillyrea* (1 species tested)—were more closely investigated.

Samples of twigs showed negligible bacterial or fungal contamination. The twigs were stored at − 20° C until they were worked up. The extraction procedure was based on one previously used in this laboratory[1]. It consisted of chopping the materials in a Waring blender for 10 min with 10–20 times their weight of water. Boiling the samples for 20 min did not affect their activity. The ground suspensions were filtered through gauze, then centrifuged at 2,500 r.p.m. for 15 min, toluene and chloroform were added, dialysis was carried out for 12 h against 25–100 vol. distilled water at 4° C and then for 24–48 h against running tap water. The materials were then concentrated under reduced pressure and their dry weight adjusted between 0·6 and 2·0 per cent with 0·85 per cent aqueous saline, containing 0·025 M phosphate buffer, *p*H 7·2. The final *p*H of all samples was between 6·8 and 7·3.

Human erythrocytes were stored and prepared as described previously[4]. They were used as a 0·5 per cent suspension in buffered saline. All anti-Rh sera listed in Table 1 were of human origin, monospecific and contained saline agglutinating antibodies.

The source and properties of the other agglutinins have been described previously[1,4] as have the serological procedures. All reagents were used in 0·1 ml. volume. Two-fold serial dilutions of test materials were made using a different pipette for each tube. The titrated suspensions were shaken and incubated with 4 minimum agglutinating doses of antiserum for 2 h at 23°–25° C. The appropriate erythrocytes were then added and the tests were read microscopically after one further hour of incubation at 23°–25° C. Each titration series included appropriate controls. An Rh_0(D) active preparation from human erythrocytes was included as standard in the assays with anti-Rh sera[3]. Active materials were tested more than 3 times with each serum. Substances which did not inhibit at concentrations of 5 mg/ml. were considered to be inactive. Activities are expressed in terms of dilution of inhibitor before addition of serum and erythrocyte suspension.

Lilac twigs were picked over a period of 8 months (May–January); there was no significant fluctuation in their content of active material. Table 1 shows representative results. Active preparations inhibited all anti-Rh_0(D) sera tested. In addition to most Oleaceae, strictly specific and similar Rh inhibiting activity was found in extracts from *Sassafras albidum*, which also possessed H(O) activity, *Betula* (birch, 1 species tested), *Platanus* (plane tree, 1 species tested), but *Chionanthus virginicus* and the gymnosperms *Taxus cuspidata* (1 species) and 1 *Pinus* sp. showed no anti-Rh agglutinin inhibiting activity. Also inactive were blood group specific lipopolysaccharides from *E. coli* O_{86} (B active) and *E. coli* O_{128} (H(O) active)[2] as well as 'infectious mononucleosis receptor' from beef and sheep erythrocytes[2]. The lack of Rh_0 specificity of blood group A, B and H(O) human ovarian cyst mucoids[5] was confirmed on specimens prepared in this laboratory. Most plant extracts weakly inhibited (2·5–5 mg/ml.) *Lotus tetragonolobus* extracts in their action on O erythrocytes and lilac also in the S-anti-S system. Boiled, non-dialysable lilac twig extracts were further treated by Sevag's method[6]. The active electrodialysed material, of unchanged activity, was in the aqueous phase.

Control experiments indicated that the inhibiting principle did not attach itself to erythrocytes; determination of the agglutinability showed that neither Rh positive nor Rh negative erythrocytes acquired the inhibiting material when incubated for 1 h at 23°–25° C. Also, no inhibiting material was removed from lilac extract solutions, as demonstrated by their unchanged potency before and after incubation with red cells. The active material had no absorption maximum between 230 and 320 mμ but a plateau between 260 and 285 mμ. Spectrophotometric determinations indicated < 1 per cent of hexosamine, sialic acid and methylpentose.

These results show that material of moderate activity and appreciable Rh specificity could be extracted from the twigs of the majority of the Angiospermae tested. The activity was equal to that reported for the most active preparations isolated from human erythrocytes[3,7]. In contrast to the erythrocyte material which is readily inactivated by heating for 1 min at 56° C or when exposed to 3 per cent ethanol for 24 h, the plant material resisted

boiling and all concentrations of ethanol. Therefore, while activity and specificity are similar to the human receptor substance, as determined in the hæmagglutination inhibition test only, it is likely that the physical and chemical nature of the plant material is different from the human Rh agglutinogen.

The lilac preparations were non-antigenic to 6 rabbits and non-toxic when given (1·2 mg/kg) intravenously or subcutaneously.

We thank Dr. H. T. Skinner, director, National Arboretum, Washington, D.C., and his colleagues for numerous plant specimens, and Dr. A. Konugres, Dr. Ph. Levine and Dr. Ph. Sturgeon for gifts of anti-Rh$_0$(D) sera.

Antioxidants in Oats : Light-induced Isomerization

BY means of thin-layer chromatography on silicic acid we have shown that there are at least six phenolic antioxidants in oats[1]. These substances are esters of the hydroxycinnamic acids, caffeic and ferulic acids. When the preparation of larger quantities by column chromatography was attempted, it was found that additional compounds appeared. We have now shown that these arise from the action of light on the original antioxidants.

By working entirely in the dark or in subdued tungsten lighting, it has been possible to isolate antioxidant components IV and V (single spots on thin-layer chromatography plates); some of their properties are listed in Table 1. The other components have not yet been obtained in a pure state. If exposed to an ultra-violet lamp, or to daylight for as little as 10 min, substances IV and V each give a second spot on thin-layer chromatography (solvent system *A*). It is evident that a sample of the mixed antioxidants prepared in daylight will contain both the isomers of each component. Column chromatography using a solvent mixture similar to *A* may give a series of well-resolved peaks, but each will contain two substances: for example, peak IV will also contain the isomer of V. On further exposure of the eluate to light, equilibrium is re-established with the formation of V and the isomer of IV, and thus three spots appear on the thin-layer chromatogram of the peak. In consequence, the column appears to have a low-resolving power.

Table 1. PROPERTIES OF COMPONENTS IV AND V

Component	Solvent	R_F			M.p. °C	Anti-oxidant activity units/mg	Phenolic products of hydrolysis
		Dark (*trans*)	Irradiated (*trans*)	Irradiated (*cis*)			
IV	*A*	0·42	0·42	0·59	85–86	14	Caffeic acid
	B	0·54	0·51	0·51			Ferulic acid
V	*A*	0·29	0·29	0·41	140–141	39	Caffeic acid
	B	0·28	0·23	0·23			

Thin-layer chromatography on silicic acid containing 2 per cent calcium sulphate; solvent *A*, diethyl ether—light petroleum (b.p. below 40°), 3 : 2; solvent *B*, chloroform—diethyl ether, 4 : 1. Irradiation at 366 mμ, 5 min, 30 cm from 125-W Hanovia lamp, type 11. Antioxidant activity, defined as in ref. 1.

Table 2. THIN-LAYER CHROMATOGRAPHY OF CAFFEIC AND FERULIC ACIDS AND THEIR ESTERS

	Solvent	R_F		
		Dark (*trans*)	Irradiated (*trans*)	Irradiated (*cis*)
Caffeic acid	*A*	0·11	0·10	0·15
	B	0·06	0·05	0·05
Ethyl caffeate	*A*	0·28	0·29	0·41
	B	0·33	0·29	0·29
Ferulic acid	*A*	0·17	0·14	0·24
	B	0·21	0·19	0·19
Ethyl ferulate	*A*	0·43	0·43	0·57
	B	0·65	0·63	0·63

Thin-layer chromatography as in Table 1.

The effect of ultra-violet light on cinnamic acids and their derivatives is to convert them into equilibrium mixtures of their *cis*- and *trans*-forms[2,3]. These isomers can be separated by paper chromatography[4], and the separation of *cis*- and *trans*-ethyl ferulate on a thin layer of silica gel *G* has recently been reported[5]. We have confirmed that when caffeic and ferulic acids and their ethyl esters are isomerized by ultra-violet irradiation, the *cis*- and *trans*-forms are separated by our solvent system *A*, but not by system *B* (Table 2). It would seem that the oat antioxidants easily undergo the same type of isomerization.

Distribution and Fate of 2-Aminoethylphosphonic Acid in *Tetrahymena*

THE recent discovery of 2-aminoethylphosphonic acid (AEP) and its isolation from certain ciliates and from the sea-anemone is of interest, for these reports[1–3] represent the only occasions on which a compound containing a C–P bond has been discovered in biological material. Nothing is as yet known of the biosynthetic pathway by which such a bond is formed. The present communication deals with the initial work on this problem, and is concerned with the distribution of AEP among the cellular components of *Tetrahymena* and the rate of incorporation of ^{32}P-orthophosphate into the molecule.

*Tetrahymena pyriformis Wh*14 grown in axenic culture at 28° in media containing proteose-peptone, yeast extract and glucose attained maximum cell density in about 40 h; 'log-phase' cells were collected at 30 h, and stationary phase cells at 100–120 h.

AEP assay was based on the resistance of the C–P bond to hydrolysis after 48 h exposure to 6 N hydrochloric acid at 110°. Hydrolysates of cells grown in the presence of inorganic phosphorus-32, when subjected to paper electrophoresis followed by autoradiography, contained AEP and inorganic phosphate as the only labelled compounds present. AEP was separated from orthophosphate by chromatography on either 'Dowex 50-*H*' or 'Dowex 1-acetate'.

Preliminary experiments indicated that AEP was present in both the free state and in a bound form, the latter largely in the lipid fraction. This confirmed the finding of Kandatsu and Horiguchi[3], who pointed out that the bulk of AEP in *Tetrahymena* was bound in the lipids. However, examination of the lipid-free residue has revealed considerable amounts of bound AEP in that fraction also; the AEP bound in this residue could not be extracted by a variety of boiling lipid solvents nor by mixtures of methanol and chloroform containing ammonia.

To gain some information about the metabolism of AEP, the rate of incorporation of phosphorus-32 into the molecule was followed under a variety of conditions. Inorganic phosphorus-32 was added to a culture at 17 h, that is, at the beginning of the log phase. Samples of the cultures were withdrawn at intervals and the AEP present in the acid-soluble pool, in the lipid fraction (chloroform-soluble) and in the lipid-free residue was isolated and its specific radioactivity determined. In the 6 h following addition of phosphorus-32, during which the cell density increased threefold, the specific activity of the AEP in all three fractions increased steadily (Table 1), but the increase was most rapid in the lipid-bound AEP and slowest in the free AEP, the residue-bound AEP being intermediate. While the two latter fractions continued to gain in specific activity after that period, the specific activity of the lipid-bound AEP did not increase further, although the cell density continued to increase for some 18 h or more. The reason for this is not known, but it is possible that the cells take up the labelled inorganic phosphate in preference to organophosphates, and only when the former becomes exhausted is the unlabelled organic phosphorus of the medium (yeast extract) used.

Table 1. Specific Radioactivities (10^3 c.p.m./μmole P) of Three AEP Fractions after Addition of ^{32}P-Orthophosphate to Log-phase Suspension of *T. pyriformis*

The cell density (mg dry weight/100 ml.) at the times shown, 1, 6 and 23 h, was 20, 55 and 141, respectively

AEP fraction	Time after ^{32}P addition (h) 1	6	23
Lipid-bound	19	62	65
Residue-bound	11	43	68
Acid-soluble	4·4	17	55

By contrast with the situation in growing cells, little radioactivity was incorporated into the AEP of stationary phase cells (Table 2), even though such cells were able to incorporate the isotope into the non-phosphonic phosphorus of the lipid and residual fractions.

Table 2. Total Radioactivity Incorporation into Some Phosphorus Compounds in Growing and Stationary Cultures of *Tetrahymena*

(Total counts per 25 ml. of suspension, 1 h after the addition of 100 μc. ^{32}P-orthophosphate.) The cell density (mg dry weight/100 ml.) of the log-phase and stationary suspensions was 204 and 272, respectively

Phosphorus fraction	Log phase	Stationary
AEP		
Lipid-bound	19,000	100
Residue-bound	2,500	13
'Ester-P'		
Total lipid P	—	46,000
Total 'residue' -P	—	41,000

The negligible degree of uptake of phosphorus-32 into AEP during the stationary phase confirmed that its synthesis proceeded only during cell growth. It was, therefore, suspected that this compound was associated with the structural elements of the cells, and was likely to represent an end-product of metabolism.

To test this, log-phase cells were labelled with phosphorus-32 and re-suspended in fresh medium containing excess unlabelled orthophosphate, in which growth continued. If AEP was an end-product, then the total label in the AEP per unit suspension volume would remain constant, irrespective of multiplication. However, if AEP was further metabolized, the phosphorus-32 in this fraction would be displaced by 'cold' phosphate and the total AEP radioactivity per unit volume of suspension could be expected to fall with time. The experiment illustrated in Fig. 1 shows that, after an initial rise (presumably due to incorporation of endogenous phosphorus-32), the radioactivity in the AEP per unit volume of suspension remained constant. The lipid- and residue-bound AEP is, therefore, not further metabolized[4].

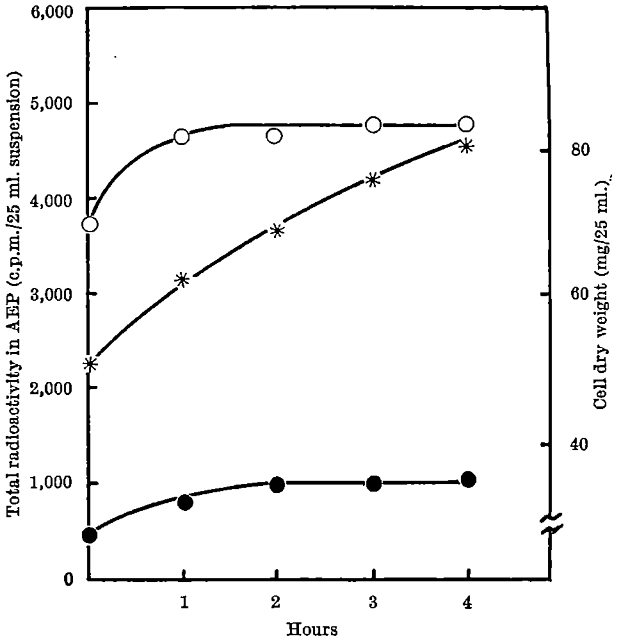

Fig. 1. Time–course of the level of radioactivity in the total lipid-bound (○), and residue-bound (●) AEP in growing *Tetrahymena* suspensions labelled with phosphorus-32 and re-suspended in phosphorus-rich, 'cold' medium. (✱) Cell density

The nature of the residue-bound AEP has been investigated. A portion of this residue, labelled with phosphorus-32 and yielding labelled AEP on acid hydrolysis, was subjected to proteolysis by 'Pronase', trypsin, or the consecutive action of both. The material was heated at *p*H 4·5 at 100° for 10 min prior to suspension in the appropriate buffer for proteolysis. After incubation for 6 h, a large portion of the material had dissolved and the insoluble residue was removed by centrifugation. Acid hydrolysis (48 h in 6 N hydrochloric acid at 110°) of portions of the precipitate and supernatant, followed by electrophoresis and autoradiography, showed that the bulk of the AEP was still bound in the residue which was insoluble after proteolysis. The acid hydrolysate of this residue contained a large variety of amino-acids. AEP is thus associated with macromolecular complexes which resist hydrolysis by proteolytic enzymes.

The results described here suggest that the synthesis of the large molecules containing AEP is not likely to proceed by a pathway involving the incorporation of the free amino-acid pool AEP. The characteristic pattern of phosphorus uptake, and the resistance of the residual material to proteolysis, suggest that the lipids and the non-lipid complex containing AEP are a part of the structural material of the cell, possibly the cell membranes.

The nature of these complexes is being further investigated.

This work was started during a period of study leave spent in the Biochemistry Department, City of Hope Medical Center, Duarte, California. I thank the Center for its support and the provision of facilities, and Dr. Eugene Roberts for his advice.

I also thank the Fulbright Foundation for a travel grant to the United States.

Absence of Bile Salts in the Gastric Juice of a Crab

THE digestive juices of several decapod Crustacea have been shown to possess a low surface tension and emulsifying properties indicating the presence of surface-active compounds[1]. Earlier claims[2,3] of the presence of taurodeoxycholic acid in the gastric juice of the crab and the crayfish have not been supported by recent investigations[4] which have demonstrated some differences in the properties of the emulsifiers and those of bile salts.

The aim of the work recorded here was to establish by means of chromatographic and mass-spectrometric methods the presence or absence of bile salts in crab (*Cancer pagurus* L.) gastric juice.

Gastric juice was collected as described by Vonk[4] from freshly caught crabs and the juice was freeze-dried. The dried juice was extracted with hot ethanol and the alcohol extract was evaporated to dryness under reduced pressure. The residue (4·25 g corresponding to 85 ml. of fresh juice) was hydrolysed with 2 M methanolic potassium hydroxide at reflux temperature for 1 h. The hydrolysis mixture was diluted with water, acidified to *p*H 1 with hydrochloric acid and extracted first with ethyl ether and then with water-saturated *n*-butanol. Both extracts were washed with water until neutral and evaporated to dryness under reduced pressure. The weight of the residue of the ether extract was 150 mg and of the butanol extract 1·9 g. The residue of the ether extract was chromatographed on a 13·5 g column of hydrophobic 'Hyflo SuperCel' using phase system *F* 2 (ref. 5). Titration of the effluent showed the presence of four peaks with a combined weight of 48 mg. After methylation with diazomethane an aliquot of each peak was subjected to gas chromatography using *QF*-1 as stationary phase and under the conditions described by Sjövall[6]. The main components emerged from the column at much lower temperatures than do bile acid methyl esters and bile sterols. Mass-spectrometry of the material in the four peaks showed that two of these consisted of decanoic acid and *n*-dodecenoic acid respectively, whereas the material in the other two peaks could not be identified. No fragments typical of steroids or bile acids were found. The alcohol eluate of the column (91 mg) was found to consist mainly of cholesterol identified by melting point (147°–148°) with no depression on admixture of authentic cholesterol, and by thin-layer chromatography (benzene/ethyl acetate, 4 : 1, as moving phase).

The residue of the butanol extract was chromatographed on a 45-g column of hydrophobic 'Hyflo SuperCel' using phase system *D* (ref. 7). A single peak appearing shortly after the solvent front was obtained. This material (913 mg) was somewhat less polar than taurodeoxycholic acid both on paper and on thin-layer chromatography[8,9]. Neither from the remainder of the effluent nor from the alcohol eluate of the column could any material be isolated that on gas chromatography or mass-spectrometry showed properties of bile acids or steroids. The infra-red spectrum of the unknown material isolated from the butanol extract as described here showed peaks at 6·0 and 6·5μ, indicating the presence of amide groups. Due to the low volatility no mass-spectrum could be obtained. The unknown material was hydrolysed with 1 M sodium hydroxide in 50 per cent aqueous ethanol for 8 h in a sealed steel bomb at 120°. After dilution with water and acidification, the hydrolysis mixture was extracted with ether. The residue of the ether extract weighed 359 mg. Gas chromatography of an aliquot of the ether extract after methylation showed the presence of a number of compounds emerging from the column at temperatures lower than those required for bile acid methyl esters and bile sterols. Direct mass-spectrometric analysis of the gas chromatographic effluent[10] showed that the material in the ether extract consisted of a series of saturated and unsaturated straight-chain fatty acids with chain-lengths of 10–24 carbon atoms. The water phase of the hydrolysis mixture was passed through a 'Dowex 50-*X* 8' column (hydrogen form; 200 mm × 10 mm). The column was washed with water until the effluent was neutral and then with an additional 50 ml. of water. The effluent was evaporated to dryness under reduced pressure. Crystallization of the residue from methanol/water yielded 132 mg of taurine identified by thin-layer chromatography (ethanol/ammonia/water, 90 : 5 : 5, as moving phase[11]) and by formation of *N*-acetyltaurine with m.p. 190°, not depressed on admixture of authentic *N*-acetyltaurine. Thin-layer chromatography of the mother liquor showed that in addition to taurine another compound moving as sarcosine was present. The compound could be isolated by alcohol extraction of the residue of the mother liquor, followed by crystallization from water/acetone/methylene chloride. The crystals had m.p. 168° with no depression on admixture of authentic sarcosine.

The results of the present investigation show that no bile acids or bile alcohols are present in gastric juice of the crab. However, material possessing emulsifying properties can be isolated from an alcohol extract of dried gastric juice. This material, which has the same properties as that earlier investigated by Vonk, has been shown to consist of fatty acids, taurine and sarcosine.

Nuclear Magnetic Resonance of Phosphorus in Deoxythymidine Polynucleotides

NUCLEAR magnetic resonance signals from polynucleotides of thymidine-5′-phosphate have been investigated and the terminal monoester phosphate distinguished from the diester phosphate of the chain.

A mixture of 3′-O-acetylthymidine-5′-phosphate (1 m.mole) and thymidine-5′-phosphate (3 m.mole) was polymerized with di*cyclo*hexylcarbodiimide and the resulting mixture of polynucleotides was resolved on a DEAE-cellulose (carbonate) column using the method described by Khorana and Vizsolyi[1]. From the polymerization mixture, 26,500 optical density (OD) units at 267 mμ (1 m.mole of thymidine-5′-phosphate is equivalent to 9,600 OD units) were applied to the column and polynucleotides up to the dodecanucleotide were cleanly separated. Fractions were identified using paper chromatography with reference samples, prepared in the above manner by Khorana and Vizsolyi and characterized enzymatically by Dr. W. E. Razzell of Syntex Institute. Pooled fractions containing cyclic dinucleotide (3,300 OD units), linear dinucleotide (2,700 OD units), linear trinucleotide (2,600 OD units), linear tetranucleotide (2,300 OD units), and linear pentanucleotide (2,000 OD units) were evaporated to dryness and each dissolved in 0·5 ml. of methanol for the nuclear magnetic resonance measurements.

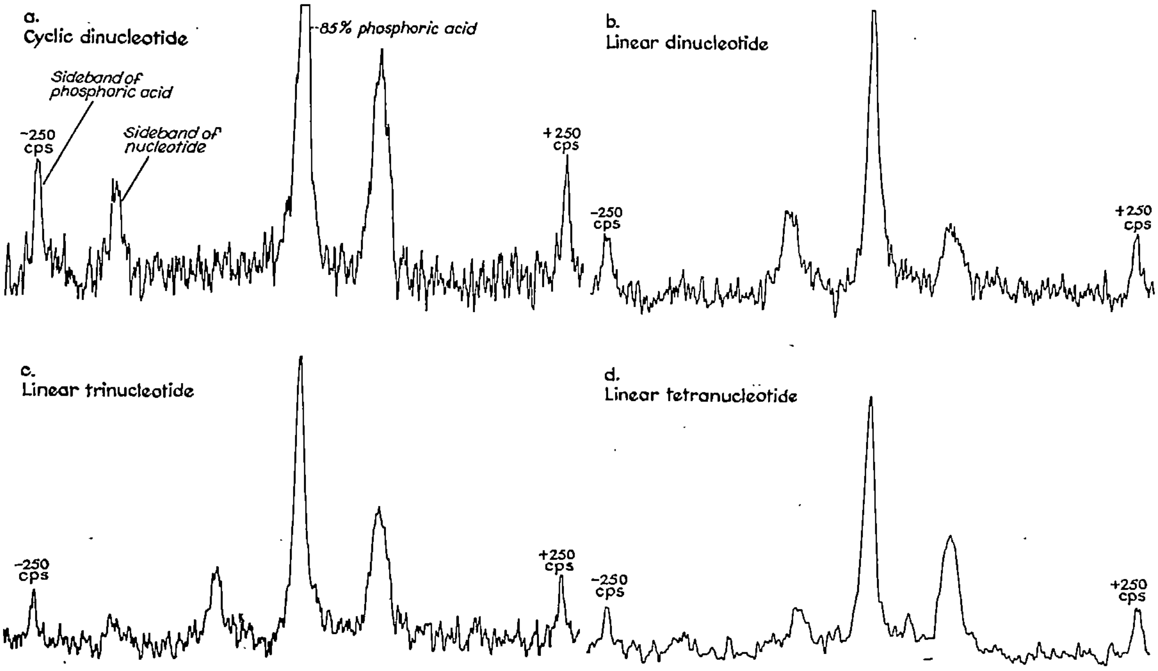

Fig. 1. Phosphorus nuclear magnetic resonance spectra taken at a sweep rate of 4 c/s/sec with a bandwidth of 0·5 c/s.

Nuclear magnetic resonance measurements on the phosphorus nucleus were made in a Varian spectrometer operating at 40·5 Mc/s. Chemical shifts were measured by the use of sidebands[2] with 85 per cent phosphoric acid as an external reference. The observed line width was of the order of 20 c/s. One can determine the number of nucleotides in short chains by the intensity ratio of the monoester to diester lines (Fig. 1). The chemical shifts of the monoester and diester lines are given in Table 1. Jones and Katritzky[4] have found the chemical shift of the phosphorus in trimethyl phosphate to be +2·0 p.p.m. in methanol and +2·7 p.p.m. in water. In the tetramethylammonium salt of adenosine triphosphate, Cohn and Hughes[5] find the chemical shift of α, β and γ phosphorus nuclei to be +11·2, +22·5 and +8·06 p.p.m. respectively at *p*H 7·0.

Table 1

Compound	Chemical shift (±0·1 p.p.m.) Monoester	Diester
Cyclic dinucleotide	—	+1·82
Linear dinucleotide	−1·90	+1·80
Linear trinucleotide	−1·90	+1·90
Linear tetranucleotide	−1·73	+1·93
Linear pentanucleotide	N.O.*	+2·00

*N.O., not observed because of poor signal to noise.

The phosphorus chemical shifts of the 5′-mononucleotides of DNA (100 mg of ammonium salt dissolved in 0·5 ml. of water) were also measured with 85 per cent phosphoric acid as an external standard and found to differ significantly. The purines, deoxyadenylate (−2·84±0·07 p.p.m.) and deoxyguanylate (−3·13±0·07 p.p.m.), were observed at higher fields than the pyrimidines, deoxythymidylate (−3·35±0·07 p.p.m.) and deoxycytidylate (−3·65±0·07 p.p.m.). If this difference in phosphorus chemical shift of the four nucleotides persists in the polynucleotides, it could provide a means of end-group analysis for short chains. To explore this further, oligonucleotides derived from the other three bases and mixed polynucleotides will be examined with more efficient signal-extracting techniques.

We thank Mr. Eugene Pier, of Varian Associates, for his assistance, and Dr. J. G. Moffatt, of Syntex Institute, for his advice on the synthesis of these oligonucleotides. The work was supported by grants from the U.S. National Institutes of Neurological Diseases and Blindness (grant *NB*–04270), National Institutes of Health *Linc* Computer Evaluation grant *FR*–00151–01, and from National Aeronautics and Space Administration grant *NsG* 81–60.

PHYSIOLOGY

Vitamin-binding Capacity of Experimentally Injured Liver

There are variable results on the therapeutic effects of B-complex vitamins given during experimentally induced liver injury[1–4]. Such results could be due to differences in vitamin binding by the injured liver. Because of the availability of sensitive and specific microbiological techniques for assay of tissue vitamin-levels[5], the work recorded here was undertaken. With these techniques, a more reliable assessment of the vitamin-binding capacity of the normal, necrotic and regenerating rat liver could be made.

Sprague–Dawley rats weighing 220–350 g were housed in individual cages and fed a standard diet of 'Purina Lab Chow' and water *ad lib.* To induce hepatic injury, rats were given 0·2 ml. of carbon tetrachloride (CCl_4)/100 g body-weight intragastrically via a polyethylene catheter; saline was administered in the same manner to control animals. Litter mates were pretreated daily for 5 days with glucose and water, or a mixture of B-complex vitamins intramuscularly; medication was continued until the animals were killed. The vitamin-treated animals received a mixture containing 50 mg thiamine, 10 μg cyanocobalamin (vitamin B_{12}), 1·0 mg folic acid, 50 mg nicotinic acid, 5·0 mg vitamin B_6, and 5·0 mg calcium pantothenate; these vitamin-levels saturated all tissues

The liver was removed from decapitated rats 12, 24, 36, 40, 48, 72, 96 and 120 h after they received CCl_4; and simultaneously from litter-mate control animals. After removal, the liver was perfused and rinsed with cold saline to remove adhering tissue and fluids; a section was removed for histology. The individual liver was homogenized in a blender with water, lyophilized to dryness, and stored at − 15° C. Liver sections obtained for histological study were fixed in formalin; paraffin sections of 7–8μ thickness were stained with hæmatoxylin and eosin. Nitrogen content of specimens, determined with a Coleman nitrogen analyser, served as a reference standard for the level of parenchymatous tissue. The vitamin content of the liver was assayed as described[5]. Because folinic acid is metabolically interrelated with folic acid[5], its assay in liver tissue was included even though it was not present in the vitamin supplement.

Vitamin titres were expressed as concentration per mg dried tissue, since differences between the nitrogen content of the liver of control animals and CCl_4-treated animals at the various phases of liver injury and regeneration were not significant. Histological examination was normal in both saline and vitamin-treated controls. Necrosis and inflammation involving one-third of the hepatic lobule were noted 24 h after receipt of CCl_4. Regeneration, as reflected in liver cell mitoses, was characteristic 48–96 h after receipt of CCl_4 (ref. 6); complete restoration of normal architecture was noted at 120 h.

Table 1 shows the mean vitamin titres obtained in liver tissue; deviations in each group of 4 or 8 animals was less than 10 per cent. Administration of vitamins to control animals caused no significant changes in thiamine, nicotinic acid, and vitamin B_6-complex titres; and increase was noted in folic acid (140 per cent), folinic acid (130 per cent), vitamin B_{12} (380 per cent), and a decrease in pantothenic acid (43 per cent).

* Vitamin titres in mμg/mg; vitamin B_{12} values in μμg/mg

In animals not receiving vitamins, CCl_4-induced necrosis was associated with a significant decrease in thiamine (50 per cent), folic acid (90 per cent), folinic acid (90 per cent), vitamin B_6-complex (40 per cent), and pantothenic acid (80 per cent). During the early phases of liver injury, no significant changes occurred in the levels of nicotinic acid and vitamin B_{12}. Pretreatment with vitamin supplements had a variable effect on rats with CCl_4-induced liver necrosis: it increased nicotinic acid and vitamin B_{12} titres above those seen with vitamin supplementation alone; prevented a decrease in thiamine; minimized reduction in folic acid, folinic acid, vitamin B_6-complex, and unexpectedly lowered pantothenic acid to or below the titres seen in animals not receiving vitamins.

After inducing liver necrosis in animals not receiving vitamins, the ensuing regeneration was associated with a slow return of the normal tissue vitamin titres; in most instances, low tissue-levels persisted 120 h after receipt of CCl_4-vitamin therapy enhanced restoration to normal levels.

Results of this work show that supplemental thiamine, nicotinic acid, and vitamin B_6 do not significantly raise hepatic tissue-levels of these vitamins in normal animals, but there is a significant increase in folic acid, folinic acid, and vitamin B_{12} following vitamin B_{12} and folic acid administration; this effect persisted after supplementation was discontinued. The latter result may be due to the greater tissue-binding capacity by the liver for these vitamins.

Despite receipt of pantothenic acid, there was a reduction in hepatic tissue-level of this vitamin in both normal animals and in animals following CCl_4-induced liver injury.

It seems that increased catalytic activities resulting from administered vitamins increase coenzyme *A* and pantothenic acid turnover. The lowering of folic and folinic acids during the regenerative phase may be attributed to their participation in forming nucleic acids for new cell syntheses[5].

B-complex vitamins given to normal animals caused an increase in tissue vitamin B_{12}, folic acid and folinic acid, and no significant alteration in thiamine, nicotinic acid or vitamin B_6-complex. This indicates that normal rat liver is not fully saturated with vitamin B_{12}, folic or folinic acid. The necrotic liver had diminished vitamin-levels, indicating a decreased vitamin binding by the necrotic liver. Supplemental vitamins hastened restoration to normal levels during the regenerative phases—a time when vitamin-binding capacity was probably also returning.

These results suggest an inverse relationship between some vitamins, especially vitamin B_{12} and pantothenic acid. It has been shown that increase in hepatic pantothenic acid is induced by a vitamin B_{12} deficiency; the reverse was also true[7,8].

‡ Munz (ref. 8) found a single pigment with λ_{max} at 520 mμ and based on vitamin A_2.

tested for pigment homogeneity by the method of partial bleaching[2]. The results are listed in Table 1.

One striking feature seen in these results is that absorption maxima (λ_{max}) are situated, with one exception, at 523 ± 3 and at 534 ± 2 mμ. Prior to the work recorded here, the vitamin A_2-based pigments of only 15 species of fishes had been adequately characterized; if, however, these results are considered together with those presented here, it may be seen that pigments apparently occur in groups at certain 'preferred' positions in the spectrum[3]. As Fig. 1 shows, these are centred at 511·5, 523·5, 534 and 543 mμ. It may be noted that the vitamin A_2-based pigments of Amphibia fall into the group centred at 523·5 mμ (ref. 4).

This observation raises two interesting possibilities. (*a*) One possibility is that the molecular structures of visual pigments do not permit continuous variations of λ_{max}. Thus a visual pigment molecule might be envisaged in which the protein moiety can influence the λ_{max} in a series of steps due to the addition of certain units analogous to double bonds in a polyene chain (it being assumed that the isomeric configuration of the chromophore is the same in all instances). From this point of view, the fish is 'presented' with a series of pigments of fixed λ_{max} from which it must 'choose' one to suit its own peculiar requirements.

(*b*) The other possibility is that while there may be no reason why pigments should not continuously vary their λ_{max} throughout the spectrum, the 'preferred' positions have been gradually evolved by unrelated species in order to accommodate certain common visual requirements.

At present, it is not permissible to attempt to distinguish between these two possibilities, although the existence of an 'aberrant' pigment with λ_{max} at 529 mμ in Fig. 1 (this is the well-established pigment of *Notemigonus crysoleucas boscii*[1] in Table 1) lends slight favour to the second, suggesting that pigments of intermediate λ_{max} are structurally possible.

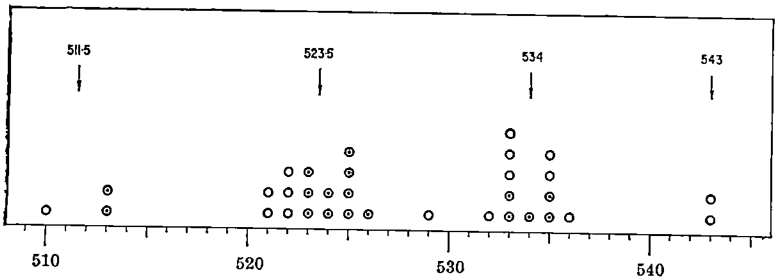

Fig. 1. Distribution of vitamin A_2-based pigments in fishes. λ_{max} are derived from Table 1 and refs. 4–8. The pigment with λ_{max} = 533 mμ of *Alburnus* (ref. 9) is regarded as paired and that of *Tinca* (ref. 2) as single. ⊙, single pigments; ○, pigments paired with corresponding ones based on vitamin A_1

The pairing of vitamin A_2-based pigments with others based on vitamin A_1 (in half the species of Table 1) and its probable function will be discussed elsewhere[10].

PHARMACOLOGY

Blood Salicylate during Pregnancy

In the course of investigating the effects of aspirin on pregnancy in the rabbit and rat, we have observed a difference in the free salicylate blood concentrations in pregnant and non-pregnant animals. Such a difference has been reported previously by Hartiala *et al.*[1] following oral administration of salicylamide to rabbits. Their work showed that concentrations of free salicylamide in the portal blood were much lower in pregnant than in non-pregnant animals, and that there were also small differences in the concentrations of the glucuronide conjugate of salicylamide.

In our experiments aspirin was given as an aqueous solution of the sodium salt adjusted to *p*H 7·0 at a dose of 120 mg/kg. Female rabbits in late pregnancy and non-pregnant controls received a dose volume of 1 ml./kg body-weight introduced into the mouth through a blunt needle. The animals were restrained in stocks, and blood samples collected into heparinized tubes by puncture of the marginal ear vein at various times up to 6 h after dosing. Female rats on day 19–23 of pregnancy and non-pregnant controls received a dose volume of 0·1 ml./kg body-weight introduced into the stomach by intubation. At each time-interval three different rats in each group were anæsthetized by ether inhalation and blood collected by cardiac puncture into a heparinized syringe. The free salicylate concentrations in the samples of whole blood from rabbits and rats were estimated by Trinder's method[2]. The values obtained from three rabbit experiments and from two rats experiments are presented in Table 1.

These results clearly indicate that the concentrations of free salicylate in whole blood are smaller in the pregnant than in the non-pregnant groups in both rabbits and rats. Statistical analysis shows that the mean free salicylate concentrations are significantly less in the pregnant groups in experiment 2 ($P < 0·05$) and experiments 4 and 5 ($P < 0·001$). The differences in experiments 1 and 3 taken alone are not statistically significant, but in all cases the mean values are smaller in the pregnant groups. In rabbits the relative difference in concentrations was greater with increase in time after dosing. For example, at 0·75 h the salicylate concentration in the pregnant

Table 1. FREE SALICYLATE CONCENTRATIONS (MG/100 ML.) IN WHOLE BLOOD OF PREGNANT AND NON-PREGNANT ANIMALS AFTER ORAL ADMINISTRATION OF ASPIRIN (120 MG/KG BODY-WEIGHT)

Groups of individual values are given followed by the mean value in parentheses

		Not		27·0, 21·5, 24·0 (24·2)	22·8, 20·9, 21·1 (21·6)	20·3, 18·9, 18·3 (19·2)	16·5, 15·9, 17·5 (16·6)
	5	Pregnant	19–23	21·7, 22·2, 18·4, 15·2 (19·4)	21·6, 16·7, 17·4, 16·1 (18·0)	17·7, 17·5, 15·5, 12·6 (15·8)	15·4, 13·0 16·1, 12·8 (14·3)
		Not		24·7, 31·1, 24·3, 21·9 (25·5)	21·7, 24·3, 20·8, 18·7 (21·4)	17·2, 22·6, 17·8, 20·3 (19·5)	18·3, 19·7, 17·7, 15·6 (17·8)

groups was on average 96 per cent of the controls, while at 6 h the average value had fallen to 49 per cent of the controls. This would indicate a shorter biological half-life for free salicylate in the pregnant animals than in the non-pregnant controls. In the rats, however, this effect was not apparent.

These observations suggest that the rate of metabolism and/or elimination of salicylate is more rapid in pregnancy. Booth and Gillette[3] have found that some steroid hormones affect the rates of drug metabolism so that changes in maternal hormones during pregnancy could explain the above findings. Another possible explanation would be accumulation of the drug by the fœtus; but if this were the case the drug must be stored selectively by the fœtal tissues because we have found that the salicylate concentrations in fœtal blood are about three-quarters of the maternal concentrations at various times after a dose of aspirin (120 mg/kg) to rabbit and rat.

We thank Dr. M. R. Gurd for his advice.

Stimulant Action of Barium on the Adrenal Medulla

BARIUM has been reported to release catecholamines from the adrenal gland in intact animals, and this action has been attributed to its setting up discharges in the splanchnic nerves[1]. A re-examination of the action of barium seemed to be called for in the light of more recent evidence that calcium, a closely related alkali earth, is intimately involved in the secretory process within the adrenal chromaffin cells. This evidence has suggested that the chemical transmitter liberated by the splanchnic nerves, acetylcholine, stimulates the chromaffin cells to secrete by increasing the permeability of their membranes so that there is an inward movement of calcium. In this view the appearance of an excess of calcium ions at some site in the chromaffin cell provides the immediate physiological stimulus for the release of the stored catecholamines[2–4].

We have examined the action of barium in acutely denervated cats' adrenal glands perfused through their arteries with Locke's solution, as previously described[2]. The perfusate escaping from the adrenal vein was assayed for catecholamines by bioassay[2], or by the photofluorometric ferricyanide method[5,6].

When barium was added to the perfusion medium in a concentration of 5 mM, the rate of catecholamine release increased greatly in every experiment. The increase was commonly more than 100-fold, for example, from 60 ng/min to 14·4 μg/min. Similar effects were obtained when the perfusion medium contained hexamethonium in a concentration (5×10^{-4} g/ml.) sufficient to block indirect actions through the splanchnic nerves which, although severed, were still present in the acutely denervated preparation. The stimulant effect of barium must therefore be attributed to some direct action on the chromaffin cells.

Unlike acetylcholine (or excess potassium), the stimulant action of which is abolished by removing calcium from the extracellular environment[2], barium continued to exert strong actions when given during perfusion with calcium-free 'Locke's solution'; and, indeed, its action persisted when the gland was perfused for 40 min or longer with a calcium-free 'Locke's solution' containing 3 mM EDTA as the disodium salt. This stimulant action of barium in the calcium-deprived gland mimics the action of calcium given in similar circumstances[2], and, like the corresponding effect of reintroducing calcium to the medium[3], was strongly inhibited by magnesium. Barium thus seems to be able to activate the 'secretory mechanism' just as does calcium. But barium has clearly some additional action which is not shared by calcium, for, as described here, it stimulates secretion when added during perfusion with Locke's solution, which contains 2 mM calcium. This is not true of calcium. The addition of excess calcium during perfusion with Locke's solution has little or no effect on secretion : calcium stimulates secretion only when the chromaffin cells are rendered unduly permeable to it either by a preceding period of calcium-deprivation or by exposure to acetylcholine or excess potassium[2,3]. Barium, however, appears to gain access to the 'secretory mechanism' without such aids. Since its hydrated ion radius is somewhat larger than that of calcium[7] it seems unlikely that barium is reaching this critical site simply by penetrating 'pores' in the chromaffin cell membrane more easily than calcium does. It seems necessary to suppose that barium has some action on the cell membrane which facilitates its own entry (and perhaps the entry of extracellular calcium). One possibility might be that barium promotes entry of sodium and by thus depolarizing the chromaffin cell membrane increases its permeability. Excess potassium, for example, is known to increase uptake of calcium in the adrenal medulla[8], and the effect of barium on the adrenal gland is reminiscent of that of calcium given along with a depolarizing concentration of potassium[3]. But against this possibility we have evidence that barium continues to act powerfully when added during perfusion with a sodium-free Locke's solution (Fig. 1). Further evidence that depolarization is not important for barium's action came from experiments in which barium was first added to Locke's solution to produce a sustained secretory response and then excess calcium was added while barium was still present. We argued that if barium did indeed owe its effect to some depolarizing action then the addition of excess calcium during exposure to barium should increase secretion as it does during exposure to excess potassium[3]. Excess calcium, however, had the opposite effect in these experiments and inhibited the barium-evoked secretion. This observation directed our attention to the possibility that barium might be acting to alter permeability by exchanging with the calcium bound to the membrane. We have earlier presented evidence that permeability of the chromaffin cells is increased when calcium is removed from their membranes by perfusion with a calcium-free medium[2,3]—and have suggested that the physiological secretagogue, acetylcholine, may increase the permeability of the chromaffin cell by displacing or prizing off this critical calcium fraction in its membrane[9]. It is all the more attractive to suppose that barium, which is more closely related in its chemical properties to calcium than is acetylcholine, is acting in a similar way and displaces membrane calcium by competition. This would imply that the replacement of calcium by barium renders the chromaffin cell membranes more permeable to these ions. Further evidence of antagonism between barium and calcium came from experiments in which brief secretory responses to barium were evoked at regular intervals either in Locke's solution or sodium-free Locke's solution, and where excess calcium was added along with the barium on alternate tests. It can be seen from Fig. 1 that increasing the calcium concentration inhibited the stimulant effect of barium on catecholamine secretion. Since the effects of calcium on secretion are excitatory whenever calcium is able to traverse the cell membrane, its inhibitory effect in this experiment indicates an action at an earlier stage and supports the idea that the two ions are competing for some membrane binding site.

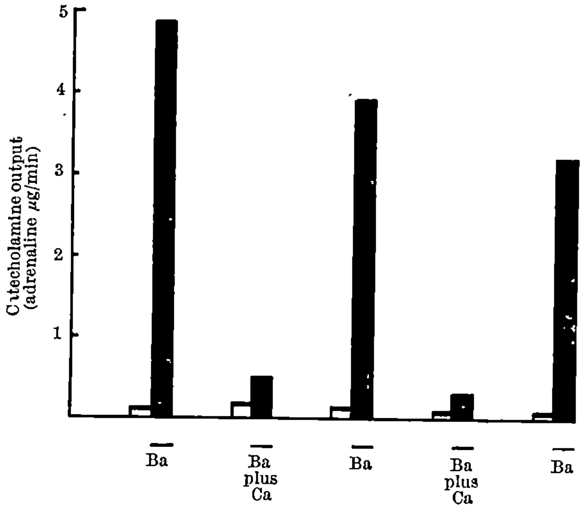

Fig. 1. The stimulant effect of barium on catecholamine secretion and its antagonism by calcium. The five successive pairs of responses were obtained at intervals of 14 min from a cat's adrenal gland perfused with sodium-free Locke's solution containing 2 mM calcium and hexamethonium 5×10^{-4} g/ml.: the tonicity of the solution was maintained by sucrose. The black columns indicate the secretory responses on adding barium (5 mM) alone or barium (5 mM) along with calcium (6 mM) for 2 min: the open columns indicate the control rates of catecholamine secretion in the 2 min preceding each test

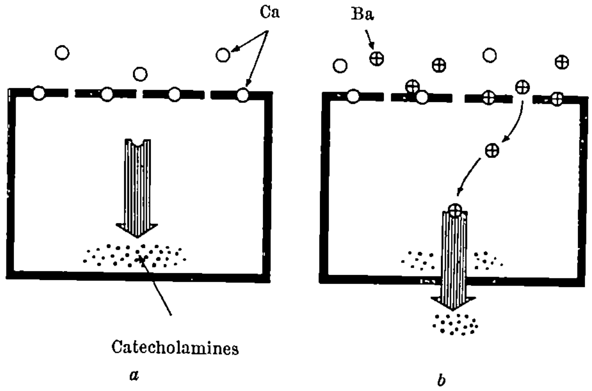

Fig. 2. A model of the suggested mechanism of action of barium on the adrenal chromaffin cells. In (*a*) the extracellular fluid contains a normal amount of calcium ions (○). The cell membrane is shown saturated with calcium, the function of which is to maintain a relatively impermeable state to ions including calcium itself. This is indicated by the small diameter of the 'pores' in the membrane. In (*b*) barium (⊕) has been added. It is depicted competing with calcium for the membrane sites of binding. Where it succeeds in displacing calcium the permeability of the membrane increases—as indicated by the enlarged pores—and barium (or calcium) enters the cell to activate the 'secretory mechanism' and induce extrusion of catecholamines. For simplicity, the 'pores' (channels of entry of calcium or barium, etc.) are shown distinct from the sites of calcium binding. This is not intended to imply that they are separate. The same comment applies to the site of barium (or calcium) entry and catecholamine extrusion

In summary, then, we suggest that barium acts on the chromaffin cell membrane to displace calcium, and that the barium–membrane complex is more permeable than the calcium–membrane complex; that this allows barium to traverse the cell membrane; and finally, that barium, once inside the cell, mimics the action of the normal secretagogue, calcium, and sets in motion the apparatus for catecholamine extrusion. These events are depicted in diagrammatic form in Fig. 2, which is based on a scheme presented at the second International Pharmacological Meeting in Prague in August 1963 to illustrate the supposed mechanism of action of acetylcholine[9].

In addition to barium, we have tested other alkali earths and various divalent ions. Strontium (2 mM) was almost indistinguishable from calcium in its effects on the adrenal gland. Magnesium (2–80 mM) did not itself evoke secretion in any of our experiments and antagonized secretory responses to other alkali earths, acetylcholine and potassium. Cobalt, manganese, nickel and zinc (each in a concentration of 2 mM) were without stimulant effect when added during perfusion with calcium-free Locke's solution and did not restore the responsiveness of the gland to acetylcholine. This spectrum of activity may possibly offer a clue to the nature of the unknown 'calcium-dependent' (or 'calcinergic') process involved in catecholamine extrusion.

Finally, we find it of great interest that our analysis of the effect of barium has led us independently to a mechanism of action on the chromaffin cell which resembles that advanced to explain its well-known stimulant action on smooth muscle[10]. We see in this a further extension of the already remarkable parallelism between the processes of 'stimulus-secretion coupling' in glands and 'excitation-contraction coupling' in muscles to which we have already directed attention[2-4].

Anomalous Reactions of the Rat to Ganglion Blocking Agents

In work which will be reported elsewhere it was found that certain extracts of the solanaceous plant *Cestrum parqui* caused a pronounced and prolonged elevation of the blood pressure of the anæsthetized rat. Since this reaction did not occur in the pithed animal, attempts were made to block the pressor effect at the autonomic ganglia. When hexamethonium failed to block the effects of *C. parqui* extracts it was decided to examine the effects of ganglion blocking agents *per se* in the rat.

Male albino rats of an inbred line originating from the Wistar strain and weighing 210–245 g were anæsthetized by intraperitoneal injection of urethane or intravenous injection of pentobarbitone sodium. Blood pressure was recorded from the left common carotid artery. The right common carotid artery was cleared and made available for clamping at intervals for 30-sec periods. Intravenous injections were made into the tail veins and washed in with 0·9 per cent saline. The doses which follow refer to amounts of base in each case, the substances used being hexamethonium (as the bromide, iodide or tartrate), pempidine tartrate, mecamylamine hydrochloride and 1-noradrenaline base.

Initially, hexamethonium was injected intramuscularly in a dose of 10 mg/kg, this being the dose used by Kärki[1] to stabilize the blood pressure and sensitize the animal to catecholamines. This produced a slight fall in blood pressure, but was without effect on the rise resulting from clamping of the right carotid artery. In subsequent experiments, intravenous hexamethonium in doses ranging from 1 to 10 mg/kg caused a marked blood-pressure fall, but whether or not an additional 5 or 10 mg/kg has been given intramuscularly or subcutaneously, there was never complete suppression of the pressor response to carotid clamping. This response, although markedly diminished during the first minute or two after intravenous injection, rapidly returned to its previous level. Subsequent repetitive dosage with hexamethonium intravenously had less and less blocking effect on the response, and after 3 or 4 doses of 10 mg/kg the response was markedly enhanced. This pattern continued with further doses, the animals usually dying after a total of 70–80 mg/kg had been administered over a period of 1·5–2 h.

Similarly, pempidine intravenously in doses ranging from 0·1 mg/kg to 5 mg/kg, and mecamylamine intravenously in doses of 0·5–5 mg/kg never completely blocked the pressor response to carotid clamping. With each drug, repetitive dosage at the 5-mg/kg level eventually enhanced the response.

The sensitizing effect of doses of hexamethonium 'too small to influence ganglionic transmission' in the rat submitted to carotid occlusion and noradrenaline injections has been reported by Sultan Mawji and Lockett[2]. The very large doses used in the present experiments, as well as enhancing the carotid reflex, also enhanced the response to injected noradrenaline. Furthermore, hexamethonium itself in some circumstances produced a marked pressor response. This was observed in the pithed rat preparation, after several doses of noradrenaline and three or four successive doses of hexamethonium 10 mg/kg. Afterwards, similar injections of hexamethonium caused a blood-pressure rise comparable in height and duration with the effect of 50 ng of noradrenaline. Injection of saline controls eliminated the possibility of the pressor effect being due to venous stagnation of earlier doses of noradrenaline.

It is of interest to note that examples of quaternary, tertiary and secondary amine ganglion blocking drugs were unable to block the pressor response to carotid occlusion in the rat, and that in fact all three agents in high dosage enhanced the response. Of the procedures used, only pithing the animals completely obliterated the pressor response.

PATHOLOGY

Resistance against Carcinomas of the Skin induced by Dimethylbenzanthracene (DMBA) in Mice of the Strain XVII/*Bln*

Past investigations in many laboratories concerning the antigenicity of experimental tumours have revealed that almost all the sarcomas induced by carcinogenic hydrocarbons contain specific antigens. For this reason a certain pretreatment of isologous recipients with these tumours can produce resistance against cell inocula of the tumour originally taken for immunization. Using this test system specific antigens were demonstrated in sarcomas which were induced by administration of methylcholanthrene[1-7], benzpyrene[5,8,9], dibenzpyrene[6], dibenzanthracene[10], and dimethylbenzanthracene[11].

Dependent on the mode of application the same substances are capable of producing carcinomas. Those tumours develop if the carcinogen acts on tissue of epithelial origin.

The demonstration of host resistance against grafts of the induced carcinomas would mean that the development of specific antigens is not only a characteristic of the sarcomas, that is, of tumours of mesodermal tissue origin, but also of tumours which arise from epithelial tissue under influence of the carcinogen.

First evidence for a tumour-specific immunizing capacity of epithelial tumours was obtained by Prehn[12], who has shown that methylcholanthrene-induced breast tumours (adenoacanthomas) of the *BALB/cAn* strain were antigenic in isologous hosts.

In this communication experiments on the induction of resistance against isologous cell inocula of DMBA-induced carcinomas of the skin are described.

Experimental animals were female mice of the strain XVII/*Bln*. For the purpose of tumour induction an acetone solution containing 0·01 per cent DMBA was prepared. Twice a week for a period of 10 weeks one group of mice (about 3 months old) was treated with the carcinogen-containing solution. Using a glass capillary to each mouse 3 drops of the solution were given to the dorsal region of the skin. The animals received a total amount of 120γ DMBA per mouse. The two tumours tested developed after latencies of 202 (DMBA 592) and of 267 (DMBA 788) days. Histologically they have been identified as keratinizing squamous epithelium carcin-

† Tumour material of the second generation of transplanting.
‡ Number of resistant animals over the total number inoculated.

omas. Because of the slow growth of the first transplant generations the immunization experiments were performed after 2–5 generations of transplanting the tumours in isologous hosts. Contamination of the primary tumour with bacteria was eliminated by suspending the cells in penicillin (100 I.U./ml.) and streptomycin (100 μg/ml.) containing saline solution following trypsination of the material.

According to previous experiments[7], isologous recipients were immunized by subcutaneous injections of the X-irradiated (14,500 r. *in vitro*) tumour suspensions prepared in a glass homogenizer. The animals received two injections in doses of 0·25 ml. per mouse at an interval of 14 days. The tumour material was diluted 1 : 4 in phosphate-buffered physiological saline solution. One day after the last immunizing injection a certain number of living cells was injected in the contralateral subcutaneous region of the mice to test the induced resistance. The cell suspension used for challenge was prepared by trypsination (0·15 per cent solution) of the tumour tissue. After vital staining of the cell suspension with trypan blue the dose required was adjusted. Control animals were mice of the same age and sex without prior immunization. The growth of the tumour implants was examined at weekly intervals.

The results obtained 25, 32 and 39 days after challenge injection are summarized in Table 1. The number of resistant animals in each group is presented over the total number inoculated. In the first experiment, in which DMBA carcinoma 592 was tested, all the animals pretreated were found to be resistant against this tumour if 6 × 10^5 cells were given subcutaneously. Eight animals in this group were immunized by a subcutaneous injection of 1·6 × 10^5 living tumour cells which did not lead to tumour formation. Six control mice developed tumours.

In the second experiment X-irradiated tissue suspensions of the carcinoma 788 were used for pretreatment. This tumour apparently induces a weaker resistance in the recipients although the immunization method used was the same as for carcinoma 592. 25 days after challenge inoculation (3 × 10^5 cells) only 13 of 30 animals in the experimental group were resistant. The number of resistant animals decreased to 5 mice 39 days after challenge injection and thereafter remained constant for an observation period of 90 days. In one animal of 30 control mice the tumour implant did not grow.

The final results of both experiments, presented as percentages of resistant animals in the experimental series in comparison with those in the controls, indicate that in mice a state of relative resistance against isologous cell inocula of carcinogen-induced carcinomas of the skin can be produced. The results of 65, 60 and 48 per cent resistant animals 25, 32 and 39 days after challenge injection in the test group as compared with 3 per cent in the control group are statistically significant.

From these experiments and considering Prehn's experiments[12], the conclusion can be drawn that tumour-specific antigenicity is not only a characteristic of carcinogen-induced sarcomas but also of carcinomas induced by carcinogenic hydrocarbons.

Susceptibility of Syrian Hamsters to Induction of Fibrosarcomas with a Single Injection of 3,4,9,10-Dibenzpyrene

THE carcinogenic activity of polycyclic hydrocarbons administered subcutaneously to hamsters was first described by Gye and Foulds[1]. Later, Halberstaedter[2], Crabb[3], and Lutz *et al.*[4] reported the sarcomagenic activity of other polycyclic hydrocarbons in hamsters. These investigators were primarily interested in the question of transplantability and metastases and used multiple injections for tumour production.

The experiments reported here were designed to determine the susceptibility of the hamster to a single subcutaneous dose of 3,4,9,10-dibenzpyrene (3,4,9,10-DBP). For 3,4,9,10-DBP the range was 2–0·25 mg/hamster. The carcinogen was dissolved in tri-*n*-caprylin ('Trioctanoin') at different concentrations such that the desired dose was contained in 0·4 ml.

Five groups of male hamsters weighing 55–75 g were randomly assigned to treatment and control groups, and were injected subcutaneously at the nape of the neck to determine the susceptibility and the dose necessary to induce tumours in a substantial proportion of the hamsters. At the highest dose of 2 mg/hamster, four animals died before the appearance of the first tumour.

Microscopically, the sections revealed typical fibrosarcomas of the subcutis which were fairly uniform in their histological pattern. The tumours were classified as typical spindle-cell sarcomas with closely packed spindle-shaped tumour cells. Solid masses of cells alternating with large and small whorls and interlacing bundles of fibrous connective tissue were observed. The tumour cells ranged in size and varied in shape from blunt to narrow

Table 1. Incidence of Subcutaneous Tumours in Male Syrian Hamsters given a Single Subcutaneous Injection of 3,4,9,10-Dibenzpyrene

Table 2. Subcutaneous Tumour Production in Syrian Hamsters induced with Single Injection of 1·0 mg 3,4,9,10-Dibenzpyrene, Hamster

Exp. No.	Effective No. of animals	Sex	No. of tumours per week and time (in weeks) 6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	No. of tumours	Tumour incidence (%)	Mean latency period (weeks)	Carcinogenic index
1 and 3	157	♀		5	6	19	40	32	23	18	4	5	4						1						157	100	11·0	130
2 and 4	139	♂			6	15	17	37	23	16	11	5	4	3	2										138	99	11·6	123

spindles. Mitoses were common, and occasional giant cells were present.

The incidence of tumours, mean latency period and carcinogenic index are recorded in Table 1. The percentage incidence is the number of tumours divided by the number of hamsters inoculated times 100. The mean latency periods were computed by multiplying the number of tumours each week by the time weeks after injection and dividing the sum by the total number of tumours. The carcinogenic indices, a value suggested by Iball[5], were determined by the formula $P/T \times 100$, in which P is the percentage of hamsters developing tumours, and T the average latent period of the experimental group in days.

It is evident from the data that 3,4,9,10-DBP is sarcomagenic for the hamster. The results also indicate that the tumour incidence and carcinogenic index decreased and the latency period increased as the dose decreased. Similar findings in mice were obtained for benzpyrene, dibenzanthracene and for methylcholanthrene[6–8]. As this was a pilot investigation to determine the susceptibility of the hamster, only a small number of animals was used in each group, but since the completion of this experiment an additional 169 female and 151 male hamsters have been injected subcutaneously with a single injection of 3,4,9,10-DBP at a dose-level of 1 mg/hamster. Twelve female and 13 male hamsters died without tumours during the course of the experiment.

The results in Table 2 show that the incidence of tumours, mean latency period and carcinogenic indices were similar for both male and female hamsters.

With the knowledge that the hamster can be utilized for the experimental induction of fibrosarcomas, detailed investigations are now in progress to gain some insight into the biological characteristics of the hamster fibrosarcoma resulting from a single subcutaneous injection of 3,4,9,10-dibenzpyrene.

Distribution of Intravenously Administered Saccharated Iron Oxide in the Popliteal Lymph Node of the Rabbit

Labelled thoracic duct lymphocytes transfused into host rats have been shown to migrate across the walls of the post-capillary venules of the lymph node, through the cortex into the medullary lymph sinuses[1,2]. In the present investigation, the fate of non-cellular particles in the lymph node of rabbits has been examined using intravenous

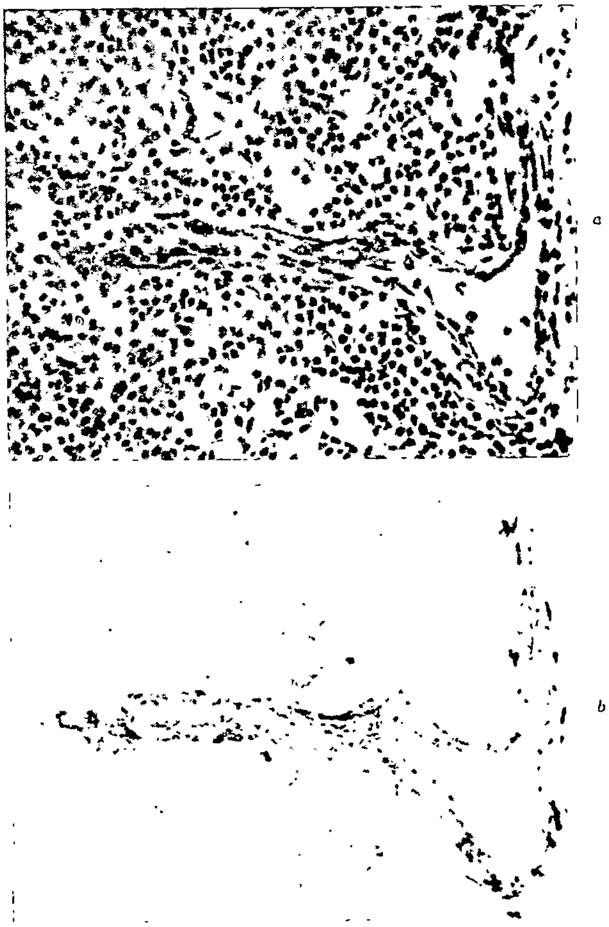

Fig. 1. Cortex of popliteal lymph node of rabbit after 20 days' intravenous 'Ferrivenin' administered as in text. *a* and *b* are of the same section stained with Prussian blue-nuclear fast red. By selective colour filtering *a* shows a venule with numerous intramural lymphocytes, while *b* demonstrates iron aggregates in the wall of the same vessel. Sections cut at 3μ ($\times c.$ 300)

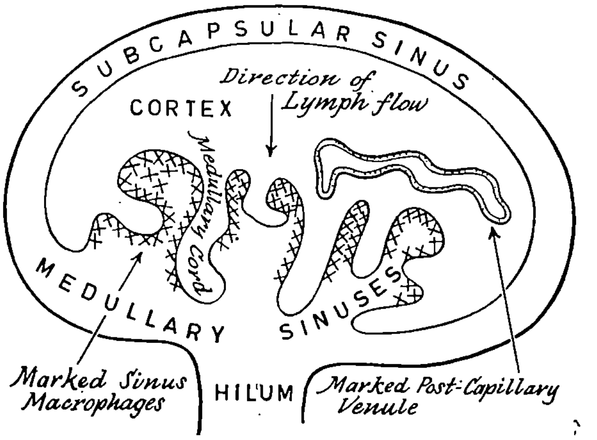

Fig. 2

saccharated iron oxide ('Ferrivenin', Benger) as the marker.

The marginal ear vein of adult rabbits of both sexes was injected with 1 ml. of 'Ferrivenin' daily for 1–20 days. One animal was killed each day, 24 h after its last injection, and popliteal lymph nodes were removed. Tissues were fixed in 10 per cent formolsaline (buffered with calcium carbonate) for 48 h and embedded in paraffin. Sections were cut at 3μ, stained by the Prussian blue reaction and counterstained by nuclear fast red[3].

Blue granules were found in the cytoplasm of medullary sinus macrophages after only one injection of 'Ferrivenin'. In the lymphatic cortex the few granules present were in the walls of venules. These vessels were considered to be analogous to the post-capillary venules in the lymph node of the rat, because of the frequent presence of lymphocytes in their walls (Fig. 1*a*). The venular Prussian blue marking increased progressively with subsequent injections and was intense on the twentieth day (Fig. 1*b*).

The combination of marking in cortical venules and medullary sinuses (Fig. 2) raises the possibility that saccharated iron oxide particles traverse the cortical venular walls and are carried by the lymph flow into the medulla, to be ingested by macrophages. The exact position of these particles in the wall of the venules will have to be investigated by electron microscopy.

* No blood sample taken.

ALVING *et al.*[1] have shown that primaquine-sensitive erythrocytes are deficient in glucose-6-phosphate dehydrogenase (G-6-PD) activity and a similar abnormality has also been found in *fava*-sensitive erythrocytes[2]. Consequent on their diminished G-6-PD activity, such cells have an unstable reduced glutathione-level (GSH) when exposed to various oxidizing agents[3,4]. Estimations of GSH stability are defined more clearly when glucose is added to the test system[5]. Under these conditions, little reduction in the GSH-level occurs when either *fava*-sensitive or normal erythrocytes are incubated at 37° C for 24 h, whereas a significant decrease, limited to the *fava*-sensitive cells, is found after incubation for a further 2 h at 37° C with acetylphenylhydrazine (APH). This final post-incubation GSH-level has been used to distinguish *fava*-sensitive from normal erythrocytes[5].

Beutler[6] has suggested that specimens for such tests might be stored at 4° C in acid-citrate dextrose (ACD) since during storage the G-6-PD activity and GSH-level and its stability in both *fava*-sensitive and normal erythrocytes remain unchanged for up to 30 days[7]. In addition the ACD would provide adequate glucose for the GSH stability test.

Preliminary examination by us of blood stored in ACD showed, however, an excessive loss of enzyme activity, while blood stored for transfusion purposes, also in ACD, gave suspiciously low GSH-levels even after as short a period as 7 days.

For estimations of G-6-PD activity and GSH stability in *fava*-sensitive and normal subjects, 7-ml. aliquots of blood were added to 2 ml. ACD of varying *p*H. G-6-PD activity was estimated by the method of Marks[8] and GSH by the method of Thompson and Watson[9], and its stability by a modification of the technique of Szeinberg *et al.*[5].

Using these techniques, the optimum *p*H of the ACD for G-6-PD and GSH stability was found to be 7·6 (Table 1), the same as that found for enzyme activity in heparinized blood using glycylglycine buffer of varying *p*H. Presumably the unsatisfactory results obtained in our preliminary experiments were due to partial deterioration of the enzyme with an associated drop in GSH stability, while the difference between the optimum *p*H range of 8–9 found by Marks *et al.* and that now reported may result from the purified material used in their system. All subsequent experiments were performed, therefore, using ACD, the *p*H of which had been adjusted to 7·6.

Despite correction of the *p*H of the ACD, the G-6-PD activity declined during storage. In the *fava*-sensitive cells the initial level was very low, none being detected after a week, whereas in the normal cells the initial level was high, 87 per cent of the activity remaining after one week (Table 2). Closer examination of the early storage period showed that after three days the level in the sensitive cells was negligible while in the normal cells it remained at about 90 per cent of the original value (Table 3). In contrast the GSH-level and its stability, although lower in the sensitive cells, were unaffected by storage of the samples of blood at 4° C in ACD at pH 7·6 for up to two weeks. During the third week the GSH stability of the normal cells fell, the final post-incubation value reaching the low, but relatively constant, level found in the sensitive cells (Table 2). Clearly ACD is satisfactory as an anticoagulant for field studies only if its pH is corrected to 7·6. Although storage of the blood under optimal conditions maintains the GSH-level and its stability for up to two weeks, the sample should be examined at once to determine its full G-6-PD activity. As the decline in G-6-PD activity is approximately linear the results of tests performed during the first 48 h may be corrected to indicate the original level. Later, owing to the rapidity of the decline in activity, results are less reliable so that *fava*-sensitive and normal subjects might be confused.

Differences of Bone Marrow Cells in Sheep and Man

Authors working on bone marrow of sheep have generally considered the cells sufficiently similar to those in man to disregard the necessity of their closer morphological examination. However, recent examinations of normal cells have disclosed differences which should not be neglected, particularly when changes of the bone marrow due to pathological conditions are to be examined. The detailed results are being published in monograph form, with comprehensive colour illustrations of all the cell types[1], and the following account summarizes the differences between (the cells of) sheep and man.

Using human material as a yardstick, the first impression gained of smears from sheep is apart from differences in shapes and sizes, a less brilliant display of colours, giving a duller and technically almost unsatisfactory picture. Differences between certain cells are less pronounced, making identification more difficult. The cells differ from their better known human counterparts mainly by the following characteristics.

In the erythrocytic series, the cells are smaller, due to less abundant cytoplasm, and develop into erythrocytes of an average diameter of only 4·5μ. The cytoplasm is more basophilic, which is particularly evident in the more mature stages where normoblasts show only a narrow rim of bluish cytoplasm around the nucleus. After denucleation, young erythrocytes are still bluish-grey, and only fully mature erythrocytes become more acidophilic, yet noticeably less so than in man. The failure of the erythocytes to stain a brighter pink contributes significantly to the duller appearance of the preparation. This cannot be improved by staining at a more acid pH as this would render the colour of the nuclei unsatisfactory.

In the neutrophilic series the cytoplasm becomes, with maturation, chromophobic rather than acidophilic. While it is distinctly blue in the youngest cells, it becomes less intensely stained with maturation and is pale blue or almost unstained at the metamyelocyte stage. In band cells it is even less stained, and in segmented cells, usually unstained, otherwise very pale pink. An outstanding feature of the neutrophilic series is the difficulty of demonstrating the characteristic granules. In segmented neutrophils small granules can usually be shown by certain conventional hæmatological dyes, in a narrow pH range, and a few granules are occasionally seen in band cells, but not in still younger cells. However, the presence of these granules, which are smaller than in man, can be demonstrated as far back as the myelocyte stage, by certain fat stains and the peroxidase reaction[2]. Segmented eosinophils rarely show two lobes, as usually seen in man, but three or four and occasionally more.

Monocytes are more difficult to recognize in sheep and may be confused with neutrophilic myelocytes, metamyelocytes or lymphocytes. The nucleus varies in shape from round to highly indented and resembles in texture that of a more mature metamyelocyte. The main difficulties are caused by the colour of the cytoplasm which is similar to that of neutrophilic myelocytes or metamyelocytes. The cytoplasm of the monocytes is less basophilic than in man, while that of the neutrophils is more basophilic than in the corresponding cells in man. Furthermore, the young neutrophils do not show granules. The 'ground-glass' appearance of the cytoplasm, usually characteristic for monocytes, is less pronounced, which makes differentiation from lymphocytes more difficult.

A myelogram of normal sheep based on 122 counts from 18 healthy animals, with an insignificant parasite burden[3], showed the proportions of erythrocytic and eosinophilic cells to be 60·8 and 8·76 per cent respectively, and thus several times higher than in man. The average granulocytic/erythrocytic ratio was 59·4 per cent and the average granulocytic maturation ratio 53·4 per cent. It is argued, however, that this form of calculation as practised in man, is not suitable for sheep. While in man granulocytes other than neutrophils amount to a relatively insignificant number, in sheep, with their larger proportion of eosinophils, such treatment of granulocytes as a uniform group would give valid results only if alterations of the eosinophils due to pathological conditions closely followed alterations of the neutrophils. As this is unlikely, neutrophils and eosinophils have been separated and the following average ratios have been found: neutrophilic/erythrocytic, 41·8 per cent; eosinophilic/erythrocytic, 16·37 per cent; neutrophilic/eosinophilic, 317·0 per cent; neutrophilic maturation, 49·2 per cent; eosinophilic maturation, 66·18 per cent.

These findings, representing the normal bone marrow of sheep, are now being used as a basis for studying alterations due to various pathological conditions; in the first place acute and chronic post-hæmorrhagic anæmia and helminthic anæmia.

High-potency Antihæmophilic Factor Concentrate prepared from Cryoglobulin Precipitate

INVESTIGATIONS made to determine the causes of loss of antihæmophilic factor (AHF) during the Blombäck process[1] for preparing AHF-rich fibrinogen from large volumes of plasma have revealed that when the starting material is frozen plasma instead of fresh plasma there is a presumed liability which can be converted to an advantage.

The well-known susceptibility of AHF to denaturation by heat, storage, freezing and thawing has led to attempts both in Sweden[1], and in the United States[2], to arrange for prompt processing of freshly collected plasma whenever possible. If large-scale production is contemplated, however, such a requirement is a distinct handicap, and so our efforts have been directed to maximizing the yield from frozen plasma.

In order to investigate the causes of poor final product activity after standard Blombäck processing, samples were taken at each step to determine where the largest losses were occurring. As previously reported[3], the 'starting material' was found to have on the average only 54 per cent of the activity of the mean of normal individuals, and this low level was attributed to the freezing, thawing, and storage involved. Essentially all the remaining activity was recovered in Cohn Fraction I, but the citrate–ethanol–glycine extraction used to obtain the Blombäck Fraction I–O regularly resulted in large and variable losses of AHF activity. Still further decreases occurred during sterile filtration and ultra-violet irradiation. These latter procedures are not necessary in Sweden and England, where it is possible to process small batches under sterile conditions. Our final product, at that time, when prepared as a 2 per cent solution, typically had only the same AHF activity as normal plasma. More recent lots have approximately twice as much AHF activity, but even though the protein concentration is about one-third that of plasma, this is clearly a far from ideal therapeutic material.

A recent review of this project revealed that the 'starting sample' for analysis had in each case been taken after a preliminary step. This step, 'Clarification', involved centrifuging the plasma which had been thawed at 10°–12° C, pooled, and re-cooled to 1°–2° C, in order to remove any materials which had failed to dissolve. When six new batches of approximately 1,000 l. each were studied, it was found that the samples taken before clarification (the cryoglobulin material dissolves on warming for assay) averaged 90 per cent AHF activity, whereas after clarification the average was only 46 per cent. It thus became apparent that storage losses were not so great as previously thought, but that almost half the plasma AHF was being discarded in the clarification residue. This finding should not have been a great surprise since one of us reported previously that undissolved cryoglobulins in plasma include large amounts of AHF[4]. Attention now turned to this material, a gelatinous paste, of which approximately 2 kg were obtained from a 1,000-l. plasma pool. On a wet weight basis, between 10 and 20 per cent assays as protein, thus representing only about 0·4 per cent of the original plasma proteins. However, about 20 per cent of the original plasma AHF (half the AHF lost during the clarification) can be recovered from this material. Therefore, on a protein basis, a 50-times concentration of AHF activity has been achieved with this step alone.

Table 1. CIRCULATING AHF RESPONSE TO FRACTION *PR* 2018 IN FOUR PATIENTS WITH SEVERE CLASSICAL HÆMOPHILIA

Patient	^{51}Cr—Det'd. Plasma volume (ml.)	Fraction transfused (mg.)	Post-transfusion AHF-level (%)	Calculated AHF activity of fraction (units/g)
T. T.	2,500	375	16·5	870
R. P.	2,300	750	40	945
J. G.	2,360	750	35	848
S. F.	2,100	750	30	638
				Average = 825

Subsequent studies have dealt with further purification and sterile filtration of this material to prepare a concentrate for clinical use. A report on the details of this process is in preparation. The final product at present studied in clinical trials has an activity of 825 units of AHF (1 unit = AHF activity in 1 ml. of normal human plasma) per gram of protein, as determined *in vivo* after transfusion into hæmophilic patients. Actually our *in vitro* determination gives approximately twice this value in the Pool and Robinson AHG assay[5] following dilution of 0·1 ml. of the fraction with 0·9 ml. of hæmophilic plasma prior to the adsorption step. At this time there is no way of telling whether the true activity is in the range of 1,650 units/g, and, for some reason, only half of it is recovered after transfusion, or whether the true activity is 825 units/g, and we have not yet solved the problems of *in vitro* assay of very high potency materials.

Table 1 gives the data on the four patients with severe classical hæmophilia who received this material after determination of their chromium-51 plasma volumes had been carried out. The result on patient R. P., who received 750 mg of material, shows that a solution which can be administered with a 50-ml. syringe is capable of raising the circulating level of such a patient to 40 per cent of normal.

IMMUNOLOGY

Specific Precocious Protective Action of Toxoids

THERE have been several reports of a specific precocious protective action, not involving antibody response, of tetanus toxoid against tetanus toxin[1-8]. Massive doses of tetanus toxoid injected into mice protected them against a few lethal doses of tetanus toxin injected at the same time, or shortly before, or shortly after. Diphtheria toxoid, given in doses comparable on a basis of antibody-combining power units, had no such protective effect against tetanus toxin[5,6]. Suggestions have been made that the protective action of tetanus toxoid may be connected with its ability to prevent the fixation of tetanus toxin by nervous tissue[7-9] and ganglioside[10].

We have tested whether other toxoids have a similar protective action against their homologous toxins. A number of toxins were titrated by injecting 0·5 ml. volumes of serial two-fold dilutions into control and toxoid-treated animals. Toxoid and toxin were injected in immediate succession intramuscularly in the same hind-limb. In the case of tetanus, toxoid and toxin were also injected intraperitoneally and intravenously. The toxins and toxoids (in crude form) were kindly supplied by Dr. R. O. Thomson of the Wellcome Research Laboratories. In each case, the largest practicable dose of toxoid was used, which was 0·5 ml. of the solutions as

provided by Dr. Thomson. Mice were used in all the experiments except those with diphtheria toxoid and toxin, where guinea pigs were used. The number of animals used for each dilution of toxin are shown in Table 1. Deaths were recorded for 7 days after the injection of toxin. All the animals that died did so within two days, except those injected with tetanus toxin, which died on all the days between the first and seventh day after injection.

The results of these experiments are shown in Table 1. The values given in column 9 were obtained by dividing the values in column 3 by the means of those in column 8; they are based on the assumptions that the toxin preparations used for making toxoid contained no toxoid before toxoiding and that homologous toxins and toxoids have the same molecular weights. *Cl. oedematiens* and diphtheria toxoids in the doses used had no protective effect; *Cl. welchii* Type *A* toxoid in the comparatively small dose used had a very doubtful protective effect; *Cl. welchii* Types *B*, *C* and *D* toxoids appear to have had specific protective effects greater than that of tetanus toxoid by several orders of magnitude. Column 5 shows that in some cases these conclusions are based on the survival of very few animals, and the values in column 9 must be regarded as qualitative rather than quantitative; nevertheless, we believe they support the conclusion that the specific precocious protective action of tetanus toxoid is not unique. Additional experiments showed that *Cl. welchii* Types *C* and *D* and diphtheria toxoids in the doses shown in Table 1 failed to protect against *Cl. welchii* Types *D* and *C* and tetanus toxins respectively.

This work was carried out under contract with U.S. Office of Naval Research (task 103–474).

Homotransplantation Antibodies detected by Mixed Agglutination with Cell Culture Monolayers

FORMATION of humoral antibodies as a result of tissue homotransplantation in mice was shown by the hæmagglutination technique introduced by Gorer[1,2]. Later, other serological methods such as lysis[3], cytotoxicity[4], leuko-agglutination[5], and complement fixation[6] have been used.

The purpose of this communication was to detect homotransplantation antibodies by means of the mixed agglutination technique on tissue culture monolayers[7–9].

The mice used in this work were purchased from Roscoe B. Jackson Laboratories. Full thickness skin grafts approximately 18 mm in diameter were exchanged between mice of *C3H/He* and *C57BL/6J* strains. In addition, some *C57BL* mice were grafted with skin of other mice of the same strain. The transplantation technique described by Hauschka[10] was followed; however, cleaning of the graft by dissection was omitted. The mice were bled from the retro-orbital plexus at various time-intervals and sera from the individual bleedings were tested.

Strain 929 '*L*' cell fibroblasts obtained originally from a *C3H* mouse by Earle[11] was used as the *in vitro* antigen. Eagle's minimum essential medium in Hanks' balanced salt solution (BSS) with antibiotics and 10 per cent calf serum was used for cell growth. Cell cultures which formed complete monolayers were used in the test.

The mixed agglutination test was performed in a similar way as described in a previous communication[9]. Cell cultures were washed three times with LH medium (0·5 per cent lactalbumin hydrolysate in BSS). The sera to be tested were inactivated for 30 min at 56° C. They were incubated with the cultures for 2·5 h at room temperature. Then the cultures were washed five times with LH medium and the indicator system was added. In order to prepare this, human blood group O erythrocytes were mixed with mouse anti-human erythrocyte serum. The resulting small agglutinates were washed and incubated with a rabbit antiserum against mouse serum. The red blood cells were washed again and prepared as a 0·25 per cent suspension.

Table 1 summarizes the results obtained from one experimental series. As is to be seen, all sera of *C57BL* mice transplanted with *C3H* skin acted on the '*L*' cells, which was to be expected, inasmuch as '*L*' cells are of *C3H* origin. The sera of *C57BL* mice grafted with skin of their own strain gave virtually negative results. Sera of *C3H* mice grafted with *C57BL* skin gave negative or

Table 1. MIXED AGGLUTINATION TEST WITH '*L*' CELL MONOLAYERS AND MOUSE SERA OBTAINED IN THE THIRD WEEK AFTER SKIN GRAFTING

	No. of sera with a titre of 1:					
	<10 and 10	30	90	270	810 and more	Total
C57BL grafted with *C3H* skin	0	0	1	2	9	12
C57BL grafted with *C57BL* skin	5	0	0	0	0	5
C3H grafted with *C57BL* skin	11	2	0	0	0	13

only weakly positive reactions. One could expect positive reactions of the latter sera on tissue cultures derived from *C57BL* mice; however, these experiments have not yet been performed.

It was our experience that antibodies could be detected as early as 9 days, and persisted at least 48 days after grafting. It was also found that re-transplantation of *C3H* skin on *C57BL* mice would result in an increased titre of the mixed agglutination test.

It is felt that the described procedure may be a very useful tool in detecting humoral antibodies accompanying homotransplantation. For convenience, an established cell line was used in this work; however, preliminary experiments indicated that primary cell cultures would give similar results. The titres of hæmagglutinating antibody reported by others may sometimes equal or even exceed those observed in this work; however, most of the antisera which have been tested by hæmagglutination were obtained by extensive immunization with erythrocytes, normal tissue or tumour tissue rather than by a skin graft.

It is hoped that the mixed agglutination technique may be useful in elucidating the mechanism of homograft rejection and in the delineation of transplantation antigens.

This work was supported in part by a grant from the National Foundation and by a Public Health Service fellowship 5 *F*1 *GM* 10,886-4 from the Division of General Medical Sciences.

RADIOBIOLOGY

Production by X-rays of Petite Colonies in Yeast and their Radiosensitivity

THE effect of X-rays on the viability of cytochrome a_3-deficient yeast cells, which form petite colonies, has previously been examined and compared with that of the wild type, which forms normal-sized, large colonies[1-5]. The reported results differ to a certain extent. Thus Moustacchi[3], O'Brien[5] and Gonzales and Barron[2] observed an increase in radiosensitivity of petite cells, while Raut and Simpson[1] and Wood[4] found no such difference. This discrepancy may be due to strain differences, to the use of either naturally occurring petite mutants or of colonies produced by chemical means, such as acriflavine or gentian violet, or to the use of cells not genetically related and, therefore, not directly comparable.

Production of petite colony formation by X-irradiation has also previously been reported[1,6], but with greatly differing results. Thus, at approximately identical X-ray doses, 100–150 kr., the yield of petite colonies among survivors in the experiments by Raut and Simpson[1] never exceeded 5 per cent while it reached 40 per cent in the work of Patrick *et al.*[6]. No attempts have been reported at increasing the yield of petite colonies by repeated irradiation of survivors nor has the sensitivity of radiation-produced petite cells been examined. The present work intends to fill this gap.

The yeast used was a diploid strain of Distillers Co., Ltd., baker's yeast, maintained as stock culture on wort-agar slopes. For the purpose of X-irradiation, the cells were grown in a synthetic medium[7]. The irradiation procedure was the same as previously described[8] at a dose rate of 8 kr./min. For aerobic irradiation, oxygen was bubbled through the cell suspension during irradiation.

Production of petite colonies. The number of petite colonies among survivors increased with increasing X-ray dose in an irregular manner, the highest yield being 25 per cent, after which it began to decrease to almost zero on further increasing the X-ray dose. The dose giving the highest yield of petite colonies, however, was not constant, varying in the present experiments between 32 and 96 kr. No explanation for this was found. If a single petite colony was streaked on wort-agar, the resulting colonies were a mixture of petite and large colonies. This indicates that a number of cells reverted to the parent type. A similar result was obtained when cells from a single colony were inoculated into liquid medium and plated on wort-agar after having grown to approximately 10^7 cells/ml. The percentage of re-appearing large colonies was variable in both cases, but, as a rule, did not exceed 30 per cent. No relation between X-ray dose, percentage of petite colonies and reversion to large type could be established.

In order to test the radiosensitivity of radiation-produced petite cells it was, therefore, necessary to obtain a strain of petite cells which breeds true. This was effected by repeated subculture and irradiation of successive (petite) survivors. The procedure was as follows:

(1) A yeast suspension, approximately 1×10^7 cells/ml., is irradiated with 32 kr. in oxygen and, suitably diluted, plated on wort-agar.

(2) A single petite colony of the survivors is inoculated into liquid synthetic medium and allowed to grow at 30° with aeration for about 18 h.

(3) 0·1 ml. of this culture, suitably diluted, is spread on a wort-agar plate.

(4) After 3–4 days' growth at 30°, a single petite colony is again subcultured in liquid medium, as (2).

(5) This suspension is irradiated with 64 kr. and plated for survivors.

Steps 2–5 were repeated five times and followed by two cycles in which the X-ray dose was doubled (128 kr.).

After 5–6 irradiations the number of large colonies which reappeared on the plates became decidedly less, the seventh and eighth cycle showing none. Subcultures from different colonies of the last cycle remained petite throughout, without further interposition of irradiation. The strain has now been maintained as 'petite colonies' for eighteen months.

Spectroscopic examination. Assessment of cytochrome content revealed absence of cytochrome a_3; cytochrome b appeared to be present only in traces while cytochrome c was richly present. The absence of cytochrome oxidase (a_3) is typical for petite yeast and agrees with the findings on chemically produced petite mutations[9,10].

Metabolism. The respiratory rate, measured manometrically, with glucose as substrate was very low ($Q_{O_2} = 1$–2 at 30°), while aerobic fermentation was almost as high as the anaerobic fermentation:

$$Q^{O_2}_{CO_2} = 145, \; Q^{N_2}_{CO_2} = 150$$

Radiosensitivity. No difference was found between the cells of large and petite strains. On plotting viability against X-ray dose (Fig. 1), the curves for both types of cells were almost identical, having the same initial slope followed by a short plateau, which is characteristic for this and other yeasts, individual variations falling within normal limits[8]. The oxygen-effect of irradiation in petite cells was equally not altered, the oxygen-enhancement ratio being approximately 2, as in the parent strain[8]. This latter point is in agreement with previous results by Moustacchi[3] and confirms her conclusion that the magnitude of the respiratory rate of a cell is not one of the factors which determines the oxygen-effect of irradiation. However, this does not entirely support her implied rejection of the theory put forward as the basis for the oxygen-effect[11], namely, that it is due to the irreversible reduction of an enzymatic cell component present during irradiation in the oxidized state. A similar view has previously been expressed by Tahmisian and Devine[12].

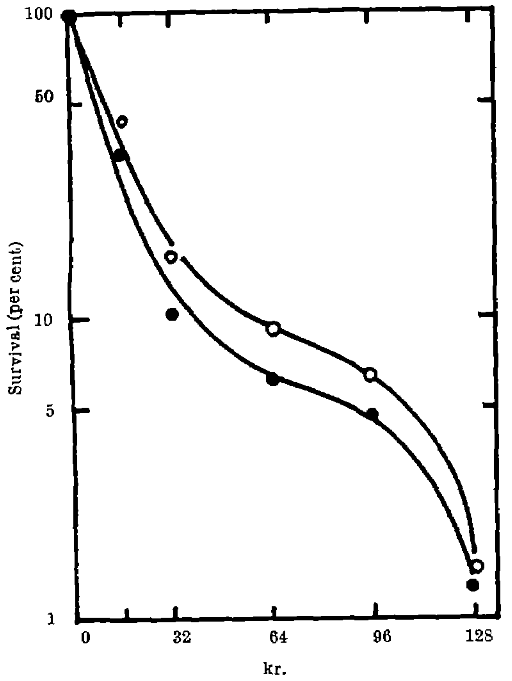

Fig. 1. Effect of X-rays on the survival of large, wild-type (●) and of petite (○) yeast

The experiments, finally, touch on the unresolved question, which may be of practical importance, namely, whether repeated irradiation of survivors may change their radiosensitivity and produce either more sensitive or more resistant cells. The former possibility appears, *a priori*, almost incapable of experimental verification except within narrow limits, because the more sensitive the cells might become the more easily they are rendered non-viable, thereby escaping the practical test. One case only has been reported[12] where a bacterium (*E. coli*[13]) showed a slightly increased susceptibility to radiation damage after repeated exposures to γ-irradiation, while two other *E. coli* strains, on the contrary, became more resistant. The technique used was to use massive inocula of irradiated cells for consecutive subcultures. The same procedure has been used in the work of *S. faecalis* and *E. coli* by Erdman *et al.*[14], who obtained a 1·2–1·9-fold increase in resistance after eight repetitive cycles. Further irradiation failed to raise the degree of resistance.

The results of the work recorded here indicate that the initially produced petite cells cannot be due to genetic difference of the two strains, because of the very high incidence (25 per cent) of petites and their facile reversion to the wild type. On repeated irradiation of petite survivors, however, the cells seem to have lost their ability of spontaneous reversion and to have gradually evolved into a genetically stable strain, indistinguishable from a true mutant. Although the changes involve the conversion of a fast-growing aerobic into a slow-growing anaerobic cell, the radiation sensitivity, nevertheless, remained unaltered.

Influence of Chronic Gamma-irradiation on the Yield of Chromosomal Aberrations in Rat Liver Cells

It has already been shown that radiation damage to chromosome is conserved for several months after an acute X-irradiation. Due to this, dividing of a dose into two fractions with a seven-day interval between them had the same effect as a single irradiation[1–4]. Similar results have been obtained by other authors[5,6]. Results of the induction of chromosome aberrations during chronic irradiation are presented here. Preliminary results have been published elsewhere[7].

Female albino rats weighing 160–180 g received from the Animal Farm of the U.S.S.R. Academy of Medical Sciences were exposed to 150 rads of cobalt-60 γ-rays under the following conditions: (1) acute irradiation; (2) chronic irradiation. All animals were placed at various distances from the source and irradiated concurrently for 24 h. Partial hepatectomy was carried out with the standard method[8] 24 h after irradiation. Animals were killed 30 h after the operation. In each animal, the number of cells with chromosome aberrations was assessed among 100 late anaphases and early telophases on slides stained by the Feulgen method and with light green. The same was performed on non-irradiated rats. The mitotic index in non-regenerating liver was determined in 6 normal rats and in 6 irradiated with 150 rads (26 rads/min). The number of mitoses among 100,000 cells was counted in each animal.

The percentage of cells with chromosomal aberrations diminishes with the dose-rate decrease (Table 1). This phenomenon may be caused by: (1) selective death of cells with chromosome aberrations during interphase; (2) death of such cells as a result of division; (3) restitution of chromosome damages. Interphase death of liver cells does not occur even after their exposure to much higher doses[9]. There are grounds for suggesting that interphase death of cells in mouse bone marrow and in intestinal crypts is not related to chromosome aberrations[3,10]. That is why the first hypothesis seems to be less probable. Let us assume that the percentage of cells with aberrations increased linearly. In the absence of cell division it would then reach $A_0 = 22{\cdot}4$ per cent (the

effect of acute irradiation without normal 'background') after accumulation of $D_{\max} = 150$ rads for T days. Let us also assume that the division of cells with and without chromosomal aberrations has equal probability. Then the increase in the number of cells with aberrations may be described by the equation:

$$\frac{dA}{dt} = k\frac{D_{\max}}{T}(I-A) - qA = k\frac{D_{\max}}{T} - \left(k\frac{D_{\max}}{T} + q\right)A$$

where q is the rate of cell division. When solved, this equation shows that the number of cells with aberrations at any time t after the onset of chronic irradiation is:

$$A_t = \frac{k}{k\frac{D_{\max}}{T} + q} \cdot \frac{D_{\max}}{T}\left(I - e^{-\left(k\frac{D_{\max}}{T} + q\right)t}\right)$$

In T days, that is, after accumulation of $D_{\max}$:

$$A_T = \frac{kD_{\max}}{kD_{\max} + qT}(I - e^{-kD_{\max} - qT}) =$$

$$\frac{I}{I + \frac{qT}{kD_{\max}}}(I - e^{-kD_{\max} - qT}) =$$

$$\frac{I}{I + 3.92\,qT}(I - 0.776e^{-qT})$$

since $A_0 = A_{T=0} = I - e^{-kD_{\max}}$; $A_0 = 0.224$;

$$e^{-kD_{\max}} = I - 0.224 = 0.776, \frac{I}{kD_{\max}} = 3.92.$$

A_T values can be determined in Table 1. While solving the equation for T values from 15 to 90 days, the average $\bar{q} = 0.0435$ is obtained. The mitotic indices in non-regenerating liver in normal and irradiated animals were 0·0058 and 0·0048 per cent, respectively. Taking into consideration diurnal changes in mitotic rhythm[11], let us assume that the mean index is 0·01 per cent and that the duration of mitosis is 30 min. Then $q = 0.0048$, that is, at least one order less than $\bar{q}$. Therefore, the data presented cannot be interpreted only by the elimination of cells with chromosome aberrations as a result of their division.

This conclusion is confirmed by the results of experiments in which hepatectomy has been carried out 3 months after a single irradiation (dose-rate, 26 rads/min) and 5·5 months after chronic irradiation (dose-rate 7×10^{-3} rad/min) with 150 rads (Table 1). If the decrease in the percentage of cells with chromosome aberrations were to be caused only by their division then the percentage of such cells in these experiments could be expected to be equal to that after chronic irradiation for 3 and 6 months. Actually it was respectively 3 and 10 times higher. Thus, in these cases, there is a conservation of chromosome damage after irradiation in agreement with earlier published data[1-5]. The observed decrease in the percentage of cells with chromosomal aberrations under conditions of chronic irradiation can be suggested to be caused, apart from elimination, by the restitution of chromosome injury during irradiation. Probably, the reparation of chromosome damage may take place during fraction γ-irradiation with small doses[6] which does not occur under neutron treatment[12].

About 60 per cent cells with aberrations have one acentric fragment (Table 2). One break in one chromosome results in one or two acentric fragments. Therefore, it is possible to assume that approximately 60 per cent of damaged cells have one break in one chromosome. The distribution of cells with one, two and more acentric fragments, with bridges, etc., did not significantly change at various irradiation times (Table 2). If the hypothesis on the restitution of chromosome damage were correct, then the results presented in Table 1 would suggest that reparation took place not only in cells with two injured chromosomes but in those with one damaged chromosome as well. A break of a chromosome seems to be a multi-hit process. It may be that all or none of the damaged chromosomes undergo recovery. Further experiments are required to check up on these hypotheses.

We thank Dr. V. Yu. Urbakh for his advice and help in the mathematical treatment of the data.

BIOLOGY

An Inhibitor of Adrenal Steroid 11β-Hydroxylase

Trans-1,4-*bis* (2-chlorobenzylaminomethyl) *cyclo*hexane dihydrochloride ('AY–9944')[1] has been shown to represent a novel class of cholesterol biosynthesis inhibitors which act by interfering with the enzymatic conversion of 7-dehydrocholesterol to cholesterol[2,3]. In laboratory animals, 'AY–9944' significantly depressed serum sterol-levels[4]. In view of its potential use as antihypercholesterolemic agent[5], we have studied the effects of this agent on adrenal steroid metabolism. The inhibition of 11β-hydroxylase by 'AY–9944' in rat adrenal homogenates is reported herewith.

The effect of 'AY–9944' on the conversion of progesterone, 11β-hydroxyprogesterone and 11-deoxycorticosterone to corticosterone by rat adrenal homogenates[6] was determined by the fluorometric method of Guillemenin *et al.*[7]. As indicated in Table 1, 'AY–9944' inhibited the conversion to corticosterone of both progesterone and 11-deoxycorticosterone without affecting that of 11β-hydroxyprogesterone respectively. Hence, in rat adrenal homogenates 'AY–9944' depresses 11β-hydroxylation without affecting 21-hydroxylation. The inhibitory action of the agent on 11β-hydroxylase was corroborated by measuring its effect on the conversion of 11-deoxycorticosterone-4-^{14}C to corticosterone-4-^{14}C by rat adrenal homogenates; at a final concentration of 1 × 10^{-4} M the inhibition was 60 per cent.

The effect of 'AY–9944' on 11β-hydroxylation was compared with that of 'SU–4885' ('Metopirone'), a known 11β-hydroxylase inhibitor[8] (Fig. 1). The concentration of 'AY–9944' sufficient to cause a 50 per cent inhibition of 11β-hydroxylation, that is, 6·6 × 10^{-5} M, was significantly lower than that of 'SU–4885', that is, 9·6 × 10^{-4} M.

Table 1. EFFECT OF 'AY-9944'* ON THE CONVERSION OF PROGESTERONE, 11-DEOXYCORTICOSTERONE AND 11β-HYDROXYPROGESTERONE TO CORTICOSTERONE BY RAT ADRENAL HOMOGENATES

Substrate	Inhibition of corticosterone formation (%)†
Progesterone	73

11β-Hydroxyprogesterone‡	2

* 1 × 10^{-4} M final concentration.
† Each value is the mean of three separate determinations.
‡ Final concentration, 1 × 10^{-3} M 'AY-9944'.

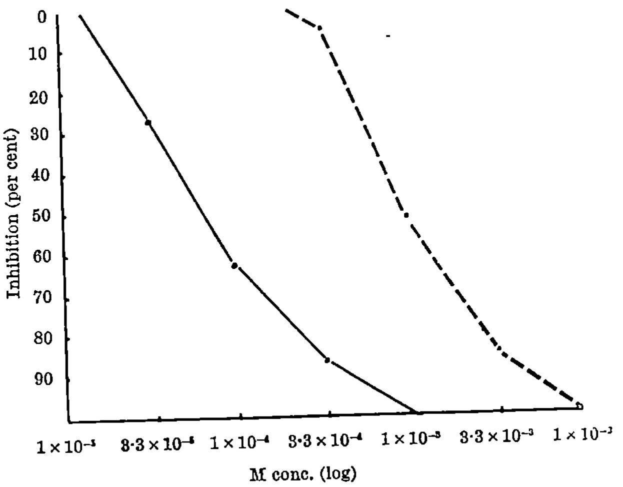

Fig. 1. Effects of 'AY-9944' (——) and 'SU-4885' (– – –) on the conversion of 11-deoxycorticosterone to corticosterone by rat adrenal homogenates

It is interesting to note that 11β-hydroxylase activity was not affected in adrenal homogenates obtained from rats given orally 10 μmole/kg of 'AY–9944'. In contrast, in liver homogenates obtained from the same animals the metabolism of 7-dehydrocholesterol, as measured by the method of Kandutsch[3,9], was completely blocked. The finding that, *in vivo*, 'AY–9944' does not affect rat adrenal 11β-hydroxylase parallels the experience with 'SU-4885' which, *in vivo*, was inactive in rats[10] and an effective 11β-hydroxylase inhibitor in dog[11] and man[8].

We thank Mrs. Sheila Gosselin for assistance and Dr. A. Marton of the Department of Pharmacology for the generous supply of adrenal tissue.

Variations in Flow of Blood within the Epididymis and Testis of the Sheep and Rat

THE total venous outflow from the testis and epididymis of conscious rams has been measured using the Fick principle with tritiated water as the dilution substance[1]. Because of their different functions the two organs might have quite different blood flows, and it cannot be assumed that each contributed blood to the total venous outflow in proportion to its weight. The technique of Sapirstein[2] has been used to determine the partition of blood between the testis and epididymis.

Twenty male rats (290–430 g) were anæsthetized with pentobarbitone sodium and given 5 μc. of 4-^{131}I-iodo-antipyrine into the jugular vein. Sapirstein's method depends on the ratio of organ content to body content of isotope becoming constant soon after injection. The ratio of the amount of iodine-131 in the testes and in the epididymides to that in the rest of the body was constant between 10 and 60 sec; the same was true for brain. In a second experiment, using 12 rats, the epididymides were divided into six portions that were intended to correspond with zones 1–6, as described by Reid and Cleland[3]. For each portion the ratio of its isotope content to that in the rest of the body was constant during the period 20–40 sec after injection, indicating that the technique was valid for the portions as well as for the whole epididymis. The variation in flow of blood between the parts is shown in Fig. 1. The flow was always highest in the first portion of the head of the epididymis with a smaller peak in the body portions 4 and 5.

Assuming a cardiac output for rats[2] of 20·5 ml./100 g/min, the flow of blood through the whole epididymis was 14 ml./100 g/min in both experiments and through the testis 21 ml./100 g/min in both experiments; the latter value is much higher than the 14 ml./100 g/min previously reported for testis[4]. The mean flow of blood through the epididymal fat pad was 8·8 ml./100 g/min in the first experiment and 3·8 ml./100 g/min in the second.

Sapirstein[5] later applied his technique to the human brain and head using external counting equipment. A similar technique has been applied to the sheep; one scintillation probe was directed at the head and one at the scrotum of four rams anæsthetized with pentobarbitone sodium and 100 μc. of ^{131}I-iodoantipyrine was injected intravenously. The concentration of iodine-131 in the brain became constant between about 60 and 90 sec and that in the testis between about 90 and 120 sec after injection. Four rams were therefore killed, 90 sec after isotope administration, by the rapid intravenous injection of saturated potassium chloride containing pentobarbitone sodium (10 g/100 ml.). The heart stopped within 10 sec. At the same time as the injection of the potassium chloride, the blood flow to the testes and epididymides was arrested by clamping the spermatic cords. The various organs were then dissected out, and portions weighed and counted.

Assuming a cardiac output for anæsthetized sheep of 11 ml./100 g/min[6–10], the blood flow through the testis was 11 ml./100 g/min and, unlike the rat, that through the epididymis as a whole, 11·4 ml./100 g/min, was similar. These values are close to those previously found[1] for the testis and epididymis together, using the Fick principle and tritiated water. The blood flow in eight sites in each testis was quite uniform. The blood flow in the epididymis was low in the first portions of the head, increasing to a peak in portions 8 and 9, just beyond where the head turns back on itself. There was a sharp decrease in flow in the last portion of the head and the first portion of the body of the epididymis, a slight increase in lower portions of the body and a further decrease in the tail (Fig. 1).

This pattern is different from that in the rat but the anatomical arrangement in the two species differs also[11]. The cells lining the duct of the first segment of the rat epididymis are tall and secretory, but they are low in the first portion of the ram epididymis, which corresponds to the efferent ducts of the rat. Taller cells are found in portions 3–8 of the ram epididymis. In both species, tall cells are also found in the distal parts of the body[3,12]. Thus the highest segmental blood flow in both species roughly coincides with the portions of the epididymis that have the tallest epithelial cells. It has also been shown that the incorporation of ^{32}P-phosphate into glycerylphosphorylcholine is higher in the head than in the tail of the epididymis of the rat[13], that the head of the epididymis has more alkaline phosphatase than the tail[14], and that absorption of dye from the lumen is greatest in the head of the epididymis[15].

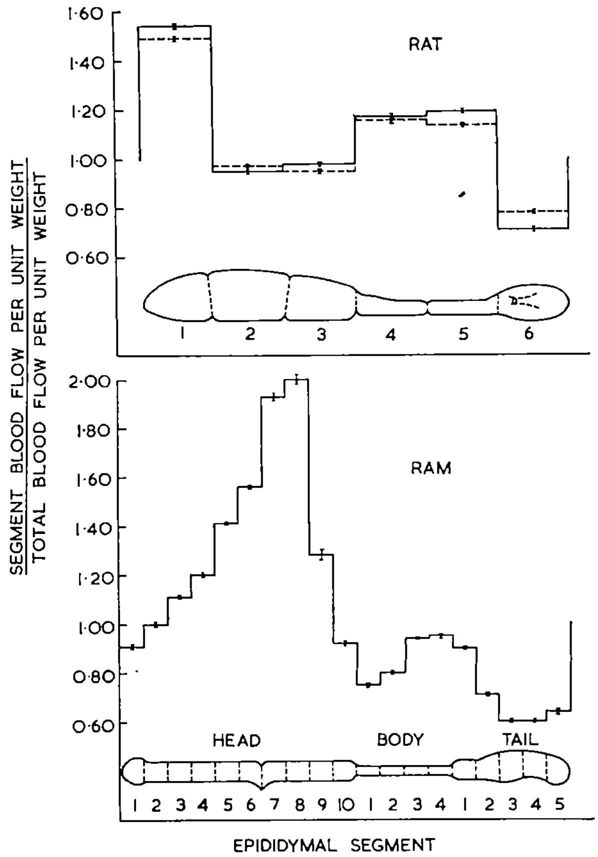

Fig. 1. Variations in blood flow in different parts of the epididymis of the rat and ram. Flow is expressed as the ratio of blood flow per unit weight in the segment to flow of blood per unit weight of the whole epididymis. For rat, estimates 20 sec (——) and 40 sec (– – –) after injection of isotope. Means for 24 rat and 7 ram epididymides with their standard errors are shown. Drawings of the epididymides are diagrammatic

It would, therefore, appear that the region of highest blood flow is also a region of high metabolic activity, but as we have noted that the venous blood from the head of the epididymis of the ram was more oxygenated than that from the tail, it is tempting to postulate that the high blood flow has some specific function other than supply of oxygen.

HEXAFLUOROBENZENE

AND 74 COMPOUNDS

These compounds are being made available world-wide for the first time, following the discovery by Imperial Smelting Corporation Ltd., and at the University of Birmingham, of a new and attractive synthetic route. They open up exciting possibilities in such fields as polymers, pharmaceuticals, dyestuffs and agricultural chemicals, where the presence of a fluorinated aromatic ring may lead to novel properties. Many companies and university research departments are taking experimental quantities of these fluorocarbon compounds and carrying out their own programmes of investigation.

Removal and Dissociation of Epithelial Cells from the Rodent Gastrointestinal Tract

WITH advances in the study of gastrointestinal physiology, knowledge of functions unique to the intact organ has accumulated. To facilitate investigations at a cellular level, attempts have been made to obtain a pure suspension of epithelial cells for *in vitro* investigations. In procedures so far reported, there is contamination of the cell suspension by mesenchymal elements[1-3]. Additionally, abundant flora in the postnatal gut has hampered cellular maintenance and study. The following method largely overcomes these difficulties and provides a reliable cell sample for *in vitro* biochemical, anatomical, and immunological analysis.

Male Sprague–Dawley rats weighing 100–200 g were used in this work. Seventy-two hours prior to death, neomycin (10 mg/30 ml.) is added to their drinking water. Forty-eight hours prior to death, all food is withheld with the final 24 h under complete oral restriction. Sixteen hours before death, each rat receives by gastric tube 24,000 units of 'Nystatin', 500 mg of streptomycin, and 200,000 units of procaine penicillin *G*. Our bacteriological investigations confirm the fact that this procedure reduces organisms to an extremely low level[4].

Of the methods available for dissociation of cells, trypsinization as described by Moscona is used[5,6]. Rats are anæsthetized with pentobarbital sodium, and the bowel is removed under aseptic conditions. The stomach and colon are removed *in toto*, but the small intestine is divided into two equal portions for ease in handling. To obtain a closed system, in which both wash and enzymatic solutions come in contact only with epithelial elements, lengths of vinyl tubing are inserted intraluminally at distal and proximal ends of the organ and tied into place. The epithelial surface is washed several times with room temperature calcium magnesium free (CMF) Tyrode's solution introduced through a syringe attached to the tubing. The bowel segment is then filled with fresh CMF Tyrode and incubated for 15 min at 37° C. This solution is discarded and replaced by 3 per cent trypsin/pancreatin (3 : 1) in CMF Tyrode and incubated again for 15 min at 37° C and pH 7·0 ± 0·10. Longer exposures to trypsin reduce cell viability to 50 per cent or less, and shorter exposure times reduce the cell yield considerably. During and after incubation, the bowel segment is mechanically agitated to facilitate cell removal. A medium composed of Eagle's solution, 10 per cent horse serum, glutamine, penicillin, streptomycin and vitamin A is then washed through one end of the organ as the cells are collected in a syringe at the opposite end. This suspension is adjusted to yield a 4 : 1 ratio of medium to trypsin and, afterwards, forced through a wire mesh of 0·086-millimetre pore size to disrupt cell clumps. Further dispersion is obtained by repeatedly forcing the suspension through a 14-gauge needle. The cells are washed twice with medium by centrifugation at 300g for 5 min and resuspended for counts and culturings. Cell yields have averaged 175 × 10^6 for the small intestine, 30 × 10^6 for the stomach, and 47 × 10^6 for the colon with viabilities of 76 per cent, 78 per cent, and 87 per cent, respectively, as determined by the nigrosin stain[7].

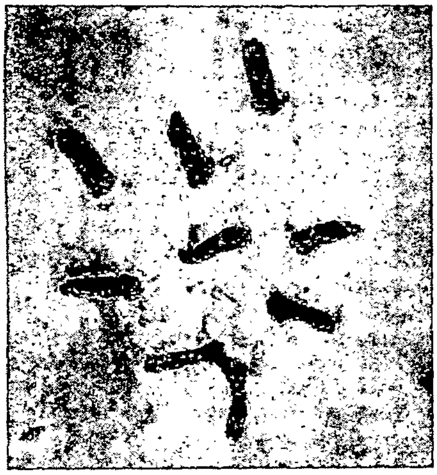

Fig. 1. Epithelial cells after removal from small intestine (× 565)

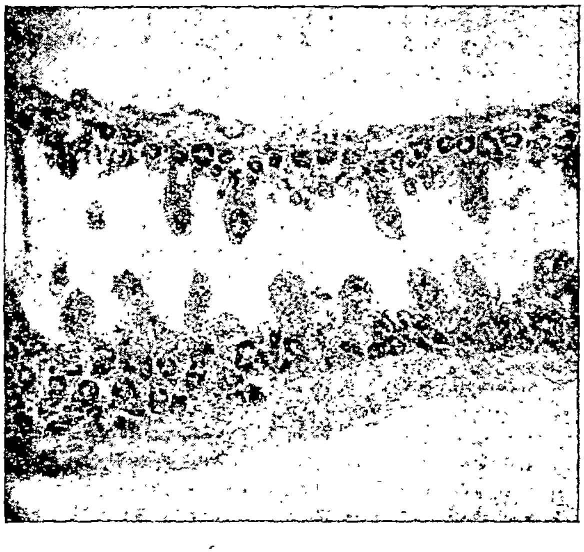

Fig. 2. Section of small intestine following trypsinization (× c. 94)

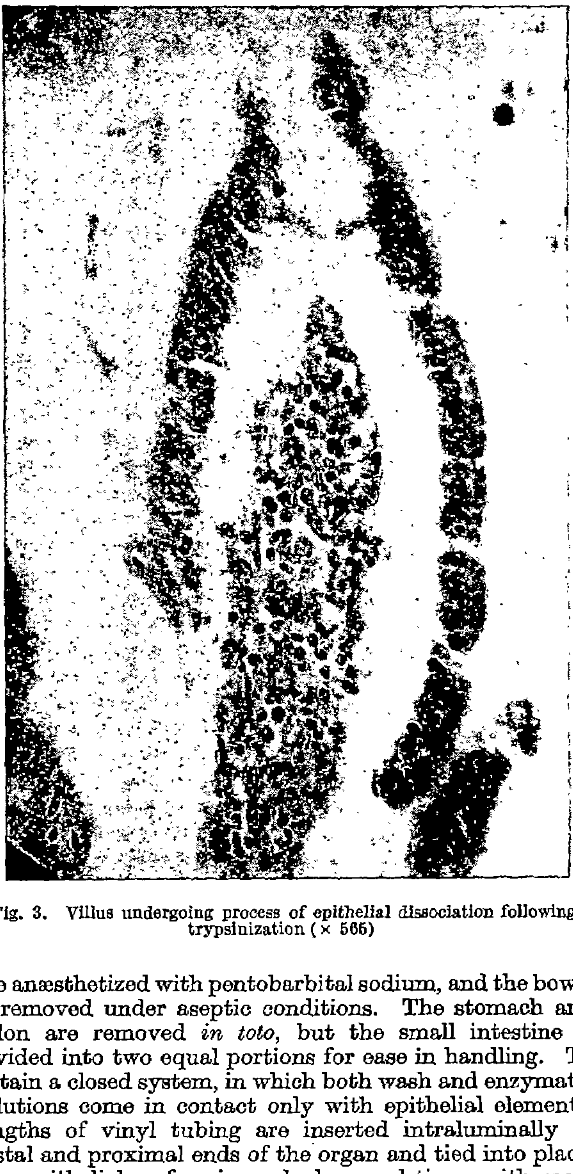

Fig. 3. Villus undergoing process of epithelial dissociation following trypsinization (× 566)

Smears of cell suspensions stained with azure-eosin show a collection of well-dispersed cells. Differential counts of these smears give an average of 81 per cent epithelial cells, 13 per cent lymphocytes and granulocytes, and 6 per cent bare nuclei. From the small intestine, two types of epithelial cell may be distinguished: a large columnar or sometimes slightly rounded cell with brush border and a smaller rounded form seen individually or within isolated crypts (Fig. 1). The stomach yields both dark staining chief cell types and large eosinophilic parietal cells. Cells from the colon are basophilic, varying in size and cytoplasmic content, and of ovoid or goblet shape. Following trypsinization, sections from all levels of the gut show a loss of epithelial cells with an apparently intact basement membrane (Figs. 2 and 3). It is of interest that a tryptic digest method similar to the one described has been used successfully to separate epithelial cells from other hollow organs such as aorta and Fallopian tubes[8,9].

Preliminary work done on gastrointestinal cells removed by trypsinization includes metabolic investigations and *in vitro* cultivation. A report of the characteristics of respiration of dissociated gastrointestinal epithelial cells will soon be forthcoming[10]. As yet a culture line has not been established, although small intestinal cells have been maintained in continuous culture for 3 weeks. An opportunity is now afforded for definitive investigation of metabolic processes peculiar to gastrointestinal epithelial cells.

We thank Mr. Warren Snyder for his assistance and Dr. A. Moscona for his advice. This work was supported by grant *CA* 04904 of the U.S. National Cancer Institute made to one of us (R. W. R.).

Growth Stasis and Tryptophan Deficiency in the Very Young Chicken

Considerable work has been reported concerning the consequences of underfeeding poultry and animals in the early stages of growth[1,2]. Quite typically, growth in terms of weight gain is markedly reduced, but some tissues of the animal, particularly the connective tissues, cartilage, etc., continue to develop[1]. Basal rations used to examine amino-acid requirements usually do little more than slow down growth or maturation rates. However, we have now found that for the chick, depending somewhat on the strain used, tryptophan-deficient diets fed to chicks weighing less than 80–100 g completely stopped gain in weight and all, or nearly all, visible signs of subsequent maturation. Therefore, it was of interest to observe whether prolonged tryptophan deficiency would affect subsequent maturation or physiological development. Reproduction (egg production) was chosen as a very sensitive indicator of successful maturation in the chicken.

Chicks were fed semi-purified diets of the type shown in Table 1. These basal diets contained adequate levels of all essential amino-acids and of all known nutrients, when compared to accepted standards[3], except tryptophan. Chicks were maintained in electrically heated brooders, with wire mesh floors, in air-conditioned rooms. Food and water were available *ad libitum*. After hatching, the chicks were fed a commercial 'starting' ration for 6–9 days, or until they weighed 90–100 g. The chicks were then distributed at random into groups of 10 chicks each and fed diet 3. Initially, quadruplicate groups received each treatment. By the third experimental day, significant differences were found between the tryptophan-supplemented and tryptophan-deficient groups. By the end of 21 days, it was noted that birds receiving the basal diet virtually had not grown at all. These chicks appeared grossly unchanged from a chick of 7–10 days of age; that is, no further development (feet enlargement, comb growth) had occurred. When fed a tryptophan-supplemented diet, growth immediately resumed. However, it was observed that once the chicks weighed 180 g or so, when they were fed the basal diet again their growth was not stopped, but continued at quite a slow rate (4–5 g per day rather than 14–17 g on the tryptophan-replete diet). In fact, a stair-stepping effect, achieved by stopping and starting growth by feeding alternately tryptophan-deficient and tryptophan-supplemented diets, could be demonstrated for chicks if they weighed less than the 180–200 g. So long as the birds were maintained on the basal diet and weighed less than 125 g, they did not grow appreciably, nor did any signs of partial maturation occur as is usually observed when chicks are deliberately starved or the level of total protein or total calories is drastically reduced.

Table 1. Tryptophan-deficient Diets

A longer term experiment was conducted to determine if chicks could be held for a greater time at the 100-g stage and to see if this period of growth stasis would adversely affect the maturation process. Pullets were used, because it was felt that normal egg production could be used as an index of satisfactory development and maturation. Twenty-five 'Hy-line' female chicks were fed the basal diet after being grown to a weight of 95 g (8 days) using a commercial chick-growing ration. As in the previous experiment, none of these chicks grew at all.

Table 2. EFFECT OF TRYPTOPHAN DEFICIENCY ON ONSET OF EGG PRODUCTION

	Control	Experimental
No. of hens	9	10
Days fed deficient diet	10	180
Weight at: day 204	2,080 g	111 g
day 397	—	2,130 g
Average No. of days to lay 10 eggs/hen	204	397
Net days after repletion for 10 eggs/hen	180	193

After 10 days, 10 pullets were fed the tryptophan-supplemented diet. They immediately began growing at a rate (14 g gain/day) similar to the rate observed in the first experiment. After 14 days, when they weighed 280 g, these birds were fed commercial rations and observed until they had produced 10 normal eggs each. This took an additional 180 days, 204 days after the experiment was started (the 9 surviving hens thus averaged 212 days of age when they had laid 10 eggs each).

During this time the remaining 14 pullets (1 had died of the remaining 15) were fed the tryptophan-deficient diet only. On the 204th experimental day these birds weighed, on the average, 111 g; they had thus gained some 16 g during this period. When fed the tryptophan-supplemented diet, they immediately began growing at the rate previously observed for the control group of chicks, about 14 g/day. After 14 days (the 218th experimental day) they weighed 302 g. At this time, 10 of the chicks were fed the commercial growing ration and four were returned to the basal diet. After 20 days, the chicks fed the basal diet had gained only 60 g, while the pullets receiving the commercial ration had gained 180 g. The 4 chicks fed this basal diet were then discarded, and the remainder were observed until they, too, had laid 10 eggs each. This took 193 days (the 397th experimental day), on the average, after they had been permitted to resume growth. Table 2 summarizes this experiment.

In subsequent experiments with other strains of chickens, diets containing lower levels of tryptophan than diet 3 (see Table 1) had to be used in order to obtain similar results, that is, baby chicks from early-feathering broiler strains (some of which actually have well-developed feathers at the time of hatching) fed diet 3 exhibited some feather development, cartilage formation and connective tissue growth, although they did not gain in body-weight. Investigations are in progress to see if birds of this type are adversely affected by being held six months at the 100 g stage. We are finding with such early-maturing strains that successful stasis is attained by feeding the deficient diets very shortly after hatching.

Symbiotic Association between Zooxanthellae and Two Marine Sponges of the Genus *Cliona*

THE association between Zoochlorellae and some fresh-water sponges of the family Spongillidae is well known for its constancy and has been well studied[1]. In the case of similar associations of Zoochlorellae with the fresh-water hydroid *Clorohydra viridissima*[2] and of Zooxanthellae with the sea-anemone *Anthopleura elegantissima*[3], the occurrence of a direct transfer of material from the autotrophic symbiont to the tissues of the Coelenterates has been demonstrated.

On the contrary, the occurrence of Zooxanthellae in marine sponges is a rare event and up to now it has not been sufficiently studied. Zooxanthellae have been found only occasionally in the superficial parenchyma layers of *Ircinia variabilis*, *Myxilla* sp., *Merlia normanni*, *Reniera* sp. and in tubes of *Clathrina* sp.[4].

Our observations have been performed on two species of marine and boring sponges of the genus *Cliona*, *C. viridis* and *C. copiosa*. *C. viridis* generally lives at a depth of some metres while *C. copiosa* is an allied species living in lightened caves near the surface. The external colour of these two species is variable; in general, *C. viridis* shows a dark green colour which changes to brown in the case of *C. copiosa*. The internal part of both sponges is yellowish to greenish. Specimens of both species were collected in different Mediterranean stations (Bay of Naples and along the coast of Ligury and Puglie) as well as at different depths and at different times of the year. In all cases a great number of Zooxanthellae were found embedded in extracellular arrangement in the sponge parenchyma (Fig. 1) and more densely near the surface of the sponges. These Zooxanthellae exhibit a yellow-greenish colour with a blood-red fluorescence under Wood's light. In addition, they possess two flagellæ and measure 7·5–9μ in diameter.

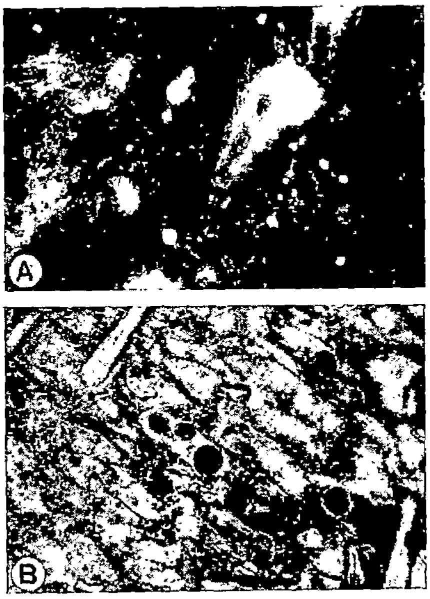

Fig. 1. Zooxanthellae in the sponge tissue observed (*A*) in Wood's light and (*B*) after fixation in formol and staining in Heidenhain hæmatoxylin–eosin

In the case of the associations between Zooxanthellae and Coelenterates, many investigators have considered that carbon dioxide, as well as other animal catabolites. may be essential for the metabolism of the autotrophic symbiont and that, on the other hand, the removal of carbon dioxide may be of some use for the associated animal[5]. The possibility of relationships between the occurrence of Zooxanthellae and the behaviour of *Clionidae*, boring in calcareous rocks and shells, must, therefore, be taken into consideration and deserves to be further investigated in greater details.

ENTOMOLOGY

Inhibition and Excitation in the Acoustic Behaviour of *Pholidoptera*

EXPERIMENTS on the 'bush cricket', *Pholidoptera griseoaptera* (De Geer), using artificial signals[1] have shown that these have an inhibitory effect on chirping. Further work has shown that the chirping of one male has a similar inhibitory effect on other males. In addition to their inhibitory effect, artificial signals increase the overall chirp rate and alter the timing of chirps so that they tend to occur in the first second after the end of the inhibitory period. These excitatory effects are shown when the total basic chirp rate is below 30 per min; the signals actually depress the chirp rate when it is high.

Inhibition during the signal and an overall increase in chirp rate are shown when consecutive periods of 5-sec signal and 5-sec silence are used (pure tone signals 10–15 kc/s, 65–80 db rel. to 0·0002 dyne/sq cm). In addition to these effects, the alteration in timing of the chirps can be seen in experiments using a 1-sec signal every 5 sec. Fig. 1 shows the pattern obtained when the results of five 2-min experiments of this type are added together. The number of chirps occurring in the first sec after the end of the signal is much greater than could be expected if the signals were purely inhibitory. There is evidence from other experiments that in the range 40–80 db both the inhibitory and the excitatory effect of the signal are increased by an increase in intensity.

The chirp rate of each male is very variable and seems to be influenced by a number of factors such as time of day, temperature, reproductive state and auditory stimuli. Thus two males singing together may have very different chirp rates. When one or both are chirping at a high rate (total chirps 50-80/min) the song of one can be seen to have an inhibitory effect on the other. Fig. 2 shows examples of the interaction of two males. In the upper oscillogram one male is more active than the other, and in the lower they are equally active and chirp in phase for a short period during alternation. It is noticeable that they are not perfectly in phase and that the change from equal alternation to singing in phase and back is very sharp.

Measurements taken from 10 min of this recording (temperature 18° C) show that for a male chirping without intervention by the other male the interval has a mode of 0·9 sec (interval = end of one chirp to beginning of next). If the other male sings during the interval the mode is increased to 1·6 sec. The interval between consecutive chirps by different insects has a mode of 0·7 sec with a minimum of 0·5 sec. During this recording the two males sang in, or nearly in, phase more than 50 times. It is presumed that this happened because one had started to chirp before it had been inhibited by the chirp of the other. The maximum period between two 'in phase' chirps was in the region of 40–50 msec. This suggests that at 18° C the inhibitory reaction time is in the order of 50 msec. Two males with the same chirp period may sing in phase for as many as 4 consecutive chirps before the chirps become sufficiently out of phase for one to inhibit the other, so that they return to alternation.

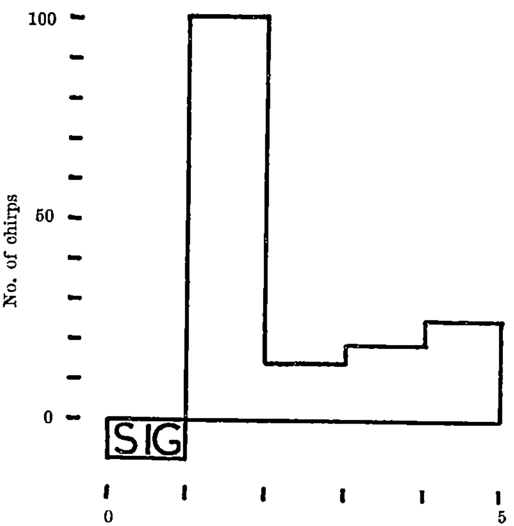

Fig. 1. Pattern of chirp emissions when a 1-sec signal is repeated every 5 sec. The results of five 2-min experiments are added together

The lengths of the intervals between chirps which are not in phase suggest that certain preparatory events must occur, perhaps in the central nervous system, before a chirp is produced. If the insect is inhibited during this preparatory period, the whole process has to be repeated when the inhibition is over.

Singing in phase has been heard a number of times, but so far only one recording containing it has been made. Other recordings of active males show a similar relation between the other intervals measured, but the actual length of these varies from experiment to experiment. Although the interaction of 2 males which are chirping at a high rate tends to decrease the rate of both, there is evidence that interaction has a long-term excitatory effect.

The interval between the ending of a 1-sec signal (10 or 12 kc/s, 70 db) and the beginning of the following chirp (mode 0·3–0·5 sec, minimum 0·2 sec at 17° C) is shorter than the corresponding interval between alternating chirps. It seems probable that an increase in the length of the inhibitory period increases the excitatory effect and thus there is a shorter preparatory period before the chirp.

Inhibition appears to play an important part in the interaction of singing males. A period of inhibition seems to be followed by a period of increased excitation (or

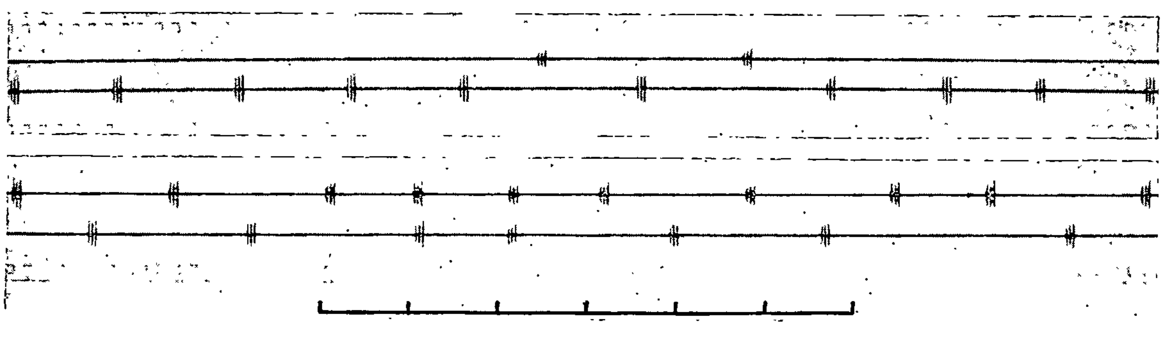

Fig. 2. The upper record shows the inhibitory effect of one male on the chirping of another. The lower record shows a change from equal alternation to 'in phase' and back again. Time marker, 1 per sec.

lowered threshold) and this may be an example of what Kennedy and Booth[2] have called "antagonistic induction". It is possible to interpret in this way a great deal of the information given by Busnel *et al.*[3] on the behaviour of *Ephippiger* males.

I thank Mr. W. B. Broughton for his advice.

Some Effects of Decapitation on Metabolism in *Rhodnius prolixus* Stål.

The failure of oocytes to develop in decapitated female *Rhodnius* has been attributed to the failure of protein synthesis[1], and Vanderberg[2] has shown reduction of incorporation of radioactive leucine by several tissues after decapitation. Further experiments have been performed on the fat body and hæmolymph to investigate this.

In the normal insect there are two main adult-specific hæmolymph proteins, formed in the fat body, which are absorbed by the oocytes and form the bulk of the soluble oocyte protein. Absorption has been demonstrated by oocyte uptake of hæmolymph proteins labelled with fluorescein, and the proteins examined by immuno-electrophoresis. Decapitation results in the failure of yolk deposition[3], and also results in the presence of only small quantities of the 'yolk' proteins in the hæmolymph, whereas after ovariectomy large accumulations of these proteins occur. No 'yolk' proteins are found in the fat body after decapitation, even though the protein content of this tissue is increasing and is higher than normal. Other hæmolymph proteins are formed; it appears, therefore, that the action of the corpus allatum hormone is on the specific synthesis of 'yolk' proteins by the fat body. This does not exclude the possibility that the hormone may also affect the uptake of protein by the ovary. Digestion is not a limiting factor, since high concentrations of amino-acids are found in the hæmolymph.

This makes the finding of Vanderberg[2], that synthesis of DNA occurs normally in the decapitated insect, but that synthesis of RNA is inhibited, very relevant, and implies that the gonadotrophic hormone acts at the level of RNA synthesis. This would fit in with the theory of Karlson[4], who thinks that the moulting hormone acts on the chromosome to produce puffs, and that these puffs are the site of synthesis of RNA. It is relevant to note here that Wigglesworth[5] suggested that the juvenile hormone, which appears to be identical with the gonadotrophic hormone[6], must act in the larval instars on the gene-controlled system of the epidermal cell.

The demonstration of the possible action of the gonadotrophic hormone helps in the understanding of the control of metabolism in the fat body of the fifth instar. Wigglesworth had noted that the fat body grows more slowly in the decapitated larval insect than in the normal one[5], but that this is not due to the moulting hormone[7]. Investigations of concentration of amino-acid in the hæmolymph suggest that, on decapitation in the fifth instar, digestion is not limiting. Changes were followed over the first nine days after decapitation, and it was found that, on decapitation at 0–1 h after feeding, net protein release into the hæmolymph (mostly from the fat body) is normal. However, the relative amounts of the two main hæmolymph proteins, as separated by cellulose acetate electrophoresis nine days after feeding, depend on the time of decapitation. Accumulation of protein in the fat body occurs, but more slowly than normal. Glycogen is also stored in the fat body, in small quantities after decapitation 0–1 h after feeding, but in larger quantities 24 h after decapitation. On the other hand, the fat content of the fat body remains low after decapitation at either 0 or 1 day after feeding. It is suggested that the most economical hypothesis to explain these results is that the brain hormone is acting on the chromosomes of the fat body, and that different genes are responding to different concentrations of the hormone.

Effects of Low-temperature Storage on the Eggs of *Spodoptera littoralis* (Boisd.)

In September 1963 a number of growers reported severe damage to the flowers and foliage of all-year-round chrysanthemums by a new caterpillar which, when more than half-grown, was apparently resistant to DDT. The larvæ were later determined as *Spodoptera littoralis* (Boisd.) (*Prodenia litura F.*) (Lepidoptera: Noctuidae), an important pest of cotton and many other crops in African and Mediterranean countries. Experiments showed that dichlorvos at 24 c.c. of 50 per cent emulsifiable concentrate per gallon per 600 sq. ft. of bed could kill larvæ up to the third instar. The older larvæ were susceptible to 0·04 per cent dieldrin as a stomach poison. The pest was afterwards eliminated from the nurseries on which it had appeared by the combined use of these two materials.

When the history of the individual outbreaks was examined they could all be traced back to cuttings which had been taken in the Canary Islands. *S. littoralis* is a serious pest of tomatoes in the Canaries after being introduced there many years ago following an abortive attempt to cultivate cotton. The production of cuttings in the Mediterranean area to take advantage of high winter light intensity is becoming an important feature of chrysanthemum production in north-west Europe. Some quarantine method to ensure that *S. littoralis* is not spread by the trade in cuttings is therefore highly desirable. As cuttings are frequently cold-stored for several days to facilitate handling procedures it seemed that the survival of *S. littoralis* under these conditions should be investigated.

In the laboratory egg-masses obtained from cultures of *S. littoralis* reared on chrysanthemum were divided into two so that every replicate had its own control. The eggs were placed on plastic gauze suspended over wet filter-paper within plastic pill-boxes with tightly fitting lids. The controls were kept at 75° F but the boxes to be treated were placed in a laboratory refrigerator maintained accurately at 35° F. After the requisite periods of treatment the boxes were returned to 75° F for at least one week to test viability.

Other tests were made in commercial cold-stores with eggs, which were obtained directly from the Canary Islands. Within a few hours of landing each egg-mass was divided at the Glasshouse Crops Research Institute and placed in pill-boxes as before. The controls were incubated at 75° F while the boxes due for treatment entered the cold-stores about 1 h. later. Each pill-box was placed among chrysanthemum foliage within the polythene sheets used to surround each batch of cuttings in the standard cardboard storage packs. As before, viability was tested by returning eggs to 75° F for one week.

Temperature records were taken over a period of one week in the stores with six recording thermographs (loaned by Meteorological Office), and throughout the period the temperature remained between 30°–35° F.

From Table 1 it is apparent that exposure at 35° F for longer than 5 days reduces the viability of the eggs and that after 10 days none remains viable. The 2–6 week exposures to cold were made to ensure that no induction of diapause had been caused by preliminary exposure to 35° F. The prolonged period at low temperature would normally end such diapause and the eggs therefore resume development at 75° F. No such effect took place and it seems quite clear that the eggs are definitely killed by prolonged exposure to low temperatures.

Table 1. VIABILITY OF EGGS OF *Spodoptera littoralis* FOLLOWING STORAGE AT 35° F IN THE LABORATORY

Age when introduced to cold (days)	Duration of storage (days)	No. eggs		% hatch	
		Treated	Control	Treated	Control
1	5	94	32	100	100
2	5	83	24	100	100
2	7	70	81	8·6	100
2	7	251	63	0·4	100
1	10	117	17	0	100
2	10	112	19	0	100
0–3	10	448	632	0	91
? (Field collection Canary Is.)	10	194	160	0	100
2	14	187	21	0	100
2	21	69	84	0	100
2	42	142	27	0	100

The viability of eggs which experienced low temperatures in the commercial stores (Table 2) confirmed that unless chilled for 10 days some hatching might occur. The highest hatch recorded for 7 days' exposure was 18·4 per cent, so that the complete mortality found after 10 days might, in fact, also have been found at 9 days had this been tested.

Table 2. VIABILITY OF EGGS OF *S. littoralis* FOLLOWING LOW-TEMPERATURE STORAGE IN COMMERCIAL CUTTING STORES

No. egg masses tested	Duration of storage (days)	Mean temp. (°F)	No. eggs		% hatch	
			Treated	Control	Treated	Control
15	10	30–35	1,766	1,012	0	100
11	7	30–35	889	629	13·5	100
3	7	31–34·5	187	102	0	100
1	5	31–34·5	58	42	3·5	100
1	5	31–34·5	118	94	12·0	100
1	6	31–34·5	128	35	3·9	100
1	7	31–34·5	127	67	0·8	100
23	7	31–34·5	2,320	1,831	18·4	100

The results obtained by exposing eggs at high humidity both in refrigerators and within boxes of chrysanthemum cuttings in cold-stores approximates to the conditions eggs would experience if actually laid on the leaves of cuttings which were subsequently cold-stored. No viability was detected in eggs kept at 35° ± 1° F or 30°–35° F for more than 10 days, but as 18 per cent hatched after 7 days' exposure it is unlikely that exposures below 10 days could be relied on to prevent hatching completely. As a practical quarantine practice, therefore, holding plants, subject to oviposition by *S. littoralis* for 10 days at temperatures of 35° F or below, should safely eliminate infestation. So long as the cold-rooms used for storage had suitable continuous temperature recording equipment, shipments treated in this manner could be safely cleared.

CYTOLOGY

Autopolyploidy in *Asplenium*

Asplenium rutamuraria L. and *A. septentrionale* (L.) Hoffm. are two very distinct and well-defined species of ferns, generally distributed throughout Europe, and also possessing wide but interrupted ranges around the northern hemisphere. Previous to this communication, all the chromosome counts in these two species known to me, whether from Europe[1,2] or elsewhere[3,4], have indicated that both are exclusively tetraploid, with $n = 72$ chromosomes.

A report was recently published[5] concerning the surprising chromosome pairing found at meiosis in an example of a wild hybrid between these two species. This plant, originally collected in Borrowdale, Cumberland, showed as many as 64 bivalents out of a possible maximum of 72. More recently, fixations from another example of this hybrid growing wild in Canton Ticino, Switzerland, have been available for investigation, provided by Prof. T. Reichstein of Basle. A high proportion of cells from this plant show complete or virtually complete pairing (Fig. 1). It seems very likely, in view of the fact that *A. rutamuraria* and *A. septentrionale* are two very different species, that all the bivalents observed in these hybrids are produced by autosyndetic pairing. Evidence in support of such a conclusion can be adduced from investigation of chromosome pairing in hybrids formed between *A. septentrionale* and other species of *Asplenium*[6]. This conclusion clearly involves the implication that diploid forms of both *A.*

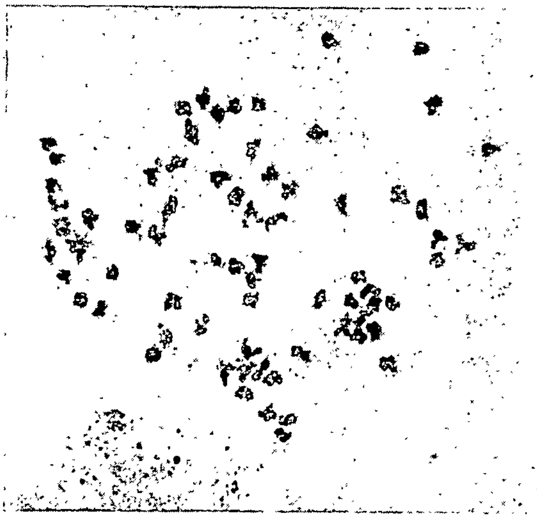

Fig. 1. Diakinesis from wild fixation of *Asplenium rutamuraria* × *septentrionale* at Bigorio, Ticino, Switzerland, showing $n = 72$ bivalents (× 1,000)

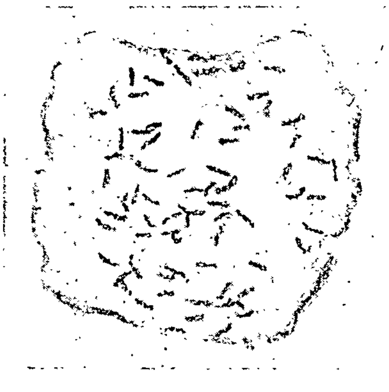

Fig. 2. Root-tip mitosis in *A. septentrionale* from the Western Caucasus, showing $2n = 72$ chromosomes (× 1,000)

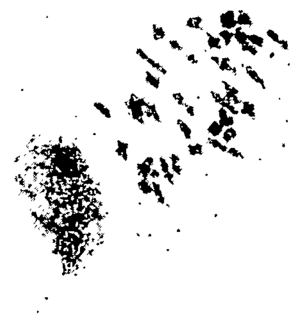

Fig. 3. Meiotic metaphase in *A. rutamuraria* from the Buco di Vela, North Italy, showing $n=36$ bivalents (× 1,000)

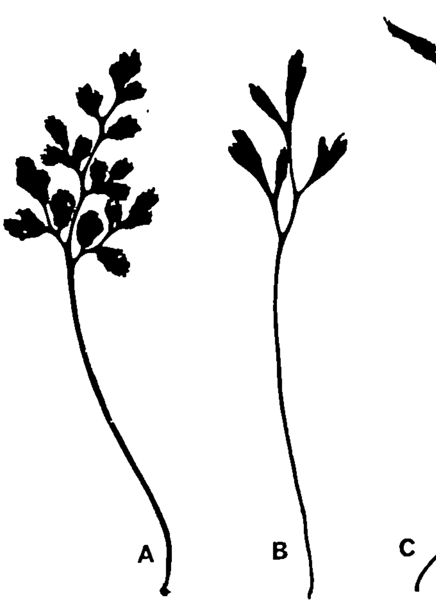

Fig. 4. Silhouettes (natural size) of fronds of the tetraploid hybrid *Asplenium rutamuraria* × *septentrionale* (B), and its parent species, *A. rutamuraria* (A), and *A. septentrionale* (C), all pressed from the wild. Bigorio, Ticino, Switzerland (September 12, 1963)

rutamuraria and *A. septentrionale* must have existed in the past, and might indeed still be alive to-day. Search has consequently been made for such plants, with the result that extant diploid forms of both *A. rutamuraria* and *A. septentrionale* have now been found.

The diploid form of *A. septentrionale* is as yet known to me only as a culture raised in Leeds from dried fronds obtained by exchange with the Moscow Botanic Garden. This material originated directly as part of a wild collection made in the Western Caucasus. Chromosome counts have been obtained both from meiosis and mitosis (Fig. 2).

The probable existence of an extant diploid form of *A. rutamuraria* became evident after a putative hybrid between *A. lepidum* C. Presl (another species known to be tetraploid[6,7]), and *A. rutamuraria* detected by Prof. Reichstein in the possession of Herr Th. Egli of Canton Zurich, Switzerland, had proved to be triploid, and not tetraploid, as is usual for this hybrid[6]. This plant had originally been collected by Herr Egli from the Buco di Vela near Trento in North Italy. Material of *A. rutamuraria* from this locality was already in cultivation in Basle and proved on cytological examination to be diploid (Fig. 3). Since then, diploid plants of *A. rutamuraria* have been collected by Prof. Reichstein and myself from several localities in the Italian Dolomites.

In both *A. rutamuraria* and *A. septentrionale*, the diploid cytotype is morphologically very similar to the tetraploid, but can be distinguished, particularly by use of micro-characters. A cursory examination of the herbarium material available to me has not yet produced any extension of the very limited known ranges of either diploid, and it seems that both are in fact rare plants, now occupying distributions of a relict character. It follows that the two tetraploids, with their wide but disjunct distributions around the northern hemisphere, are probably of relatively ancient origin.

There appears to be little doubt that both tetraploid *A. rutamuraria* and tetraploid *A. septentrionale* are of effectively autopolyploid origin. The case of *A. septentrionale* is especially interesting, since this is a particularly distinct and extremely isolated morphological type, scarcely at all variable, and with no known close relatives. The facts clearly suggest that, at least in *A. septentrionale*, the tetraploid form may indeed have arisen by simple direct autopolyploidy according to the more restricted application of the term (that is, by doubling of the chromosome complement without the intervention of any act of hybridization), a process now believed[8,9] to be only very rarely a successful mode of speciation in Nature.

Taxonomic and cytogenetic investigation of the newly discovered diploids is now in progress.

I thank Prof. T. Reichstein for his help, Prof. I. Manton for her advice, and Herr Th. Egli for his co-operation. I also thank the Moscow Main Botanical Garden for the material of *A. septentrionale* from the Caucasus.

Measurements of Deoxyribonucleic Acid on Mammalian Germ Cells using the Integrating Microdensitometer

MICRODENSITOMETRIC determinations of the deoxyribonucleic acid (DNA) content of normal diploid cells and of tumour cells have already been reported[1-4]. In these measurements, cells known to be haploid, for example, spermatozoa, have been used as a baseline for ploidy measurements of other cells.

This communication deals with preliminary investigations of DNA measurements on Feulgen-stained rabbit germ cells using the Barr and Stroud *GN2* integrating microdensitometer. Incorporated into this instrument is an automatic scanning device with a small moving aperture 0·5μ in diameter. As the field area is scanned, instantaneous values of absorption are automatically integrated and the total field absorption is recorded as an integrated voltage on a relative absorption meter. By taking absorption measurements on fields with and without the specimen, and then taking the simple numerical difference between the two readings, an absolute absorption of the specimen, in arbitrary units, is obtained.

Follicular ova and ejaculated spermatozoa which have a theoretically constant DNA content were selected for the examination. Follicular eggs remain in the first meiotic prophase until just prior to ovulation, and thus theoretically contain a tetraploid (4*n*) amount of DNA. Ejaculated spermatozoa, having completed both meiotic

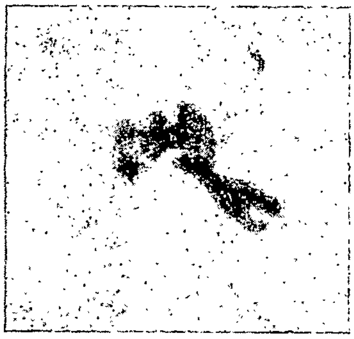

Fig. 1. Feulgen-stained nucleus of a follicular ovum

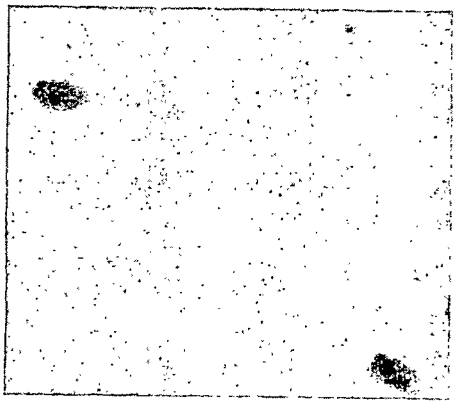

Fig. 2. Feulgen-stained nucleus of a spermatozoon

divisions, contain a haploid (1*n*) amount of DNA. The selection of these two particular cell types has the further advantage of comparing the measurements of regular- and irregular-shaped nuclei (Figs. 1 and 2).

Follicular eggs and ejaculated sperm were collected from New Zealand White rabbits according to methods previously described (Burks and Davis, in the press). The cells to be measured were squashed in 45 per cent acetic acid, fixed in acetic-alcohol, and stained by the Feulgen reaction. Multiple DNA measurements were taken on individual nuclei of six follicular eggs and six sperm at a wave-length of 5460 Å.

Comparing measurements made on follicular eggs and ejaculated sperm one would expect to find a DNA ratio of 4 : 1. The actual measurements approach this theoretical ratio. The follicular ova measure 14·7 ± 1·3856 arbitrary units of DNA; the sperm, 3·8 ± 0·3286 arbitrary units of DNA, giving a measured ratio of 3·9 : 1 (Table 1).

Table 1

Germ cell type	Ploidy	DNA (arbitrary units)	*S.D.*	Theoretical	Observed
Sperm	1N	3·8	± 0·3286	1	1·0
Follicular egg	4N	14·7	± 1·3856	4	3·9

In order to obtain maximum accuracy of measurement, the readings of clear field absorption (background) should always be the same. The nature of the present material makes it impossible to take consistent background readings. As the sperm have the more regular-shaped nuclei, it was decided to standardize the background absorptions and resulting DNA content of the ova with reference to the background readings obtained from the sperm. The proportionate size of the sperm nucleus in relation to the measured field area is more nearly constant than is that of the ovum. Our correction factor consists of the ratio of egg background absorption divided by sperm background absorption multiplied by the original calculated DNA content of the follicular egg. The density of the clear areas in the field was standardized when measuring the specimen, thereby leaving only one variable to be read by the microdensitometer, that is, the absorption of the specimen. In doing so, it was found that the estimated DNA content of the eggs and sperm fall into the theoretical ploidy ratio of 4 : 1.

Any system is of value only in so far as it is reproducible. To test this property of the system, it is irrelevant whether one takes one measurement on each of many cells containing the same DNA content or whether one takes multiple measurements on a single cell. The accuracy and reproducibility of the system will be apparent in either case. In these preliminary investigations, multiple measurements were taken on six of each type of germ cell. The results indicate that the measurements are reproducible. The correction factor allows one to use this system of measurement to obtain accurate readings of DNA content within a small range of standard deviation. Thus, it seems that the integrating microdensitometer which provides a reproducible method of comparison of DNA content in irregularly distributed nuclear material and in regular ovoid nuclei may be satisfactorily used for the assessment of the ploidy of germ cells for examination of germ cell maturation and *in vitro* fertilization. Work is in progress measuring the ploidy of polar bodies and pronuclei in order to follow the maturation of the female germ cell and to ascertain whether or not eggs have been fertilized *in vitro*.

SOIL SCIENCE

Soluble Phosphate in Soil and Uptake by Plants

THE phosphate potential, defined by Schofield[1] as $\frac{1}{2}p\mathrm{Ca} + p\mathrm{H_2PO_4}$, has proved useful in describing the solubility of soil phosphate. However, Schofield went further and made out a case for the phosphate potential as one parameter of phosphate availability to plants, the other being the pool of labile phosphate measured by isotopic exchange. There is little doubt that plants may get insufficient phosphate because the concentration in the soil solution is too low, but it has not been shown whether this is due to concentration *per se*, or to a too-low potential (using Schofield's terminology)[2]. The following experiment, which was carried out as part of a broader investigation, suggests an answer.

Italian ryegrass ('Aberystwyth *S*22') was sown in pure sand at the rate of 0·25 g per 4·5 in. diam. pot. After a germination period of 8 days, nutrient solution was dripped on to the surface of the sand at a rate of 500 ml. per 24 h, the excess liquid running to waste through holes in the bottom of the pot. Phosphate as $\mathrm{NaH_2PO_4}$ was made to concentrations of 0·1, 0·5 or 2·5 p.p.m. phosphorus, which covers the range normally found in soil solutions. With each phosphate concentration, calcium + magnesium concentrations of $1{\cdot}65 \times 10^{-2}$ M or $3{\cdot}12 \times 10^{-3}$ M were used, which again approximate to that found in soil solutions. The molar ratio of Ca : Mg was 3 : 1. All solutions contained 2 m.equiv. $\mathrm{K^+}$ per l., 12 m.equiv. $\mathrm{NO_3'}$ per l., and micronutrient elements as recommended by Hewitt[3]. Additions of $\mathrm{Na_2SO_4}$ were made so as to give a total salt concentration of 2×10^{-2} M. The *p*H values were 5·40–5·89. Treatments with high calcium concentrations were replicated six times, those at low concentrations three times.

Table 1

P concentration (p.p.m.)	Ca concentration (10^{-3} M)	P potential	D.M. tops (g)	P in tops (mg)
0·10	3·1	6·97	0·347 ± 0·027	0·32 ± 0·017
	16·5	6·64	0·349 ± 0·013	0·32 ± 0·024
0·50	3·1	6·27	0·757 ± 0·043	1·68 ± 0·069
	16·5	5·94	0·707 ± 0·010	1·45 ± 0·045
2·50	3·1	5·57	1·229 ± 0·063	5·44 ± 0·066
	16·5	5·24	1·152 ± 0·021	5·52 ± 0·100

After 21 days of treatment the grass was cut, dried at 80° C and weighed. It was dry-ashed and analysed for phosphate by the vanadomolybdate method. The roots were not weighed or analysed.

The results in Table 1 show that where phosphate is the limiting growth factor a five-fold change in the concentration of calcium has no significant effect ($P = 0\cdot05$) on the yield of dry matter. At the low and high phosphate levels the phosphate content of the leaves is not affected by the calcium concentration, but at 0·50 p.p.m. phosphorus it is significantly reduced ($P = 0\cdot05$) by the high concentration of calcium. This latter result, which is conceivably due to precipitation of calcium phosphate, is in the opposite direction to that which would be predicted by the phosphate potential. It is, therefore, concluded that, with solutions of about the same composition as those in soil, it is the phosphate concentration and not the potential which determines phosphate uptake by plants, though it is not certain whether the concentration should be expressed as the total inorganic phosphate or as H_2PO_4' ions.

In analysing soils for soluble phosphate, ideally the soil solution should be used, but because the solution is difficult to obtain in sufficient amount for analysis the soil is sometimes shaken with a dilute solution of a calcium salt, for example, 0·01 M $CaCl_2$ (refs. 4 and 5). As an alternative this should be satisfactory so long as the soil solution itself is about 0·01 M in calcium; but there seems no case for expressing the results as potentials when considering uptake by plants.

Effect of Chemical Weathering on Parent Material

THE summary by Keller[1] indicates that little progress has been made recently in the qualitative assessment of chemical weathering, since the equations of soil property by Jenny[2] and weathering rate by Jackson *et al.*[3] have not been developed. Recently, Loughnan[4] discussed several important aspects of weathering; but his paper is neither complete in itself nor intimately related to the main equations. The purpose of this communication is to elaborate on the last variable, 'parent material', in the equation of Jenny[2] with the aid of the recent data of Bayliss and Loughnan[5,6], Craig[7], Loughnan and Bayliss[8], and Loughnan *et al.*[9,10].

The variable of 'parent material' is subdivided into three factors: first, porosity and permeability—the quantity of fluid able to enter and flow through a rock; secondly, surface area—the extent of the area, which the fluid may attack; and thirdly, mineral structure—the susceptibility of the minerals in a rock to chemical weathering. The factor, 'mineral structure', is equivalent to the 'leaching index number' of Jackson *et al.*[3] and the 'persistence series' of Pettijohn[11]. These series are consistent with the results obtained from an approximately neutral oxidizing environment, although important exceptions are noted if the prevailing habitat is either acid (pH 4) or alkaline (pH 10), especially if the conditions are reducing rather than oxidizing.

To account for these exceptions in the equation the factor 'mineral structure' is further subdivided into the components of bonding energy, solubility, electrostatic stability and steric hindrance. The bonding energy for each of the main silicate groups, which is essentially controlled by the percentage of the strong silicon to oxygen bonds, has been calculated by Keller[12]. This series is shown by Keller[1] to be similar to the stability series of Goldich, the order of crystallization by Rosenbush, the reaction series of Bowen and the classification of silicates by Strunz. The second component, solubility, which is markedly affected by both the pH and Eh, is taken from a solubility product. If, however, this information is unavailable, then the ionic potential of Goldschmidt[13] gives an approximate value. This factor is important because it controls the differential movement of the various ions after release from the structure. Electrostatic stability of a crystal, the third component, depends on the local distribution of charge, which is a resultant of the intensity and position of the individual atoms. Any charge concentration will provide a nucleus for chemical attack. The fourth component, steric hindrance, is created by the structural configuration. A framework structure traps a highly mobile ion compared with that of an open structure.

An example of chemical weathering, that is, illite compared with vermiculite (another 2 : 1 layer lattice silicate), is taken to illustrate the four components of the factor 'mineral structure'. First, from Keller[12], the bonding between oxygen and aluminium in illite is stronger than that between oxygen and magnesium or ferrous iron in vermiculite. Secondly, from Loughnan[4] the aluminium in illite is less soluble than the magnesium or ferrous iron in vermiculite. Thirdly, the interlatered cation is shown by Bassett[14] to occupy a more stable electrostatic environment in illite compared with vermiculite. The fourth and final feature is the more difficult penetration of percolating fluids through the gap between the 2 : 1 layers of 1 Å in illite compared with 5 Å in vermiculite.

PSYCHOLOGY

Taste Sensitivity and Food Deprivation, Blood Sugar Level and Composition of Meal

IN a recent communication, Berg *et al.*[1] cite Dell[2] that "a hungry animal is considered to be in a state of high nervous irritability leading to a heightened level of sensory and motor excitation. As glycogen stores are depleted, blood glucose levels decrease, circulating epinephrine rises and stimulates the reticular formation of the brain, which in turn produces cortical arousal and facilitation of motor

Table 1. Mean Values of Blood Sugar Levels and Thresholds for 'Sweet' and 'Salt'

Taste quality	Condition	No. of days	Subject H				Subject R			
			Threshold in scale steps		Blood sugar (mg/100 ml.)		Threshold in scale steps		Blood sugar (mg/100 ml.)

* Caloric value 508 (subject H); 759 (subject R). Composition: approximately 54 per cent carbohydrate; 9 per cent protein and 37 per cent fat.
† Caloric value as above. Composition: approximately 40 per cent protein and 60 per cent fat.

and sensory activity, lowering the threshold for all external sensory stimuli". This implies that with increasing hours of food deprivation sensory acuity in all modalities increases and, further, that blood glucose level is an important factor in this relationship. However, with respect to taste sensitivity it appears probable that neither of these implications is correct.

Certainly, a number of investigations have shown that, in human beings, taste sensitivity increases from soon after breakfast to just prior to the mid-day meal and tends to increase further if no lunch is taken[3–6], or to decrease after lunch depending on the caloric value of the meal[5,6], followed by a tendency to increase again in the late afternoon[3–6]. These results may be interpreted as suggesting a direct relationship between time since ingestion of food and taste sensitivity, and an inverse relationship between blood sugar level and taste sensitivity.

However, while the results of Goetzl *et al.*[3] show a further tendency to increased sensitivity in the late afternoon on 'no lunch' days, the results of Hammer[5] and Yensen[6] show the reverse tendency under this condition. Meyer[7] investigated taste sensitivity at 3-hourly intervals over a period of 34 h of fasting and reported no systematic changes. Yensen[6] noted certain defects in Meyer's investigation and found that when subjects fasted from the previous evening meal until after the late afternoon test session on the following day, taste sensitivity at 9 a.m. was significantly higher ($P < 0·01$) than the 9 a.m. levels on days when breakfast was eaten. On fasting days sensitivity varied significantly ($P < 0·01$) with time of day for all taste qualities except 'bitter' with one subject. In all cases the 11.30 a.m. thresholds were the lowest, with the 2.15 and 4.45 p.m. thresholds tending to increase. Even though reports of increasing hunger were made towards the end of the 21-h fasting period, taste sensitivity tended to decrease after the first 16 h of fasting. Thus it appears that up to a certain time taste sensitivity may increase with increasing hours of food deprivation, but that hereafter it decreases, at least up to 21 h of fasting.

During the course of a wider investigation of the influence of certain factors on taste sensitivity, it was necessary to look briefly at the relationship, if any, between blood sugar levels and taste sensitivity[8]. Absolute thresholds for 'sweet' (sucrose) and 'salt' (sodium chloride) were assessed with two subjects under conditions of widely varying blood sugar levels (Table 1). Test sessions, involving four threshold determinations per session, were conducted at 10 a.m. and 12 p.m. over 2 or 3 days for each condition. Details of overall control of subjects and of the test procedures used have been reported elsewhere[8,9]. Capillary blood samples were taken immediately before each session. Blood sugar determinations (Hagedorn ar Jensen's method[10]) were made daily by arrangement wi Mr. S. E. Davison at the John Bonnett Clinical Labor tories, Addenbrooke's Hospital, Cambridge. The me thresholds and the mean blood sugar levels for each under each condition are presented in Table 1.

Inspection of Table 1 reveals no evidence of a systemat relationship between blood sugar levels and tas thresholds. For example, in each of the six sessio directly following glucose ingestion, blood sugar levels 121 mg/100 ml. and over are accompanied by threshol which are lower (significantly so in five cases; $P < 0·0$ than those under the 10 a.m. C.P.F.-breakfast conditio which yielded blood sugar levels between 90 and 1 mg/100 ml. On the other hand, all thresholds followi the C.P.F.-breakfast decrease significantly ($P < 0·01$) fro 10 a.m. to 12 p.m. with the variation in blood sugar leve following the same trend.

Finally, it is interesting to compare the effects of t carbohydrate–protein–fat and the protein–fat breakfas Although both are of equal caloric value, blood sugar leve increase following the former and decrease after the latt as compared with fasting levels. Under the C.P. breakfast conditions the 10 a.m. thresholds are signi cantly higher ($P < 0·01$) than the 12 p.m. thresholds, b this is not so under the P.F.-breakfast conditions. Furth at 10 a.m. the C.P.F.-breakfast thresholds are significant higher than the P.F.-breakfast thresholds, while 12 p.m. they are significantly lower ($P < 0·01$).

Since these two are of the same caloric value, the fo going results suggest that the composition of the me (that is, carbohydrate–protein–fat versus protein–f influences sensitivity to sweet. The P.F.-meal does n raise the sweet threshold as high as the C.P.F.-meal, b its elevating influence is still present 3 h after the ingesti of the meal, by which time the influence of the C.P. meal has largely disappeared.

FORTHCOMING EVENTS

Monday, July 20

Zoological Society of London and the Anti-Locust Research Centre (at the Zoological Society of London, Regent's Park, London, N.W.1), at 10.30 a.m.—Symposium on "The Endocrine Control of Metabolism and Maturation in Insects".

Tuesday, July 21

Parliamentary and Scientific Committee, General Committee (in Committee Room 12, House of Commons, Westminster, London, S.W.1), at 5.30 p.m.—Prof. B. R. Williams and Mr. Robert Nield: "Relationship of Technological Research and Development to Economic Growth".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer or Assistant Lecturer in Applied Mathematics in the Faculty of Science—The Registrar, The University, Manchester, 13 (July 23).

Assistant Lecturer (with an honours degree in agricultural chemistry, biochemistry or chemistry, and preferably experience in animal nutrition) in Agricultural Biochemistry—The Secretary, School of Agriculture, West Mains Road, Edinburgh (July 24).

Lecturers (2) (suitably qualified and able to teach for the B.Pharm. (honours) degree and at postgraduate level) in Pharmaceutical Chemistry—The Secretary, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (July 24).

Post-Doctoral Research Assistant in the Department of Pure and Applied Chemistry, to join in polymer research with Prof. M. Gordon—The Registrar, The University of Strathclyde, George Street, Glasgow, C.1 (July 24).

Biochemist (with an honours degree in chemistry or biochemistry) at the Area Laboratory, West Park Hospital—The Group Secretary, West Park Hospital, Epsom, Surrey (July 25).

Lecturer (with a good honours degree and teaching or research experience and preferably an interest in computers) in Mathematics; and an Assistant Lecturer, Grade B (graduate, preferably with an interest in microbiology or food technology) in Biology at Grimsby College of Further Education—The Director of Education, Education Office, Grimsby (July 25).

Lecturer (with teaching and research experience in some branch of human or regional geography, preferably with interests in a tropical area) in the Department of Geography—The Registrar, The University, Newcastle upon Tyne, 2 (July 25).

Reader (preferably with a particular interest in electromagnetic phenomena and experience in the application of advanced mathematics to the problems of the electrical engineering industry) in Mathematical Engineering—The Staff Officer, College of Advanced Technology, Gosta Green, Birmingham 4, quoting Ref. 375/6 (July 25).

Research Assistant in Aeronautics (the field of research will be in aeronautics or aircraft structures)—The Secretary of University Court, The University, Glasgow (July 25).

Assistant Lecturer or Lecturer in the Department of Botany—The Registrar, The University, Liverpool, quoting Ref. CV/238/N (July 26).

Junior Research Fellow in Botany—The Registrar, The University, Sheffield (July 27).

Research Assistant (graduate in agriculture or agricultural science with a knowledge of nutrition, growth and development of farm livestock) in the Meat Animal Investigation Unit, Leeds University Farm, for work in connexion with an investigation of body composition by gamma radiation and ultrasonic methods—The Registrar, The University, Leeds, 2 (July 27).

Lecturer in Hydrogeology, and a Lecturer in Geology—The Secretary, University College, Gower Street, London, W.C.1 (July 30).

Part-time Demonstrators (2) in Geology (one post for geology graduates specializing in palæontology and stratigraphy, and one post for those specializing in petrology)—The Secretary, University College, Gower Street, London, W.C.1 (July 30).

Experimental Officer or Senior Experimental Officer (with a university degree or Higher National Certificate, and preferably a special knowledge of digital electronics and data handling systems) in the Department of Physics of the Faculty of Science, to take part in the experimental programme in nuclear physics associated with the heavy ion linear accelerator and other accelerators—The Registrar, The University, Manchester, 13 (July 31).

Lecturer (Grade II) in Physiology (for dental students)—The Registrar and Secretary, The University, Bristol (July 31).

Research Assistant (with a degree in pharmacology, physiology or a related subject) to join a team concerned with the identification of a urinary polypeptide which inhibits gastric secretion—Prof. H. O. Schild, Department of Pharmacology, University College, Gower Street, London, W.C.1 (July 31).

Assistant Lecturer (with an honours degree in physics and an interest in biology and electron microscopy) in Biophysics in the Department of Anatomy—The Registrar, The University, Manchester, 13 (August 1).

Research Fellow in Pure Mathematics—The Master, Corpus Christi College, Cambridge (August 1).

Assistant Lecturer in Biochemical Pharmacology—The Registrar, The University, Manchester, 13 (August 5).

Lecturer in Pharmacology—The Registrar, The University, Manchester, 13 (August 5).

Assistant Lecturer/Lecturer (with an interest in one or more of the following: meteorology, climatology, biogeography or cartography) in Geography—The Registrar, The University, Keele, Staffordshire (August 6).

Demonstrator in Geography—The Registrar, The University, Keele, Staffordshire (August 6).

Research Assistant (preferably with experience in the interpretation of air-photos and a degree in geography) in the Geography Department, to work on the organization and classification of the air-photo library—The Registrar, The University, Keele, Staffordshire (August 6).

Assistant Lecturer (with special interest in the application of techniques of physical chemistry to pharmacy) in Pharmacy—The Registrar, The University, Nottingham (August 8).

Lecturer or Assistant Lecturer (veterinary surgeon) in the Department of Veterinary Anatomy—The Secretary, The Royal Veterinary College (University of London), Royal College Street, London, N.W.1 (August 8).

Lecturer in Pure Mathematics—The Registrar, The University, Manchester 13 (August 10).

University Demonstrators (2) in the Department of Metallurgy—Secretary of the Appointments Committee of the Faculty of Physics and Chemistry, Chemical Laboratory, Lensfield Road, Cambridge (August 10).

Lecturer (with a special interest in genetics and cytology) in Botany in St. Salvator's College—The Secretary, University of St. Andrews, College Gate, St. Andrews, Scotland (August 15).

Research Fellow (with a Ph.D. and research experience, preferably theoretical, in elementary particle physics) in Elementary Particle Physics—The Secretary and Registrar, The University, Southampton (August 15).

Lecturer in Mathematical Statistics at the University of Sydney, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, August 21).

Reader in Experimental Psychology—The Registrar, The University, Hull (August 22).

Senior Lecturer or Lecturer in Geography at the Australian National University—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, August 24).

Associate Professor in Biology (in the field of statistical plant ecology); a Lecturer/Senior Lecturer in Biology (Genetics); a Lecturer/Senior Lecturer in Biology (Animal Ecology); and a Lecturer in Biology (mainly for first year teaching) in the School of Biological Sciences, University of Sydney, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, August 27).

Lecturer or Assistant Lecturer (specializing in either genetics or biochemistry) in Biology at the University of Basutoland, Bechuanaland Protectorate and Swaziland—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (August 30).

I.C.T. Fellow (with a Ph.D. or similar experience) in the Oxford University Computing Laboratory, to perform unsupervised research in any field relevant to computing machines—The Director, Oxford University Computing Laboratory, 9 South Parks Road, Oxford (August 31).

Lecturers in Psychology—The Secretary, Institute of Experimental Psychology, The University, 1 South Parks Road, Oxford (August 31).

Senior Research Officer (with special knowledge, preferably with research experience in some branch of numerical or non-numerical analysis)—The Director, University Computing Laboratory, 9 South Parks Road, Oxford (August 31).

Assistant Biologist/Sealing Officer (single, with a B.Sc. and aged between 22 and 45) in South Georgia, to carry out research work on seals, and supervise sealing—The Appointments Officer, Room 301, Department of Technical Co-operation, Eland House, Stag Place, London, S.W.1, quoting Ref. RC289/60/01.

Biologist (national of the United Kingdom or the Republic of Ireland, aged 24 to 35, with an honours degree in zoology and postgraduate experience in animal ecology) in Tanganyika, to carry out investigations connected with the management of wild life and to advise the Chief Game Warden—The Appointments Officer, Room 301, Department of Technical Co-operation, Eland House, Stag Place, London, S.W.1, quoting Ref. RC275/173/01.

Entomologist (with a degree in science or agricultural science, preferably with honours in zoology and experience in agricultural entomology) in Fiji, for biological control, experimental and advisory services, and other duties assigned by the Senior Entomologist—The Appointments Officer, Department of Technical Co-operation, Eland House, Stag Place, London, S.W.1, quoting Ref. RC213/62/03.

Lecturer or Assistant Lecturer in Geography—The Secretary, Sir John Cass College, Jewry Street, London, E.C.3.

Lecturer/Senior Lecturer (with a good honours degree and research/lecturing experience, and preferably with special qualifications in one or more of the following: meteorology, climatology or biogeography) in Geography—The Registrar, Portsmouth College of Technology, Commercial Road, Portsmouth, Hampshire.

Lecturer (well qualified candidate with teaching or industrial experience, preferably a combination of both) in the Department of Electrical Engineering—The Academic Registrar, Loughborough College of Technology, Loughborough, Leicestershire, quoting Ref. 20/G.

Lecturers or Senior Lecturers (2) in Food Processing and Engineering; an Assistant Lecturer or Lecturer in Physical Chemistry; and an Assistant Lecturer or Lecturer in Industrial Management and Liberal Studies—The Principal, National College of Food Technology, St. George's Avenue, Weybridge, Surrey.

Natural History Assistant with the Area Museum and Art Gallery Service for the Midlands—The Secretary, Area Museum and Art Gallery Service for the Midlands, Council House, Birmingham, 1.

Professor of Mathematics and Head of the Department of Mathematics; and Professor of Physics and Head of the Department of Physics—The Academic Registrar, Loughborough College of Technology, Loughborough, Leicestershire, quoting Ref. 17/G.

Research Assistant (suitable for graduate with a degree in biological sciences, chemistry or medicine) in Genetics, to take part in programmes designed to study (1) human chromosome abnormality and associated disorder; and (2) chromosome behaviour in normal and abnormal karyotypes—The Registrar, The University, Sheffield.

Senior Lecturer (preferably with administrative experience and a personal record of successful research in an industrial environment) in Chemistry—The Academic Registrar, Loughborough College of Technology, Loughborough, Leicestershire, quoting Ref. 16/G.

Specialist Pathologist (with medical qualifications registrable in the United Kingdom, and a recognized postgraduate qualification in pathology with a minimum of five years experience in the speciality) in the Medical and Health Department, Hong Kong—The Appointments Officer, Department of Technical Co-operation, Eland House, Stag Place, London, S.W.1, quoting Ref. RC205/81/018.

Statistician (Biometrician) (national of the United Kingdom or the Republic of Ireland, under 50, with an honours degree in mathematics, followed by postgraduate training in mathematical statistics and biometry) with the East African Agriculture and Forestry Research Organization, to be in charge of the statistical (biometrical) division, to carry out research under the general direction of the Director on statistical problems of importance to the research workers in the biological natural resources field, and to advise these research workers—The Appointments Officer, Room 301, Department of Technical Co-operation, Eland House, Stag Place, London, S.W.1, quoting Ref. RC213/214/02.

TECHNICAL ASSISTANCE FOR OVERSEAS MINING AND GEOLOGY

THE long-awaited report of the Committee on Technical Assistance for Overseas Geology and Mining under the chairmanship of Sir Frederick Brundrett was published on May 7 accompanied by a statement of Government policy on the Committee's recommendations*. The Committee had been appointed in April 1962 to report on the type of technical assistance which the United Kingdom could provide in geology and mining, and in particular to look into the functions and organization of a number of United Kingdom scientific establishments concerned with these fields.

The most important recommendation of the Committee, that the functions of the Geological Survey of Great Britain should be expanded to cover overseas work in geology and mineral assessment and that this should be accompanied by amalgamation with the existing Directorate of Overseas Geological Surveys, has been accepted by the Government. It is also agreed that as soon as possible the Extraction of Metals Group of the National Chemical Laboratory should be transferred to the Mineral Processing Division of Warren Spring Laboratory with the programme of which its research is already closely linked.

These steps towards the integration of organizations dealing with geology and mineral exploration on the one hand, and with mineral dressing and extraction metallurgy on the other, should be warmly welcomed. The expanded Geological Survey of Great Britain will in future fall into line with the United States Geological Survey, the French Bureau de Recherches Géologiques et Minières and the West German Reichsamt für Bodenforschung in concerning itself not only with the geology and mineral resources of the home country but also with those of overseas territories. The Geological Survey of Great Britain, founded in 1835, has provided the country with a set of geological maps second to none in the world and with a series of memoirs describing both the general geology and the mineral resources of the United Kingdom. In the production of these, the field geologists have been aided by a relatively small but highly skilled group of specialists in such fields as petrology, mineralogy, palæontology, geochemistry, geophysics and hydro-geology. Overseas Geological Surveys was set up in 1947 as the Directorate of Colonial Geological Surveys with the object of advising and assisting the Geological Survey Departments in the various Colonial territories, by whom the bulk of the field geologists were employed, and of affording them certain specialist services through its Mineral Resources, Geophysical and Photogeological Divisions. Under the proposed reorganization these specialist services would be reinforced by the Atomic Energy Division of the Geological Survey of Great Britain, the only branch of that organization which concerned itself to any great extent with overseas geology.

The often-quoted dictum that the primary aim of a geological survey is to produce geological maps is one which, though indisputable, can be open to misconstruction. The production of maps is indeed the basic long-term research of a geological survey, since geological maps are all in some measure interpretations which must be continually revised in the light of advancing knowledge and new techniques. A comprehensive geological survey to-day should involve a variety of specialist studies, some of them, geophysical, structural or sedimentological, carried out largely in the field, others dependent on the provision of up-to-date chemical, mineralogical, spectrographic, X-ray and electronic laboratory facilities. This is a reflexion of the fact that the past 20 or 30 years have seen a revolution in the techniques and instrumentation of geology, as was pointed out in the 1963 presidential address to the Institution of Mining and Metallurgy by Prof. K. C. Dunham.

The geological maps and accompanying memoirs provide the national store-house of information regarding the geology of any territory and indicate the areas in which more detailed exploration for mineral resources is worth while. The prosecution of these more detailed investigations is as important a duty of a geological survey as the production of the basic maps and memoirs. Much excellent work of this kind has been carried out both at home and in present and former Colonial territories overseas, but in general the geological surveys have been prevented by limitations of staff and of resources from conducting such investigations on anything like the necessary scale. Opinions differ as to the stage to which a State organization should prosecute mineral exploration before handing over to private enterprise, but it is significant that many of the countries in which mineral exploration is most active—Canada, Australia, the former French territories in Africa and, nearer home, the Irish Republic—are those where the State organization goes further in the exploration of areas of potential mineral wealth than has been customary either in the United Kingdom or in British Colonial and ex-Colonial territories.

The authors of the Brundrett Report clearly recognize the need for an extension in the activities of the expanded Geological Survey of Great Britain, in particular to provide mobile teams of geologists and mining engineers, skilled in economic assessment, to carry out technical assistance overseas. It may be added that were the fiscal climate at home a little more favourable to mining there would be opportunities to use these teams in the United Kingdom as well. These activities will call for a very considerable increase in staff, and perhaps the most disquieting aspect of Government reaction to the Committee's recommendation is the suggestion that this can be satisfied by the addition of four new senior posts on the complement of the Overseas Geological Surveys while the need for further appointments to the home establishment is kept under review. It cannot be too strongly emphasized that nothing less than a doubling of the present size of the combined home and overseas organizations will meet the needs of the present time. So great an expansion, entailing an increase both in field-staff and in specialists, including in particular geologists with economic experience, must be carried out over a period of years if the high standards of scientific ability which have been demanded by the geological surveys in the past are to be maintained.

Technical Assistance for Overseas Geology and Mining: Policy on the Recommendations of the Committee. Pp. 7. (Cmnd. 2352.) 8*d*. net. (London: H.M.S.O., 1964.)

However, at the present time there are able and experienced geologists from the staffs of the ex-Colonial surveys, not all of whom will wish to stay on under contract in the newly independent territories. An immediate and reassuring Government statement about the scale and scope of the new Geological Survey should lead many of these to transfer to its service at the same time as attracting a steady flow of the most able young graduates from the universities.

Apart from personnel, the reorganized Geological Survey of Great Britain will need enhanced laboratory facilities if it is to carry out the type of work, much of it of high economic importance, which is done by the United States Geological Survey. Among these facilities equipment for radiometric age determination and for electron micro-analysis may be mentioned since both can contribute significantly to understanding the origin and hence the distribution of ore deposits. In view of the spread of mineral exploration beyond the land masses some facilities for marine geology may also prove necessary.

The combined budgets of the existing Geological Survey of Great Britain and Overseas Geological Surveys are of the order of £1·75 million. Even double this figure would still compare poorly with the £7·25 million spent annually by the Bureau de Recherches Géologiques et Minières, three-quarters of it on work directly comparable with that envisaged for the expanded Geological Survey of Great Britain, let alone with the annual budget of the United States Geological Survey of more than 70 million dollars. In the light of the statistics quoted in the Brundrett Report, showing that in 1961 sixteen territories in which Overseas Geological Surveys have operated produced minerals to a value of more than £440 million, an annual expenditure of a few million pounds might seem an excellent investment.

Several recommendations of the Brundrett Committee are concerned with the general matter of publicizing the technical services available from the reorganized Geological Survey of Great Britain both to governments of developing countries and to the mining industry at large. British geologists and mining engineers have experience second to none to offer the newly independent nations, and, in return, Britain might hope to gain good will, markets for mining machinery and equipment and security of sources of mineral supply. Government reaction to these recommendations while acquiescent is largely unspecific as to how the object is to be achieved. It is suggested that opportunities should be afforded to political and official heads of departments visiting Great Britain to see the work being undertaken in the geological and mining fields, but it is ominous that now, when it is more necessary than ever before that the reorganized Geological Survey should be easily accessible, there has been talk of its headquarters being moved out of London. While it might well prove desirable to open somewhere in the south of England a branch office on the lines of those in Edinburgh, Belfast and Leeds, it would seem essential that the Directorate together with the bulk of the specialist staff, the headquarters of the mobile teams and the Museum of Practical Geology should remain in London.

From the aspect of publicity no less than of general policy, it is most regrettable that the Government has not been able to accept the Brundrett Committee's recommendation that a highly qualified advisory committee be established to consider problems of technical assistance and how they can best be met. Such a Committee would have to be in touch with the needs of developing countries, with long-term trends in demand for minerals and with all sources of technical assistance in geology and mining in the United Kingdom. It might go far towards framing, for the first time, a coherent mineral resources policy for Great Britain. The establishment as proposed by the Government of a committee of the Geological Survey Board, inevitably limited to considerations on a departmental level, would be no substitute for a top-level advisory committee. Any committee which is to be effective must be in a position to survey not only its own department but also all the facilities of the universities, the mining houses and the consultants.

The extent to which geological surveys should invite the co-operation of university staff in their work has always been a controversial problem. The Service de la Carte Géologique de France and the Service Géologique de la Belgique both rely largely on university personnel for their routine geological mapping. This system has disadvantages. It does not lead to the building up, within the organization, of the stock of experience and knowledge which the staff of a good Survey need. The Surveys do not have full administrative control of their collaborators or of their programme. Although there is much mapping ability in the universities many academics tend to be specialists in certain aspects of their science and would be reluctant to give all facets of the geology the impartial attention they would get from a professional surveyor. In specialist fields, however, the universities have much to offer, and in the reorganized Geological Survey with its greater emphasis on short-term work this will be more than ever the case. Overseas Geological Surveys have for a number of years made use of university personnel for special investigations, and their relations with the Centre for Geochemical Prospecting at the Royal School of Mines have been a particularly happy example of Survey–university collaboration. Both the British and Overseas Surveys have had fruitful co-operation with consultant firms in, for example, aerial or geophysical surveys or deep drilling.

On the subject of the provision of professional and technical training the Report might perhaps have laid greater emphasis on the importance of developing facilities for this in the newly independent countries. Many of the universities in these lands have close links with British universities, and it should be a matter of high priority to encourage the establishment and expansion of departments of geology and mining in them. While it is to be hoped that students from overseas will continue to attend British universities and schools of mines, the competition for places is likely to be severe for some time and the number that can be accepted must inevitably be limited.

The Brundrett Committee envisaged the combined Geological Surveys and the enlarged Mineral Processing Division of the Warren Spring Laboratory as both coming under the control of the Department of Scientific and Industrial Research. The recommendations of the Trend Report on the Organization of Civil Science, however, threaten to separate them and indeed to give rise to a disastrous fragmentation of what may be called the 'earth sciences', a coherent group including all aspects of geology, mineralogy, geochemistry, geophysics and physical oceanography. There is perhaps reason to hope that the original Trend proposals may be modified in such a way as to preserve the unity of the earth sciences, and it would facilitate the provision of technical assistance if geological surveys and mineral processing, even if not within the same organization, were at least controlled by the same department or research council. Many geologists will regret the passing of the Department of Scientific and Industrial Research which in the past has served the earth sciences well.

The Brundrett Committee interpreted its terms of reference as excluding any problems of financing mineral development. While no doubt it was right in this, there seems substance in the comment of a critical editorial in the *Mining Journal* of May 15 that the failure to direct attention to the consequences of divorcing financial from technical assistance is the Report's major weakness. Some mechanism must be developed whereby, when an area with economic possibilities is delimited, whether at home or overseas, Government can endeavour to interest private enterprise in its exploitation. The Bureau de Recherches Géologiques et Minières spends about a quarter of its £7·25 million annual budget on shares and partnerships in companies to exploit newly proved resources. The Irish Mianrái Teoranta carried development to a stage far beyond that hitherto envisaged by the British or Overseas Geological Surveys and financial assistance to mining companies was given by the Industrial Credit Co. on behalf of the Department of Industry and Commerce. In his 1962 presidential address to the Geological Society, Prof. S. E. Hollingworth speculated as to what the attitude in France or Germany would have been to the discovery of the substantial potash deposits of north-east Yorkshire, which, after ten years, are still undeveloped for technical reasons which do not appear insurmountable. In Great Britain the National Research and Development Corporation exists to develop and to exploit inventions where the public interest so requires, and of recent years the Department of Scientific and Industrial Research has placed contracts in industry for the development of new and technically advanced products. Is it too much to hope that in the reorganization of the facilities for technical assistance in geology and mining the opportunity may be taken to make comparable provision for the development of newly discovered mineral resources?

PLANT TAXONOMY SEEN AS A SCIENCE

Principles of Angiosperm Taxonomy

By Dr. P. H. Davis and Dr. V. H. Heywood. Pp. xx + 556. (Edinburgh and London: Oliver and Boyd, Ltd., 1963.) 95*s*. net; paper-back version, 75*s*. net.

THIS most welcome book is the first major work of recent times devoted to the theory of plant taxonomy. As a first approach to it, I recommend the reading of the four pages of conclusions that bring the text to an end. Not before has there been a clearer or more objective statement of the principles and issues involved in taxonomy to-day, nor rarely has there been a more categorical dispelling of humbug. For those who care for humbug in taxonomy—and these include both makers and users—there is much to shock and incense in these pages. If this impels them to a thorough study of the earlier chapters of *Principles of Angiosperm Taxonomy*, all to the good, for there they will find a rational and dispassionate exposition of a set of aims, methods and concepts for taxonomy which, when generally adopted, will bring it much nearer towards being a science than it has managed to be heretofore.

The authors' stance is revealed by their first three principles: "(1) Classification is a fundamental activity and is undertaken for primarily practical purposes. (2) Biological classification is an extension of general classification and is governed by the same basic principles. (3) Different classifications are needed for different purposes; no one classification can serve all purposes." Well said! It may be damaging to the mystique cherished by many who practise taxonomy to have these points so clearly put, but the more widely it is acknowledged that taxonomy is concerned first and foremost with the establishment of systems of classification with maximum utility as data storage and retrieval agencies, the better for biology as a whole. The corollary is that romantic notions about the place of phylogenetic speculation in taxonomy are overdue for abandonment. The authors make no bones about this issue, either. "In the Angiosperms," they say, "classifications based upon phylogeny are unattainable except for special cases, and then mostly at or near the species level. Because of the complexity and multi-dimensional nature of evolutionary relationships, what pass for such classifications vary from unconsciously phenetic classifications to distorted special classifications produced by unjustifiable weighting of characters." The phenetic classification which they themselves urge as the primary aim of taxonomy is one based on maximum correlation of attributes; that is to say, a natural classification in the original, pre-Darwinian sense. That natural classification should not mean automatically phylogenetic classification seems still to be a conception quite beyond assimilation for many, especially those with no very deep acquaintance with evolutionary mechanisms. Yet, as Davis and Heywood say, the conversion of true phenetic classification into something that might approach a phyletic one involves a whole series of problems of interpreting and weighting characters. The construction of phylogenetic shrubs and trees is an intriguing activity: nevertheless it is not taxonomy, but merely one use of the data of taxonomy.

Linked with their views on the basic function of taxonomy is the attitude of the authors towards the newer sources of taxonomic evidence, including cytology and plant-product chemistry. Their balanced appraisal of the potential role of the new kinds of data in general taxonomy merits attention from all who would over-value the classificatory significance of one or a few specialized criteria. Neither karyological nor phytochemical data, they say, have any special *a priori* claim to importance for comparative taxonomic purposes; surely an entirely valid conclusion, when both constitute merely expressions of the genotype in no way different from the more readily accessible morphological and anatomical characteristics.

The special significance sometimes assumed by cytological data—when, for example, a difference in chromosome number indicates a sterility barrier—is to be considered alongside experimental genetical observations bearing on the extent of breeding groups. The early enthusiasm for species concepts based on intersterility criteria never really impinged seriously on general taxonomic practice, and Davis and Heywood show once more why it cannot. They underwrite the view now gaining wider acceptance that classifications based on such criteria as gene exchange must be regarded as artificial, and as such to be designated by special terminologies.

I have emphasized in the foregoing paragraphs those characteristics which give *Principles of Angiosperm Taxonomy* its special and refreshing flavour; but in fact they constitute no more than one aspect of a very rich text. Sections are devoted to the history of taxonomy and taxonomic thinking and to the thoughtful discussion of the concepts of taxonomic categories and characters, while matters of taxonomic technique are treated as comprehensively and expertly as might be expected from two practitioners engaged themselves in major floristic research. The last five chapters (comprising rather more than 150 pp.) are devoted to experimental taxonomy and to the consideration of microevolutionary phenomena in plant populations. One can foresee a reviewer's point being made of the location of these chapters ("Can it be that the authors are looking at their subject upside down ? Can it be that they are actually unaware of the basic importance of genetics for their subject ?"), but the fact is that the taxonomic implications of population genetics and associated disciplines cannot be appreciated without an understanding of what taxonomy is all about in the first place.

An admirable book, then, destined to become a standard text in its own special field. For the practising taxonomist it is certainy obligate reading, whatever his present degree of enlightenment. From the non-taxonomic user of the products of taxonomy it deserves serious attention as a lucid and thoroughly documented treatment of the purposes and philosophy of a discipline frequently misunderstood and often misrepresented. For the student concerned to know what taxonomy has to offer as a discipline, it provides a stimulating and challenging introduction and guide. In this last connexion, it is gratifying to know that the authors are each to be concerned with new postgraduate courses in taxonomy in their respective universities, Edinburgh and Liverpool; with this text, their students should have a flying start.

Production is excellent, and the price, especially of the paper-back version, low enough to ensure that the volume, massive though it is, will have the circulation it deserves.

J. Heslop-Harrison

CLASSICAL PEDOLOGY

Treatise on Soil Science

By K. D. Glinka. Fourth (posthumous) edition, revised by the soil scientists of the Dokuchaev Soil Institute, Academy of Sciences of the U.S.S.R. Translated from the Russian by Prof. A. Gourevitch. Pp. v + 674. 126*s*.

Chemical Analysis of Soils

By K. K. Gedroits. Translated from the Russian by B. Toker and J. Schmorak. Pp. v + 602. 126*s*.

(Jerusalem: Israel Program for Scientific Translations; London: Oldbourne Press, 1963.)

GLINKA'S *Treatise on Soil Science* is one of the classics in the literature of pedology, and as such its translation into English must be welcomed.

Bibliographical and other material omitted from the third edition was restored in the latest Russian edition, but even so, such references as "cf. objections by Borggreve, by Wollny, by Dokuchaev" are common, and the book suffers from the incomplete documentation so common in Russian works on soil science.

The fourth edition was published in 1931—about the time that the application of X-ray diffraction to the investigation of soils overthrew many of the views then held in soil science; it follows that the first half of the book, which deals with "Soil Formation and General Properties of Soils", has little more than historical interest to-day. The chief value of the book lies in the section on "Soil Types and Soil Geography", which contains definitive descriptions of the great world groups.

Glinka makes no concessions to the novice; names of soil types are introduced without definition, and even in the chapter devoted to a particular soil type it is usually necessary to read most of the chapter before finding a passing reference to the soil's distinguishing characteristics. As in much present-day literature on soil, most of the information is given in the form of profile descriptions, which even dedicated specialists appear to find hard to follow. It would be a great help to the reader if a statement of the significant features of a profile were appended.

Glinka's essentially descriptive approach to the subject is exemplified by the statement on p. 170 "... one should not forget that the main task resides in the elucidation of the process which resulted in the formation of any given soil type...". One can only commend this, but the paragraph continues: "Laboratory research should be carried out in such a way as to disclose the loss and gains of each of the several horizons ... each and every horizon in the soil profile must be studied separately and its properties compared with those of the parent rock". Laboratory research is thus considered as no more than the detection of gains and losses, but the fact remains that one has done no more than define the problem by establishing that translocation has occurred. It is no criticism of Glinka's book to say that at present we must ask how and why translocation takes place; when we ask this question, the extent of our ignorance of soil genetics is all too apparent.

Just as in the development of the older sciences, pedology has reached the stage at which the descriptive approach initiated by Dokuchaev, and developed so ably by the Russian school, needs to be supplemented by experimental investigation of the fundamentals of soil-forming processes.

Units are often omitted from tables of analytical data, and the basis on which percentages are calculated is not always specified. The table on p. 142 contains a typographical error carried over from the Russian edition, as well as several minor errors in calculation. The translator directs attention to several similar errors in the Russian version.

Despite a slightly un-English syntax the translation reads smoothly, although the word 'chemism', which is used throughout the book, caused some hesitation; it seems to mean "chemical composition-cum-chemical properties". Misprints are few and, with the exception of the omission of the latter part of a sentence on p. 402, do not obscure the meaning.

Gedroits's *Chemical Analysis of Soils* must have been a very good book in 1932 when it was last re-edited, but its value to-day is questionable. About one-third of the book consists of a supplement of newer methods compiled after the death of Gedroits, and which gives references up to about 1953. However, apart from descriptions of the use of some Russian optical equipment, the supplement contains little that is not already available in the literature.

Gedroits's original section is characterized by an extremely thoughtful approach and he emphasizes the need for selecting the method most appropriate for the particular purpose. For this reason the book has some value as background reading, but it is unlikely to find much use on the bench of the practising analyst.

C. Bloomfield

PHARMACEUTICAL ANALYSIS

The Quantitative Analysis of Drugs

By Dr. D. C. Garratt, assisted by Dr. L. Brealey, C. A. Johnson, K. L. Smith and G. Sykes. Third edition. Pp. xiii + 925. (London: Chapman and Hall, Ltd., 1964.) 126*s*. net.

THE appearance of a revised edition of this hardy perennial of the analytical field is an event that will be welcomed by all practising pharmaceutical analysts. On this occasion Dr. Garratt has been assisted in the marathon task by a team of specialist colleagues and the result is one that must bring satisfaction to readers and authors alike. The last revision of the book appeared in 1955, and the fact that the authors have found it necessary to increase the size of the present volume by some 250 pages reflects the rapid growth in complexity of the subject over this period.

The manner of presentation of material remains the same as in previous editions. Drugs are dealt with by means of monographs arranged in alphabetical order, except, in cases such as antibiotics, steroids, sugars, sulphonamides, etc., where the similarities of the analytical methods used make group treatment the logical mode of presentation.

Each monograph commences with a brief introduction outlining the principle on which the assay of the drug is based, and is followed by a detailed description of a recommended method. The limitations of the method are then discussed together with any modifications known to be necessary to cater for specific forms of interference. The monographs are studded with a multitude of critical observations and tips culled from the author's wide personal experience over many years as a practising analyst, and these are among the most valuable facets of the book.

Methods described in the previous volume that have been superseded in the interval between revisions have been ruthlessly discarded and replaced by their modern counterparts, as evidenced by the wider use of physical techniques such as ultra-violet and infra-red absorption and the various forms of spectroscopy and chromatography. The author makes reference to phase solubility analysis, electrophoresis and polarography and predicts their increasing application in pharmaceutical analysis. In this I am sure he is correct and to these could usefully be added nuclear magnetic resonance and mass spectrometry.

Much absorbing information is included in the twenty-one appendixes to the volume, many of which make their appearance for the first time. These range from practical hints on the elimination of emulsions during solvent extraction with immiscible liquids; a very real problem in the analysis of galenical preparations such as tinctures of *Hyocyamus* and *Cephaelis ipecacuanha*, to brief monographs on the application of infra-red spectroscopy and gas-liquid chromatography in quantitative analysis. These latter are not intended to be comprehensive treatments but include sufficient references to enable the interested reader to explore the subjects further.

The authors are to be congratulated on a formidable undertaking carried to a successful conclusion, and I am sure that the present volume will achieve a wide distribution among all those engaged in the field of pharmaceutical analysis.

A. HOLBROOK

ASTRONOMY, PRESENT AND PAST

Watchers of the Skies

An informal History of Astronomy from Babylon to the Space Age. By Willy Ley. Pp. xiii + 528. (London: Sidgwick and Jackson, Ltd., 1964.) 45*s*.

MANY histories of astronomy have been published during the past few years. All have followed much the same pattern; some have been poor, some mediocre, and a few good. This new book by Willy Ley is, however, distinctly different. Written in what the author evidently regards as an informal style, it nevertheless imparts a great deal of information not found in other books of its kind.

Part 1, "A Science Grows Up", describes the beginnings of astronomy, and its gradual development up to the eighteenth century. Without pretending to be exhaustive it covers a wide field, and gives the reader an excellent idea of how astronomy changed from casual star-gazing into an exact science. Part 2 deals with "The Solar System", and represents the major part of the book; a chapter is devoted to each planet, not forgetting the mythical Vulcan, and many little-known facts are brought out. The final section of the book, "Approximate Infinity", is briefer, and deals with developments in stellar astronomy and cosmology.

The author owes much to his writing style, which is remarkably clear and lucid throughout. Though the book is essentially popular, and can scarcely fail to interest the beginner, it is also valuable to the serious student; evidently an immense amount of work has gone into its compilation. There are useful references, together with a general bibliography, while the line drawings are very adequate. Wisely, Ley has resisted the temptation to include the usual spectacular but hackneyed photographs.

So far as the Solar System is concerned, the historical account could scarcely be bettered. It seems, therefore, to be a pity that the author has not dealt with stellar investigations in equal detail. His account is first-class so far as it goes, and suffers only in comparison with the treatment of the planets; to extend it would mean making the book very long, but such a course would be worthwhile, despite the inevitable difficulties of production. The account of theories of stellar evolution is, for example, somewhat sketchy, while radio astronomy is relegated to a brief note in the appendix.

As the author has stressed in his foreword, no attempt has been made to write a history which is exhaustive in every field of astronomy. The book, as it stands, is far superior to any of its predecessors. The criticisms are made here only because there has long been a need for a standard work on historical astronomy, and *Watchers of the Skies* so nearly fulfils all the requirements. A suitable extension of the astrophysical section would set the book in a class of its own, and there should be every opportunity for this, since future editions will certainly be called for.

The text is extremely accurate. There are a few minor misprints, such as 'Encke' for 'Hencke' on p. 321, and one or two slips; on p. 347, for example, it should be made clear that the 'South Tropical Disturbance' on Jupiter no longer exists (it has not been observed since 1941), while E. J. Reese, who has directed particular attention to the surface features of Jupiter, is American and not British. In Part 1 it is stated that Newton invented the reflecting telescope, but there is no mention of Gregory, who had proposed the principle earlier; and on p. 461 it is said that most galaxies are spiral in form, whereas in fact spirals seem to be in the minority. Errors are, however, very few and far between.

It is always easy to suggest improvements to a book, but it is safe to say that the reader who is anxious to learn something about the story of astronomy cannot do better than study Ley's account. Serious students will benefit equally, since they will find many facts not readily available elsewhere in collected form.

PATRICK MOORE

SOVIET AMMONIA MASER RESEARCH

Soviet Maser Research

(Transactions (Trudy) of the P.N. Lebedev Physics Institute, Vol. xxi.) Edited by Acad. D. V. Skobel'tsyn. Authorized translation from the Russian. Pp. 186. (New York: Consultants Bureau, 1964.) 27.50 dollars.

IN 1954, groups working at the Lebedev Institute and at Columbia University announced the first working models of the maser; both used a microwave inversion transition in the ammonia molecule. This paperbound translation of a volume of the *Transactions* of the Lebedev Institute contains four papers which summarize subsequent work at the Institute on the ammonia maser, mainly in connexion with its use as a stable oscillator and standard of frequency. The title of the English translation is unfortunate, as it could be taken to imply a far wider scope for the contents than this very restricted field. A bibliography lists papers published by members of the Oscillation Laboratory of the Physics Institute of the Academy of Sciences from 1935 to 1961; these papers have only an incidental connexion with masers, and cover subjects as diverse as electron paramagnetic resonance and the flight orientation of birds.

Under the title "Characteristics of Masers" G. M. Strakhovskii and I. V. Cheremiskin report experimental work on the relative stability and reproducibility of the oscillation frequency of a maser using the 3,3 line of $^{14}NH_3$, and its dependence on various operating parameters. N. G. Basov, V. S. Zuev and K. K. Svidzinskii describe similar work on the ND_3 maser, which produces a frequency near 1,600 Mc/s, significantly lower than that of the NH_3 maser which operates in the region of 24,000 Mc/s. Theoretical aspects of the frequency characteristics of the ammonia maser are considered by A. N. Oraevskii, who includes proposals for the use of oppositely directed beams and the reduction of beam velocity to improve the performance of the maser. The fourth paper, by K. K. Svidzinskii, is a comprehensive theoretical treatment of a subject related to the field of molecular beam maser research: the hyperfine structure of the rotational spectra of molecules.

The ammonia maser as a reproducible frequency source has been superseded in turn by the cæsium atomic beam standard and by the hydrogen maser. As a low-noise amplifier the solid-state maser is more practicable and versatile. In spite of the dwindling interest in the ammonia maser itself there is a good deal of instructive material in these translations, and the bibliography may reveal papers the existence of which could not previously be easily discovered. J. H. SANDERS

ELECTRON AND VACUUM PHYSICS IN EASTERN EUROPE

Proceedings of the Symposium on Electron and Vacuum Physics, Hungary, 1962

Chief Editor: Ernö Winter. Pp. 506. (Budapest: Akadémiai Kiadó, Publishing House of the Hungarian Academy of Sciences, 1963.) 11 dollars.

IN the present-day unhappy division of Europe into the Western and Eastern spheres of influence, it is always of interest to gain knowledge of scientific activity in Eastern Europe. In this respect, this excellently printed volume is valuable in presenting fifty-five papers read at the Budapest Conference in 1962, which was devoted to electron and ion physics and optics, vacuum physics and techniques and gaseous discharges. All except six of the papers are from Hungary, Roumania, Poland, Czechoslovakia and East Germany, with the majority from the first of these countries, but with virtually no influence (except in references) from the U.S.S.R. Admittedly six of the papers are in the Russian language, but they are chiefly by Czechs, the remaining forty-nine are in English or German with the exception of that, in French, by M. Degras (from Saclay) on the investigation of sorption by electron bombardment. Moreover, the many references collected in the Eastern European papers are primarily concerned with American, British and German work. Indeed, two factors are noteworthy: the apparently small influence from the U.S.S.R. in this field of activity and the indications that the Eastern European countries suffer a paucity of modern scientific equipment.

The direct British contribution is small and represented by papers from L. Holland, on surface contamination in vacuum evaporation systems, and by D. Gabor, on gas discharge work arising out of his experiments on thermionic generators. The well-known names of D. Alpert from the United States and P. Redhead from Canada appear, but otherwise the influence is dominantly Hungarian.

As the content of the papers of the few authors from the West is more readily available in recent American and British journals, the chief interest here is to survey briefly the topics covered within the papers from Eastern Europe. Electron and ion dynamics and optics are well represented, including two theoretical papers on quadrupole mass filters, one in Russian by C. J. Javor and a second in German by G. Otto. Among the papers on mass spectrometers is one by K. András, A. Dallos and J. Erdélyi in German, giving preliminary details of a new type of mass spectrometer, in which the ions move in spiral trajectories and selection is made at a specific angle of rotation in the track. Field emission cathodes and microscopes are clearly popular research topics, as is also secondary electron emission, particularly from the theoretical point of view. Other topics include oxide-coated, cermet and hollow cathodes, cæsium alloy photocathodes, conduction in gases including cæsium plasma, breakdown initiation and Penning discharges. As in Western Europe, investigations of gas sorption on filaments appear and the omegatron is a popular research tool for gas analysis observations, but one wonders whether the many papers published on the vagaries of this instrument might not eventually condemn it as a commercial device compared with the miniature mass spectrometer of the deflexion type. The hot-cathode ionization gauge in relation to ultra-high vacuum measurement is the subject of four papers, including one giving details by C. Brieman and R. Leyniers in English on a transistorized power supply for emission regulation. One paper on a 2-kW experimental electron-beam welder appears in English by E. Fóti and one on vacuum-tight windows for infra-red radiation detectors.

This volume is chiefly of use to the scientist engaged with research on electron tubes; it contains little of vital interest to the vacuum physicist able to consult the much vaster Western scientific literature. Perhaps one should be cautious here, however, after reading in German the opening paper by E. Winter which surveys the Hungarian research results in the fields of electron and vacuum physics within the period 1926–50, because he claims that several techniques in electron physics have originated in Hungary. Though this volume is unlikely to have much influence in Britain and America, it is nevertheless warmly welcomed as a record of research in countries with a growing scientific tradition. The excellence of the English used in many of the papers by Hungarian authors is, moreover, a tribute to their linguistic powers and to the first-class editorial work in preparing this book. J. YARWOOD

'OLD NICK'S' METAL

Nickel: an Historical Review

By F. B. Howard-White. Pp. xiii+350. (London: Methuen and Co., Ltd., 1963.) 45*s*.

THIS is no ordinary historical review, in the sense of scholarly detachment, but a man writing on the subject of his working life. There is perhaps a shadow of 'Pygmalion' in such devotion to one grey metal of less universal application than iron and of much inferior appearance to chromium. Nevertheless, nickel as an alloying element has played perhaps the most dominant part in the improvement of steels (based on iron), provided the ideal undercoating to chromium plate, and furnished the cutler with an amazingly good but cheaper substitute for silver. The author of this book concludes, in fact, with the attainment of manned space flight in a capsule sheathed in nickel-bearing materials.

The earliest known uses of nickel are the fortuitous occurrences in copper and bronze articles found in Antioch, Ur, and Kish, dating back some 3,500 years. The source of the material may be coincident with that of similar objects found in China. Undoubtedly, a favourite source of nickel was that of meteoric iron, and the word for iron used in Babylonia, Egypt, and Syria in ancient times signified 'heaven-sent'. Nickel was, therefore, a ubiquitous material long before it was isolated by Cronstedt in 1751. As almost every schoolboy knows, the name arose as a result of attempts to smelt the nickel-arsenide ore occurring in the Erzgebirge, and which was mistaken for copper ore. The association with 'Old Nick' arose partly because no copper resulted, partly by virtue of the arsenical fumes (injurious to health), and partly because the roasted material, required by local potters to colour their products, sometimes failed to do so.

The commercial exploitation of the metal provides a most fascinating story. The initial interest arose from the non-ferrous alloy known as German or nickel silver (known earlier to the Chinese as 'white copper'), and as demands increased, the quest for improved nickel ores spread farther, and the rich deposits in Canada and New Caledonia began to enter a phase of intense rivalry. The French source contained no copper or precious metals, and was comparatively easy to smelt, whereas the Canadian source required an economical process for the separation of copper and other metals. Needless to say, a method was found, relying principally on the immiscibility of two molten sulphide layers. Purification of the nickel became possible from the discovery of nickel carbonyl, and its development by Ludwig Mond.

The subsequent use of nickel in electro-plating, its incorporation into steel, particularly for armaments, and the development of new non-ferrous alloys based on reduction of the Canadian 'matte' containing copper, to give 'Monel' and a host of derivatives, created an unprecedented demand. (The First World War caused a trebling of production during a decade.) New alloys appeared with the discovery of so-called 'stainless' steel, and between the two World Wars, nickel became an alloying element in cast irons, and a constituent of many magnetic materials. Perhaps the most romantic story of many new uses for nickel is that of the gas turbine and later rocket engines.

The books contains some useful notes on each chapter, and five appendixes, the fifth being a key to the Annaberg Altarpiece by Hans Hesse, 1521, a reproduction of which forms the frontispiece. The style is easy to read; the author, as an engineer, pays full homage to the chemist and metallurgist, and provides an absorbing series of portraits of men in the industry. A professional historian could scarcely have done better. C. R. TOTTLE

A SHORT HISTORY OF METALS

A Hundred Years of Metallurgy

By W. H. Dennis. Pp. ix + 342. (London: Gerald Duckworth and Co., Ltd., 1963.) 35*s*. net.

DESPITE a history extending over some six or seven millenia, more progress has been made in metallurgy during the past century than in the whole period during which metals have been known to man. It is no easy task, therefore, to compress these into some 330 pages, and the skill with which this has been done and the ground covered reflect great credit on the author. The picture painted is, however, in the main concerned with that branch of the subject which deals with the extraction of the metals from the ores, and the subsequent processes to which they are subjected to render them fit for use are dealt with somewhat briefly.

In many cases, an essential preliminary to the actual smelting process is the removal of the waste material from the ore, and ore-dressing has assumed a greater importance as it has become necessary to utilize leaner ores; the flotation process and sintering are emphasized especially, so far as the latter is concerned, in connexion with iron and steel. Roasting is a necessary preliminary to the subsequent extraction of the metal in the case of many sulphide ores, and the introduction of the fluo-solid roaster in which the finely divided feed is held in suspension by a stream of gas is one of the more outstanding advances in this field.

The electro-magnetic discoveries of Faraday have had repercussions in two ways and, indeed, there are few better examples of the mutual interaction of discoveries in one field of knowledge on another. The demand of the electrical engineer for copper and aluminium as conductors and the fact that the electrical industry has become a major customer for lead and other metals have had immense economic influence on metallurgy, while the use of electric power in arc and induction melting has rendered possible techniques of which the metallurgist himself has taken full advantage. Hydrometallurgy—the process of recovering a metal by solvent action as, for example, in the cyanidation of gold and silver ores or in the Bayer process for the extraction of aluminium from bauxite—is then considered. After this general introduction the progress made in connexion with the production of iron and steel, the major non-ferrous metals, the 'newcomers' and the precious metals are dealt with in turn. A short chapter is devoted to subsequent shaping process, and the book ends with a very brief account of the fundamentally important question of metallography.

Within the limits which the author has been allowed this is done well, the descriptions are clear and the material well chosen. It is inevitable, however, in such a widespread survey that there are minor errors, one of which in a historical treatment may be mentioned. It is stated (p. 279) that the earliest separation of gold from silver was effected by the use of nitric acid. The earliest Greek coins were made from natural electrum containing up to around 30 per cent silver. It was not until the reign of Croesus in the middle of the sixth century B.C. that a pure gold currency was introduced—the method of removing the silver being still unknown, though it is not improbable that it may have been done by prolonged heating with sulphur or a sulphide. This would eliminate the silver as a molten silver sulphide slag: it was certainly long before nitric acid was available.

The author has done an excellent job of work, and his book maintains well the reputation of the series in which it appears. F. C. THOMPSON

SEMICONDUCTORS

Progress in Semiconductors

Vol. 7. Edited by Alan F. Gibson and Prof. R. E. Burgess. Pp. 238. (London: Heywood and Co., 1963.) 65*s*.

THE first and last of the four articles in this volume are by American authors, and the other two are by British; but there is little or no sign of this distinction in the presentations or styles of writing. Indeed, there is a marked similarity between the first two articles, on bismuth and bismuth telluride respectively, in that the best available data on physical properties are selected and used to test present-day theories of the band structure of each substance.

Some licence has been taken with the definition of a semiconductor in including the article on bismuth, but that strange semi-metal with its rare and even unique properties deserves attention. At low temperatures, the surface scattering of carriers is specular rather than diffuse, and several properties, notably magneto-resistance, which result from the application of a magnetic field show a periodicity in the reciprocal of field strength. For a substance the lattice of which departs so little from simple cubic, bismuth has many properties which are highly anisotropic and not easy to interpret.

Bismuth telluride is noteworthy because its figure of merit as a material for thermoelectric generation or refrigeration is among the highest recorded. Exact stoichiometry (Bi_2Te_3) in single crystals seems always to result in p-type conductivity; not until the tellurium content is increased to 63 per cent (atomic) is intrinsic behaviour noted. The article on this substance concentrates on the galvanomagnetic and thermoelectric properties and thermal conductivity, without neglecting the elastic constants and optical properties, and reports some hitherto unpublished measurements of specific heat.

The two elemental semiconductors, germanium and silicon, dominate the rest of the book. In the third article they are the vehicles for studies of the interactions of impurities with dislocations, a subject which has been attacked from several sides with some success even though some very obvious simplifications have been made in the models assumed. The elastic and electrical interactions and the kinetics of migration are briefly described before more detailed attention is directed to precipitation, particularly of aluminium in silicon crystals containing much oxygen ($\sim 10^{18}$ atoms cm^{-3})—which may be sited interstitially or be largely combined in the form of silica precipitates—and of some fast diffusers in both germanium and silicon. The role of carbon in silicon, only recently appreciated in this context, is not overlooked.

The fourth and longest article examines the effects of high hydrostatic pressures (10,000 kg cm^{-2} and upwards) on the electronic properties of the two elemental semiconductors and of one or two intermetallic compounds. Most interest has centred around the band structure, including, particularly, changes in the energy gap as deduced from measurements of resistivity and optical absorption, and the scattering of carriers as reflected in the drift mobility. The influence of pressure on the effects introduced by impurities, donors and acceptors and those giving rise to deep lying levels receives due attention. The authors do not fail to point out the more serious gaps in present knowledge: thus the pressure dependence of permittivity and refractive index deserve more attention and many measurements already made with temperature as a second variable have yet to be given satisfactory quantitative explanation.

Many physicists and materials scientists can profitably explore this volume despite its specialist appeal; they will find the descriptive portions of each article easy to absorb. J. R. TILLMAN

NEVANLINNA THEORY OF FUNCTIONS

Meromorphic Functions

By Prof. W. K. Hayman. (Oxford Mathematical Monographs.) Pp. xiv+191. (London: Oxford University Press, 1964.) 63*s*.

PROF. HAYMAN'S monograph deals with that part of the theory of functions of a complex variable which discusses the roots of an equation $f(z) = a$, where $f(z)$ is either regular in the whole plane (an integral function) or regular save for poles (a meromorphic function), with related results when the domain is the unit circle. The theory has a fairly long history, since it may be said to have begun with Picard's famous theorems, that if $f(z)$ is an integral function, $f(z) = a$ has roots for all values of a with at most one exception, and that if $f(z)$ is meromorphic, there cannot be more than two exceptional values of a. Hadamard developed the theory of integral functions, using the order, which is ρ if the maximum modulus on $|z| = r$ behaves like $\exp(r^\rho)$. The connexion between order of growth and zeros is crudely that the more zeros, the greater must be the order.

The modern theory, to which Hayman has himself made substantial contributions, arises almost entirely from the fundamental work of Rolf Nevanlinna, begun about 1924, described in Nevanlinna's 1929 tract in the Borel collection and in one of the Springer 'yellow-backs' in 1936. On the basis of Jensen's generalization of Poisson's formula, Nevanlinna derived his central 'characteristic function', T, which differs boundedly from a sum $m + N$, where N measures the number of times the function $f(z)$ takes the value a, and m measures the intensity of the approach of $f(z)$ to a; this is in fact the first fundamental theorem. The second asserts that in general N is the dominant term in the sum $m + N$. From a study of the properties of T, a host of special results can be deduced, such as Picard's theorems and extensions; for example, if $f_1(z)$, $f_2(z)$ assume 5 distinct values at the same points, they are identical (and 5 cannot be replaced by 4). The methods extend to results about the derivatives of $f(z)$.

A somewhat similar line of thought is due to Ahlfors, expressed in terms of lengths and areas in mappings on to a Riemann sphere; here the outstanding result so far appears to be Ahlfors' 'five islands' theorem. When the general theory is applied to functions meromorphic in the unit circle, it yields as special cases the famous theorems of Schottky, Landau, Bloch and Bohr.

As a lucid and connected account of recent work in this field, the book will be of immense value to the young research worker, since it appears that the methods are far from being exhausted, either in their power to afford new results or in co-ordinating a variety of special cases into a simpler and more general theory. The novice, however, might be well advised to acquaint himself with Nevanlinna's Borel tract as a prolegomenon to Hayman's masterly work, a work which will surely be the standard text in this field for the present generation.

T. A. A. BROADBENT

MODERN ALGEBRA: A POWERFUL ENGINEERING TOOL

Matrix Algebra for Electrical Engineers

By R. Braae. Pp. xi+162. (London: Sir Isaac Pitman and Sons, Ltd., 1963.) 30*s*.

NOW that matrix algebra is finding its way into sixth-form mathematics we can expect the next generation of electrical engineers to be fairly conversant with it by the time they are professionally qualified. Many of them know little to-day of its elegance and power, and find mathematical text-books, admirable as they are, faintly repellent. Such electrical engineers will find Mr. Braae's work clear, readable and interesting. He is himself an electrical engineer and has written with the peculiar needs and difficulties of his fellow engineers in mind.

The scope of the book is wider than the title suggests. The author's declared aim is the modest one of enabling a beginner to reach a standard where he can read engineering articles that use matrices without too much difficulty. Any reader who absorbs this text and tackles the many exercises scattered throughout the work should be in a position to 'originate' articles using matrices as well as read them.

In addition to the main subject of determinants and matrices some of the topics dealt with, and dealt with competently, are vectors and vector spaces, co-ordinate transformations, group theory, bilinear and quadratic forms, invariance, linear programming, applications to geometry and mechanics, linear networks, diakoptics (that is, the piece-wise solution of large systems, not to be confused with the partitioning of matrices), and an excellent final chapter on tensor analysis which takes the reader as far as covariant and intrinsic derivatives. Clearly the book is not about matrices alone but about their place in engineering mathematics and their relation to allied subjects, and the ground is prepared for a deeper study of tensors and topology. Since the book is designed for self-study there are many exercises and at the end of each chapter a set of problems for the reader to solve. There is also a good bibliography designed to guide readers with their further reading in the allied subjects and the applications.

In a disarming introduction, Mr. Braae disclaims any attempt at rigorous treatment, but in fact the treatment is more rigorous than electrical engineers need and willingly accept. The matter is presented so concisely that much ground is covered in the 160 pages of text. Yet the style is remarkably fluent and pleasant. It is certain that the author has a deep affection for mathematics. To him it is not just an engineering tool but a joy, and he seeks to arouse in his readers his own enthusiasm for a fascinating subject. His book can be warmly recommended to all electrical engineers.

W. J. GIBBS

NON-AQUEOUS SOLUBILITIES

Solubilities of Inorganic and Organic Compounds

Edited by Prof. H. Stephen and Dr. T. Stephen. Vol. 1: Binary Systems, Part 2. Pp. viii + 963–1933. (London and New York: Pergamon Press, 1963.) 250*s*. net.

THIS book is the English edition of a compilation of solubilities prepared under the direction of a panel of scientists appointed by the Soviet Academy of Sciences. It deals with non-aqueous binary mixtures and completes the first volume of a larger work, which will ultimately include ternary and multicomponent systems. It is a useful collection of data which is well arranged, for the most part in a tabular form, although graphical presentation of data is occasionally used. Molecular formulæ and name indexes for the whole of the first volume are provided and these are easy to use and enable the information to be readily located. Nomenclature is said to follow the recommendations of the International Union of Pure and Applied Chemistry and the indexing arrangement to be that of *Chemical Abstracts*.

This last-mentioned claim is not entirely true, in that elements in the inorganic section of the formula index are arranged by order of Periodic classification and not alphabetically. In addition to being indexed by name and by formula, the solubility tables are arranged according to the chemical formula of the component with the smaller number of carbon atoms. There are nearly 3,000 tables of solubilities in all and each table is provided with a reference to the original work from which the data were obtained. It is apparent from these references, of which there are more than 2,000, that the literature has been widely surveyed. The references to Russian literature are conveniently numbered 1–208. An examination of the references themselves is not without interest and reveals that about a third of them relate to work completed in 1914 or earlier. The very oldest reference is indeed old; it is a reference to the work of Gay-Lussac and is dated 1819. In contrast, only about one-tenth of the references relate to work completed since 1945. This is, of course, no criticism of the authors, who can only collect information from available sources, but when one considers the prodigious number of new compounds isolated or synthesized since 1945, this paucity of information on such a mundane property as solubility seems almost unbelievable and surely reflects an unsatisfactory situation.

On the debit side of this book, there are a number of omissions and misprints which although minor in themselves should not appear in a reference work and especially one at this price.

There are also some untranslated Russian words such as trace, insoluble, completely miscible, components, etc. These occur mostly in tables of figures and their presence is so obvious that it is difficult to see how they were missed during all the stages of preparation. Certain entries in the book relate to compounds existing in isomeric forms, and the nature of the isomer or mixture of isomers is not specified. Reference to the original journals, which were by no means readily accessible in all examples, revealed that in some cases additional information was available.

No doubt in the first edition of a work translated from Russian, errors can more easily occur than in other works. One hopes, however, that in future editions the various mistakes will be eliminated so as not to detract from an otherwise valuable collection.

The book will obviously not appeal to individuals, but it should prove a useful reference work for the library.

P. J. COOPER

TECHNOLOGY FOR SCHOOLS

Technology

Man remakes his World. Editorial Board: Dr. J. Bronowski, Sir Gerald Barry, James Fisher and Sir Julian Huxley. (The Macdonald Illustrated Library, Vol. 5.) Illustrated and designed by Hans Erni. Pp. 367. (London: Macdonald and Co. (Publishers), Ltd., 1963.) 55*s*. net.

THIS is a solid and well-produced book, worthy of the Verona printers who made it. In it are presented, in American style in two page units, the achievements of modern technology. The field which it ploughs is wide, even if the furrows are not deep. It is difficult to think of a technological subject which is not mentioned and illustrated in the book. It is an exciting book, and no doubt much of it will be relevant in five years time.

Technology is the fifth volume of a library of knowledge "for the family". It can be used as an encyclopædia or a background book for a fifth- or sixth-form pupil. To the older student of science it might be useful as a book of applications of his fundamental principles. The arts student should find it useful because it tells him of the forces which, whether he likes it or not, are shaping his environment. The illustrations, of which many are in colour, are of high quality and would make good teaching aids.

Apart from the possibility of the destruction of man by the atomic bomb, the tone of the book is optimistic. "Our planet," says the book, "will become what the British poet, William Blake, called 'a green and pleasant land'. Those who feel the need for a more exciting life will find it as pioneers and developers of the other planets in the solar system." The realistic critic, not to say the cynic, may feel that there are few signs of this at present. Perhaps it is not the fault of technology that it deals with means rather than ends, with techniques rather than values; but one might pause before this catalogue of human ingenuity and ponder on the increasing slaughter on the roads and of cancer of the lung, on high wages, leisure and adolescent crime, the starvation of a large part of the world, the transistor-set and noise nuisances, and the insidious tendencies to the erosion of human individuality, as a start.

It is understandable that the sales of this book will be greater in the United States than in Britain, but it is a pity that the English reader has to endure such spellings as "sulfa", "aluminum", "fiber", "center" and so on. Since communication theory is one of the subjects of the book, an intelligent sixth-former might ask why a common use of English for scientific communication in English speaking countries is not yet vouchsafed us!

W. L. SUMNER

POPULARIZING SCIENCE

"POPULARIZATION", Dr. Martin Green[1] has said, "is one of those words that goes round doing harm: it is one of the prime agents in a conspiracy to divide and enfeeble the modern mind: for it implies that the thing popularized has been reduced in value, and that the people reading it have been fobbed off with a substitute. It divides by implying that modern science, for instance, is so remote from the literary man's understanding that his idea of it is only half-true; and it enfeebles by implying that the only things we really know are a handful of specialities (if we are lucky enough to be specialists in something) and that the rest of our intellectual life is a game of blind-man's buff, if not an exercise in deliberate fraud".

Bad popularization is bad, of course, wherever one meets it: science is not singled out for special attention in this respect, although, no doubt, the education of journalists does not conduce to accurate reporting in this field. That scientists should make a scornful distinction between knowledge and half-truth is both natural and necessary, but those who persist in regarding popularization as an unprofessional activity do both science and culture a disservice. For, at its best, popularization of science can be an interpretative art-form in its own right, comparable perhaps to literary criticism, with a culturally valuable integrating function: or so Mr. Maurice Goldsmith (Science Information Service) claimed when the Scientific Publications Council met at the Ciba Foundation, London, on April 23 to discuss the subject. But Mr. Goldsmith sought for a word to replace 'popularization' in vain.

Prof. A. S. Parkes (Physiological Laboratory, Cambridge), introducing the subject, distinguished two possible meanings of popularization: making science popular as such among non-scientists, and making it intelligible to them. We undoubtedly have to make science popular, since scientific research is increasingly financed by public funds. Just as society now depends on science for its livelihood, so science depends on society for men and money, and both are impossible without public support. More complex are the questions of whether and how science can be made intelligible; the value of attempting to convey the changing detail which science accumulates is dubious, but it is important to communicate broad scientific ideas and more scientific and analytical ways of thinking. Of the several media available, Prof. Parkes commended the semi-specialist periodicals in particular, describing how he had been attracted to reproductive biology—as an academic pursuit—by an article in *Discovery* by Julian Huxley. Prof. Parkes imputed neither praise nor blame to Huxley for this, but he did draw a moral: that popular science is a great recruiting sergeant. This is important because the 'brain drain' is not only from the Old World to the New—it can also flow into unproductive forms of scholarship. It is interesting, however, that medicine, which receives the lion's share of publicity, is nevertheless among the last in the queue for public funds (although it is among the best provided for by private foundations, no doubt because of its high moral tone and philanthropic connotations). Perhaps familiarity breeds contempt, and maybe a certain mystique is necessary for respect.

From the early days of modern science there have been two major strands to the thread of popularization. Ever since Fontenelle (secretary to the French Academy of Sciences) wrote *Entretiens sur la pluralité des mondes* in 1686 there have been those who interpreted science to the public from within; and there has also been the equally honourable tradition of exposition from without, beginning perhaps with Voltaire's *Elements de la philosophie de Newton*, which appeared in 1738. More recently, specialization has added to these a third strand, that of interpreting biology to the physical scientist and vice versa, which has given rise to new and valuable channels of communication—*Endeavour*, *Scientific American* and Penguin *New Biology*, for example. For a while the popular and semi-popular press (such as *Discovery*) and the professional science writer—including eminent men like Waldemar Kaempfert—seemed likely to dominate the scene, interpreting science, as it were, from outside. But the newer mass media, broadcasting in sound and vision, have restored the possibility of immediate personal presentation by the scientists themselves, that was once confined to the limited audiences of the local learned societies and the annual meetings of the British Association.

Speaking from a personal point of view, Mr. Gordon Rattray Taylor (B.B.C. Television Science Service) took up the challenge on behalf of his particular mass medium. He distinguished five facets of popularization, namely, (1) news of recent advances in science; (2) knowledge of the great intellectual foundations of science, such as the theory of evolution or quantum theory; (3) appreciation of the scientific method and attitude; (4) the history of science; (5) the politics and economics of science—the way it is organized and financed. No doubt public finance necessitates popular support and may, indeed, impose an obligation on scientists to account for themselves, both individually and in general, before the public of which in all other respects they are themselves a part. But in the last analysis the justifications for popularizing science are the justifications for science itself: that it is an expedient and indeed necessary activity, that it is fun, and, most important of all, that it is a high intellectual enterprise and that any culture is flawed that is without insight into this great ferment of our age.

Mr. Rattray Taylor spoke of the philosophy and the technique of presenting science on television. At one time the approach had been to ask the scientist direct questions about science. There is perhaps a certain incongruity in asking the Astronomer Royal to discuss, say, the cause of the rainbow, and, although audience figures are not wholly reliable indexes of quality, such programmes did not attract wide acclaim. A more successful approach has been to take the television camera into the laboratory in order to show scientists as people with jobs and ways of living, rather as one might visit a factory and be fascinated by other men's lives and their environment, absorbing the general flavour without straining after detail. More recently, it has become clear that a very large section of the public seeks from the scientist not so much explanations as some sort of orientation towards his activities and attitudes and their place in the wider scheme of things, and programmes surveying whole areas of science have attracted audiences as large as ten million people.

Scientists are not infrequently rather inhibited in dealing with people—which may indeed have influenced them to go into science—and quite often poor speakers, but they are always to be preferred to professional actors in broadcast feature programmes because of their essential and total involvement. (Prof. Parkes thought they should be paid at Equity 'star' rates.)

There are, of course, considerable conceptual difficulties wrapped in the jargon of scientific discourse, and what constitutes an 'explanation' is itself a philosophically interesting question. As Mr. Rattray Taylor pointed out, Warren Weaver[2] has distinguished two modes of explanation: *horizontal explanation* in terms of familiar physical analogies (radio propagation in terms of waves on water), and *vertical explanation* by analysis into simpler but related concepts (radio propagation in terms of electromagnetic oscillations). Whether the vertical or horizontal mode is appropriate in any context depends partly on the level and aim of the explanation. The vertical mode is always involved at the level of quantification and is, therefore, often thought of as the scientific explanation. Horizontal explanation, on the other hand, provides imaginative insight and is often the best basis for popularization, but the scientist sometimes feels embarrassed to be asked to speak in these terms, as though he were betraying a trust. However, vertical explanation carried to its conclusion also arrives at a set of irreducible concepts, which then have themselves to be explained horizontally (for example, by reducing electromagnetism to 'forces' which are ultimately metaphors derived from muscular tensions). So Schon[3] argues that science advances by displacement of concepts from familiar to unfamiliar contexts, by what is essentially an appeal to metaphor. Scientific explanation thus depends on both horizontal and vertical components. Horizontal explanation is perfectly valid for relating the unfamiliar to the familiar, the unseen and conceptual to the visible and tangible. To some extent familiarity is a matter of bodily size and sensory acuity, and the social role of explanation is simply to relate unusual phenomena to common experience. It has been one of the great achievements of science to bring the mysterious and magical into the sphere of the rational and physical by this sort of process.

Colin A. Ronan (London) agreed that it is one of the functions of popularization to discourage magical thinking. It is a great tragedy that incomprehension so frequently breeds not respect, but fear, and one of the historical triumphs of science has been to cast out fear, as Halley did, for example, when he brought comets within the Newtonian scheme. Popularization helps not only to dispel fear and to undermine the power of charlatans, especially in medicine, but also to offer an alternative to the uncontrolled mythopoeic imagination which is characteristic of primitive thought[4].

The history of science affords a great window for popularization (though not perhaps on television, as Arthur Garratt reminded the Council, where the business of fancy dress and writing with feathers tends to obtrude), probably because it deals in people with problems rather than the problems *tout court*. The International Geophysical Year and now the International Biological Programme offer perfect opportunities to display science as a very human activity, a co-operative venture cutting across all the frontiers of tradition and politics. Here television comes into its own again.

The difficulties to be overcome in popularization are not only, or even mainly, the conceptual ones involved in 'explanation', or those which arise when the physical scientist dares to explain matters of biological moment and vice versa. They are frequently semantic. William Molyneux was perhaps a little optimistic when he wrote to Hans Sloane in 1697, "I hear Mr. Newton's *Phil. Nat. Prin. Math.* is out of press [print], and that he designs a 2nd Edition. Pray advise him to make it a little more plain to Readers not so well versed in Abstruse Mathematicks, a few Marginal Notes and references and Quotations will doe the business". But mathematics apart, ever since science abandoned the 'close, naked, natural' use of language exacted from the founder members of the Royal Society, and substituted the 'didactic deadpan' of modern usage, it has been the foremost task of popularizers simply to translate from the hieratic into the vernacular[5]. Mr. Ronan recommended clear thinking and plain speaking as a salutary discipline for scientists and writers alike.

At the same meeting the Scientific Publications Council elected a new chairman and executive committee as follows: *Chairman*, Dr. R. K. Callow (National Institute for Medical Research, Mill Hill), in succession to Prof. A. S. Parkes (Cambridge); *Committee*, Mr. A. L. Bacharach, Prof. N. F. Maclagan, Prof. J. Rotblat and Dr. C. C. N. Vass. Mr. A. V. S. de Reuck (Ciba Foundation, 41 Portland Place, London, W.1) was elected honorary secretary.

A NEW FOSSIL HUMAN POPULATION FROM THE WADI HALFA AREA, SUDAN

By DR. G. W. HEWES, H. IRWIN, M. PAPWORTH and A. SAXE

University of Colorado Nubian Expedition,
University of Colorado, Boulder

DURING 1962–63 the University of Colorado Nubian Expedition, participating in the international campaign to salvage ancient remains in that section of the Nile Valley to be flooded by the waters impounded by the new high dam at Aswân, reported the discovery of a fossil human mandible from a presumably Upper Palæolithic site about 650 m west of the Nile, opposite Wadi Halfa, Republic of the Sudan[1]. In early 1964 another site was investigated, 1·5 km farther west, and 2·5 km from the River, which has yielded the permineralized skeletal remains of 38 individuals, associated with fossil bones of large bovids, and a flint tool complex of Mesolithic character. The skeletal remains, while obviously *Homo sapiens*, have several strikingly robust 'primitive' features, and appear to belong to a hitherto undescribed North African physical type.

Traces of ancient human occupancy at this place, now designated Site 6*B*36, were noted in December 1962 by Hewes[2], who picked up a few worked flints, but failed to observe the human and animal bones which lay a hundred metres or so south of his traverse. In mid-January 1964, Irwin, of the 1963–64 season's party, discovered burials eroding on the surface along with abundant faunal remains (large mammals, birds, reptiles), flint artefacts and hearths. Excavations were begun soon afterwards by Papworth, Saxe and the Expedition's physical anthropologists, G. Armelagos, G. Ewing and D. Greene, who will prepare the detailed analysis of the skeletal materials. The first task was to determine whether the mineralized human remains were contemporaneous with the fossil animals, flints and hearths. Fluorine, uranium oxide and nitrogen tests of the human and animal bones are now being carried out at the British Museum (Natural History), although the evidence from the excavations suggests that there is no difference in time between the deposition of the faunal, artefactual and human remains. The total absence of pottery is also indicative of a date prior to 4000 B.C., since cultures using pottery are known to have been in existence along the Nile both to the north and south by that time[3]. Age-determination by carbon-14 may present difficulties, since suitable charcoal has not been recovered from the hearths, though there is burnt animal bone which may be usable.

The site is located at about 21° 57′ 28″ N., 31° 19′ 10″ E., with a military grid reference of 918900 N., 647500 E., on the 1 : 25,000 topographic map of the area[4]. The site surface lies 32–35 m above the present mean level of the Nile at Wadi Halfa, or 152–155 m above mean sea-level at Alexandria. It will be subject to eventual flooding from the waters impounded by the new High Dam at Aswân. The site extends 450 m north-west–south-east, and 300 m north-east–south-west, occupying a gently sloping desert plain north of a large wadi or dry wash. In several places this surface is cut by gullies and beds of clean white sand, and is veneered on its higher spots by gravels. According to K. Butzer[5], such gullying reflects local episodic rainfall as the increasingly dry climate replaced pluvial conditions which had prevailed during the late Pleistocene. Destructive rainstorms still occur in this region of usually zero precipitation, as W. Churchill, C. B. M. McBurney and H. Kees have described[6]. Beginning around 5000 B.C., a moister climate returned to Nubia for the next 2,500 years. When the wadi still carried water down to the Nile, it presumably supported a local gallery forest, and what is now the surrounding desert, totally devoid of vegetation, was a grassland, probably with brushy patches which are indicated by extensive fossil root-systems on what are now quite barren plains. The moisture and vegetation had led to soil formation, indicated by a layer of *terra rossa* up to 30 cm thick in places, in which artefacts, human burials, faunal remains and hearths occur *in situ*. This relict soil is now overlain by gravels and wind-drifted sand. The bovid bones also testify to a moister climate, since these large herbivores would have required sufficient pasture.

The edges of the gullies which cross the site and 'drain' toward the wadi are marked by coarse dark sand and lensed fine gravel, derived from the low sandstone-capped escarpment to the north, which reaches elevations of 165–176 m above sea-level. The central gully channels contain white sand, which also underlies the *terra rossa*, and in turn overlies an ancient grey-brown Nile silt. Some hearths have been cut by the gullies. The surface gravel seems to have resulted from sheet-erosion from farther up-slope, formed during sudden rainstorms which at rare intervals even now afflict this normally rainless region. On the old silt, which is at the surface east of the site, are numerous molluscan shells—of the snail *Cleopatra* and the bivalve *Corbicula*. The Columbia University Expedition obtained during 1961–62 carbon-14 dates from these shells of around 9000 B.C. (ref. 7).

When the skull fragments of the first burials were examined in the field laboratory, it was apparent that the ancient population at 6*B*36 differed sharply from later pre- and proto-historic Upper Nile Valley peoples, who do not seem to differ much from the modern inhabitants of Nubia. Detailed presentation of cranial and other measurements and morphological observations must await further laboratory study and the reconstruction of fragmentary skulls, but the outstanding physical features of the 6*B*36 population can already be described in general terms.

Burial 2, typical of those on the site, lay on its left side with legs flexed, hands close to the face, head to the west, and shallow grave. The upper parts of the skeleton had been somewhat eroded, damaging the skull. Some other burials were multiple, with two or more persons interred in the same grave. In Burial 11, the head had turned downward, preserving the facial mask almost completely (Figs. 1 and 2). Judging from the pelvis, this rugged, muscular skull belonged to a female. Compared with recent Nubian skulls of the past 2,500 years, from Meroitic, *X*-Group, Christian Nubian, and later times, the supra-orbital area is massive, the nasal root depressed, the molars thick and greatly expanded at their lower margins, the orbits rectanguloid and the cranial vault low. The mandible has wide ascending rami, which flare outward at the gonial angles; the chin is rounded rather than sharp, the symphysis high and thick. Yet this mandible is not the most massive; that of Burial 14 (Fig. 3) is more so, and has an even broader ascending ramus. The stature of the presumed female of Burial 11 has been estimated from long bones to be 160 cm. (5 ft. 3 in.). The crania intact enough to measure (and there are several in excellent condition) indicate that the population tended toward brachycephaly, but a definitive statement must be postponed until more of the skulls can be reassembled.

Pergamon Press Publications

Advances in Water Pollution Research

This important work in three volumes is the authoritative report of the proceedings of the First International Water Pollution Research Conference, held in London in September 1962

Volume 1 – Editor: **B.A.Southgate,** Director, Water Pollution Research Laboratory, Stevenage

Contents:

Biological extraction and accumulation in stream self-purification – C.J.Velz and J.J.Gannon; The oxygen régime and the processes of self-purification in reservoirs with retarded discharge – S.M.Drachev; The effect of the current on the composition of biocoenoses in flowing water streams – O.Jaag and H.Ambühl; Self-purification of fresh water streams as affected by temperature and by the content of oxygen, nitrogen and other substances – E.Leclerc; An electronic monitor system for river-quality surveillance and research – E.J.Cleary; An analog computer for oxygen sag calculations – J.G.W.Rennerfelt; The prediction of stream reaeration rates – M.A.Churchill, H.L.Elmore and R.A.Buckingham; The research program on the Mississippi river in the vicinity of Minneapolis and St. Paul – G. J. Schroepfer, M.L.Robins and R.H.Susag; Recovery and identification of organics in water – R.D.Hoak; Investigation of a small watercourse accidentally polluted by phenol compounds – H.Krombach and J.Barthel; Salmonellae in crude sewage effluent and sewage-polluted natural waters – J.H.McCoy; The role of aquatic actinomycetes in self-purification of fresh water streams – J.K.G.Silvey; Determination and charting of the waste load in a flowing stream – G.Müller-Neuhaus; The effect of heated effluents on fish – J.S.Alabaster; Effects of domestic and industrial discharges on the ecology of riffles in Midland streams – H.A.Hawkes; Some effects of plants and animals on the conditions in fresh-water streams with particular reference to their oxygen balance – R.W.Edwards.

352 pages

Volume 2 – Editor: **W.W.Eckenfelder,** Associate Professor of Civil Engineering, Manhattan College

Contents:

A study of purification by biological means – G.Brebion, S.Prat and J.Prat; Concentration effects in the biological oxidation of trade wastes – I.S.Wilson; Mechanism of gas absorption by turbulent liquids – W.E.Dobbins; The present state of purification of town sewage in the city of Moscow – N.M.Popova and O.T.Bolotina; Water reclamation, algal production and methane fermentation in waste ponds – W.J.Oswald, C.G.Golueke, R.C.Cooper, H.K.Gee and J.C.Bronson; The biological filtration of coal carbonization plant effluents – S.H.Jenkins, J.A.Slim and (the late) G.W.Cook; Methods for the removal of phosphorus and nitrogen from sewage plant effluents – G.A.Rohlich; Removal of biologically-resistant pollutants from waste waters by absorption – J.C.Morris and W.J.Weber, Jr.; Experimental studies on high-rate digestion of nightsoil – S.Iwai, A.Honda and Chin-Yuan Chuang; Nutrient requirements and biological solids accumulation in anaerobic digestion – R.E.Speece and P.L.McCarty; Flow patterns in a rectangular sewage sedimentation tank – R.F.Wills and C.Davis; Recent work on the treatment and dewatering of sewage sludge – J.D.Swanwick, F.W.Lussignea and R.C.Baskerville; Growth and endogenous phases in the oxidation of glucose – T.R.McWhorter and H.Heukelekian; Determination of the size of tanks for the aerobic and anaerobic degradation of organic wastes – F.Pöpel; Human enteric viruses in water: source, survival and removability – N.A.Clarke, G.Berg, P.W.Kabler and S.L.Chang; The use of ceramic sponges for high level waste disposal – C.W.Christenson, R.G.Thomas, W.H.Adams, E.B.Fowler and G.D.Kelly.

584 pages

Volume 3 – Editor: **E.A.Pearson,** Associate Professor of Sanitary Engineering, University of California

Contents:

Considerations on the siting of outfalls for the sea disposal of radioactive effluent in tidal waters – R.T.P.Whipple; Scientific parameters of marine waste discharge – H.F.Ludwig and B.Onodera; Marine dilution and inactivation of sewage – R.H.Thomas; The occurrence, effects and fate of oil polluting the sea – C.E.Zobell; Nearshore winds and currents of Guanabara state, Brazil – R.E.Selleck and E.C.Peixoto; Mixing and dispersion of wastes by wind and wave action – F.D.Masch; Mixing in the surf zone – T.F.W.Harris, J.M.Jordaan, W.R.McMurray, C.J.Verwey and F.P.Anderson; Effect of wind, tide and weather on nearshore ocean conditions – J.D.Parkhurst, W.E.Garrison and M.L.Whitt; Some physical and biological characteristics of open coastal waters and their relationship to waste discharge – R.B.Tibby and J.L.Barnard; Ecology of the rocky nearshore environment in southern California and possible influences of discharged wastes – W.J.North; Toxicity of copper and chromium in the marine environment – J.E.G.Raymont and J.Shields; Water pollution and Minamata disease – R.Kiyoura; The calculation of pollution of the Thames estuary by a theory of quantized mixing – W.S.Preddy and B.Webber; The mixing processes in a tidal estuary – K.F.Bowden; Photosynthetic oxygenation of a polluted estuary – G.H.J.Hull; Nitrogen transformations in a polluted estuary – L.Wilkinson; Chairmen's summaries – B.A.Southgate, W.W.Eckenfelder and E.A.Pearson; Abstract of comments – M.D.Hollis; Votes of thanks – O.Jaag and M.D.Hollis; Closing remarks – E.Leclerc.

NOW! A whole range of Fully Interchangeable, Accurate Thermistor Temperature Probes

The YSI '400 Series' THERMISTEMP Temperature Probes incorporate thermistors **manufactured** to follow the same resistance/temperature curve. These probes are of various configurations, for use in many different fields of temperature monitoring, from medical and pathological to industrial laboratories, in agriculture, food storage, and in industrial plant.

Readings are taken on the portable battery-operated YSI Telethermometers, of which there are five basic models. The Model 41 (illustrated) can take six probes, and fast, accurate comparative temperature measurements can be made by simply switching from channel to channel.

Write or phone today for full details of YSI Temperature Probes and Telethermometers.

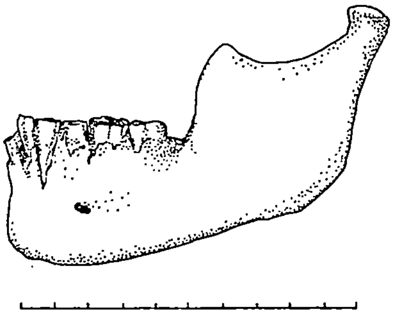

Fig. 3

The ancient population of 6*B*36 as known so far do not appear to be Bushmanoid, as has been claimed for the isolated Singa skull, found on the Blue Nile 320 km south of Khartoum[8], nor are they much like the Mesolithic Caucasoid populations of the Maghreb, such as Afalou bou-Rhummel, Taforalt, Mechta al-Arbi, and so on, who had flaring, massive jaws, short faces, but high cranial vaults and rather sharp chins[9]. If the 6*B*36 people were Negroid, they did not closely resemble either the man of Asselar, found in the western Sahara, or the inhabitants of the Early Khartoum site[10]. Surprisingly few skeletal remains have been reported for times prior to the immediate Predynastic Period in the Nile Valley[11]. Fossil human remains of apparent antiquity, but undated and undescribed, have been reported from Kau el-Kebir, south of Asyût, by Vignard in 1923, from Gebel Silsileh (a single frontal bone), from Kom Ombo Plain (also by Vignard), and from the east bank of the Nile near Wadi Halfa by the Columbia University Expedition during 1961–62. One or more of these finds may turn out to be approximately contemporaneous with the 6*B*36 population, and perhaps even physically similar to it.

Tools at 6*B*36 are mostly chipped uniface flint points and scrapers, amounting to about 1,000 specimens, plus about ten times that number of cores and scraps. The chipped implements were prepared from pebbles which occur in profusion on the higher terraces and hilltops. There are mullers or manos of reddish sandstone conglomerate, which takes a rough finish, and which must have contributed to rapid tooth wear among those who ate seed meal ground on them. Small flake points were made by a backing technique, leaving a steeply faced edge on one side, a sharp flake edge on the other, and part of the striking platform on the base. There are crescent flakes, 'geometric' flakes of microlithic proportions, side-scrapers, perforators, some real burins, and notched flakes which may have been used as shaft smoothers. The absence of bifacially flaked stemmed or concave-based projectile points, which are quite common in North Africa and the Sahara, and which occur in the Egyptian Neolithic–Copper Age sequence, is noteworthy. Ostrich egg-shell beads were also found.

Until more data are available, including radiocarbon dates from burnt bone on the site, and the results of more thorough analysis of the lithic industry, we can only make a guess at a date for Site 6*B*36, namely, about 6000 B.C. The Site was almost certainly occupied and used as a burial-place prior to 4000 B.C., or we should have found pottery. Site 6*B*27, which lies 1·5 km east, has yielded a carbon-14 date of 7312 ± 600 B.C., and its stone tools appear to represent a slightly earlier stage in the development of the local sequence. Site 6*B*36 implements are notably different from those on still another nearby ancient campsite, 6*B*29, which has been dated by carbon-14 at 13,150 ± 750 years. The radiocarbon tests were performed by Geochron Laboratory, Inc., Cambridge, Massachusetts.

The analysis of the local lithic tool sequence is being carried out by H. Irwin; the detailed site report for 6*B*36 is being prepared by A. Saxe. M. Papworth served as field director for the Expedition in the 1963–64 Season, with R. H. Lister and J. B. Wheat as senior research associates. G. W. Hewes was administrative director for the project. We thank Sayed T. H. Thabit, commissioner for archæology, Sudan Antiquities Service, and his staff, for assistance in the field. The work was supported by the U.S. Department of State under Public Law 480 Funds, and by U.S. National Science Foundation grants.

A NEW CHROMOSOME MODEL

By Dr. DEEPESH N. DE

Applied Botany Section, Indian Institute of Technology, Kharagpur,
S.E. Rly., India

SEVERAL attempts have been made to construct a workable model of chromosome based on the structure of DNA. Taylor[1] proposed a 'centipede' model in which the DNA molecules are arranged in a lateral fashion on a protein backbone. Later, Taylor[2] proposed another model in which DNA segments are attached to protein blocks on two sides. Schwartz[3] proposed the side-chain structure with DNA strands interlinked by protein for its integrity. Kaufmann and De[4] proposed that a chromosome is made of pairs of pairs of fine strands. Later, Steffensen[5] supported the structure. Recently, Cole[6] has proposed a complicated structure which needs large mechanical activity for replication and function. This model is based on a successive series of helical condensations of a linear thread composed of DNA segments covalently joined by short segments of either protein or specialized DNA. Unfortunately none of these models can explain all the established biochemical and cytological facts about a chromosome. Here I propose a simple model of the structural and functional unit of the chromosome, which conforms with all the cytological, genetical and biochemical data.

The proposed model is based on a large number of circumstantial and experimental evidence. Frey-Wyssling[7], examining the scattering of nucleic acid chains of chromosomes, concluded that the nucleic acid molecules are at right angles to the long axis of the chromonema. Mirsky and Ris[8] consider the backbone of the chromosome to be a protein framework. Removal of the DNA–histone complex by sodium chloride solution does not destroy the integrity of the chromosome, and they therefore consider the residual chromosome to be the basic unit. Enzyme digestion studies with DNase, RNase, pepsin and trypsin on animal chromosomes have led Kaufmann *et al.*[9,10] to conclude that, both structurally and functionally, the chromosomes of higher organisms represent an integrated fabric, in which histone and non-histone proteins combine with RNA and DNA. Wilkins[11] and Zubay and Doty[12] concluded that histone polypeptide chains are wrapped around both the small and the large grooves. From the works of Bloch and Godman[13], Rasch and Woodward[14] and others, it can be concluded that the DNA–histone ratio is maintained 1 : 1 throughout the cell cycle. With the aid of autoradiographic techniques, De[15] has shown that DNA and histone are synthesized concomitantly. Dounce *et al.*[16] have shown that residual proteins are firmly bound to DNA by covalent bonds at the end of DNA chains. Kirby and Frearson[17] also examined the DNA–protein bonds. On the degradation of DNA–protein they noticed that some glutamic acid, alanine and serine remained with the polynucleotide fragments. Steffensen[5] has indicated that divalent cations are bound to the chromosomes and they have a stabilizing effect on the chromosomes. Kaufmann and De[4] have shown from electron microscope examinations of chromosomes of *Tradescantia* that the most prominent unit of the fibres in the chromosomes is about 1000 Å in diameter. Gall[18] has shown that the diameter of the chromatid in the lampbrush chromosomes is about 500 Å. Gall[19] has also shown recently that the identifiable nuclear material from red blood cells of newt, human and grasshopper cells consists entirely of long fibres having a diameter of approximately 400–600 Å.

The proposed model is of a chromonema—the structural and functional unit of the chromosome. It follows the structural principle of Watson–Crick DNA model[20]. According to this model, the chromonema is made of two separate sub-units, each with a backbone of residual non-basic protein which is continuous along the length of the chromonema (Figs. 1 and 2). Several polypeptide chains are bound to each other by divalent cations Ca^{++}. The two protein backbones are so constituted they are unlike in some structural organization that restricts reunion of like strands when exchanges occur. The DNA segments are approximately at right angles to the length of the chromonema axis and are parallel to each other. For a given chromonema, the sequence of the DNA segments along the length of the chromonema is constant and species-specific. Each strand of the DNA duplex is attached by covalent bonds to one of the protein backbones at one end, the other end remaining free and the complementary strand to the other protein backbone in the same fashion. The DNA segments are wrapped around with histone. The length of the DNA segment across the chromonema could be in the order of 500–1000 Å, which may vary from species to species. The spacing between consecutive DNA–histone segments may not be constant, and the segments may be grouped in closer proximity to act as functional units. The chromonema is not structurally rigid and its dimensions would vary with degree of coiling and folding, and presence and absence of additional products of chromosomal activity. Nevertheless, the integrity is always maintained. The ionic environment would play a great part in coiling of the chromonema. In the proposed structure, RNA is not involved, but it may be associated with it as a metabolic product.

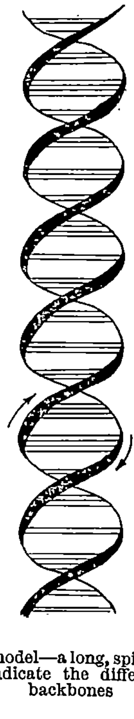

Fig. 1. General view of the model—a long, spirally coiled, double-stranded structure. The arrows indicate the difference between the protein backbones

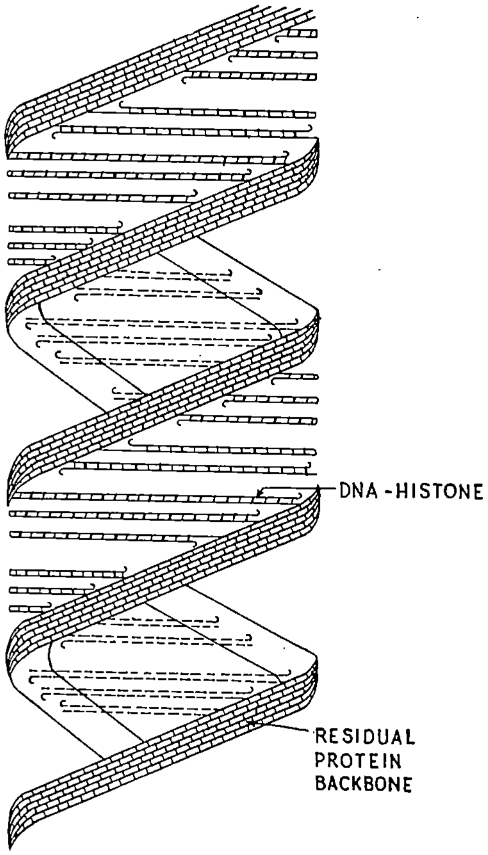

Fig. 2. Details of the model. DNA–histone segments are arranged like the rungs of a ladder and the protein backbone forms the two spines. Dark regions of the rungs represent the histone wrapped around DNA. Free ends of the DNA strands are exaggerated. The spacing between the consecutive DNA segments is not constant; nevertheless, there is a certain space between two consecutive segments. Two or more segments can form a group and act as a functional unit

The replication of the chromonema is like the semi-conservative replication mechanism of DNA molecule. The atomic identity of the sub-units of the chromonema is conserved, although effecting a permanent separation of the two sub-units from each other in course of replication. The replication begins with untwisting and gradual separation of the two sub-units from both ends of the

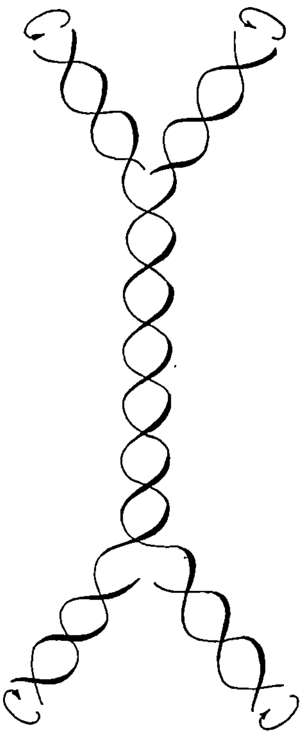

Fig. 3. A replicating chromonema, in which the upper arms rotate in the opposite direction of the lower arms. Replication and unwinding proceed *pari passu*

chromonema. The unwinding and replication proceed *pari passu*. Since the proposed model is supposed to replicate from both ends, the daughter chromonemata at one end will rotate clockwise and the other end anticlockwise (Fig. 3). The DNA segment also starts replication from both ends (Fig. 4). The free end of each strand of the DNA duplex untwists and separates and the complementary strand is progressively synthesized until it reaches its bound end. Finally, two hybrid molecules are produced. This is in perfect conformity with the results of Meselson and Stahl[21]. The histone chain may or may not separate from the parent DNA duplex, depending on whether the basic groups of a single histone chain simultaneously bind the phosphate groups of both the strands of the DNA duplex. Anyhow, after replication both the daughter DNA segments would be wrapped around with one old and one new histone protein. At this stage, small pieces of newly synthesized residual protein would be attached to the unbound end of the hybrid DNA. Joining together of these residual protein–DNA–histone complexes in 'zipper' fashion would progress from both ends of the chromonema until they meet each other at a place which may very well be the centromere as indicated by Taylor[22]. Thus the replication mechanism of the chromonema is in complete accord with the results of Taylor, Woods and Hughes[1].

Steffensen[5] has opined that any proposed mechanism of replication must satisfy at least the following restrictions: (1) labelled chromosome strands assort every other generation[1]; (2) DNA molecules are hybrid molecules[21]; (3) each fibril unit is organized in a progressive order of pairs of pairs[4]; (4) sister-chromatid exchanges are limited by the direction of the synthesis[23]; and (5) a mechanism of chromosome replication is compatible with DNA structure and synthesis[20]. The proposed model of chromonema structure and replication perfectly complies with all these restrictions.

The model is attractive in its simplicity and in its conformity with the general pattern of double-stranded coiled structure. It is likely that replication of the model would not need large mechanical activity. The model is expected to explain very easily almost all the cytological biochemical and genetical aspects of the chromosome.

The matrix is probably an artefact which is produced by extraneous material on the chromosome. The model fits with the observation that the end-view of a chromosome and fine fibres at the electron microscope level present a 'doughnut' or ring appearance, as has been shown by Kaufmann[24] and Kaufmann and De[4]. The euchromatin and heterochromatin regions of the chromosomes would probably have very little structural difference, but they probably differ in functional aspects. Optically observable chromomeres may be certain regions of the chromonema where DNA–histone segments are densely located and little more coiled. Cytologically observable centromeric granules are not different from chromomeres as electron microscopic studies have so far revealed no special structure. The centromeric granules could be visualized as a certain region of the chromonema where closely packed DNA segments synthesize a specific protein and/or where a special protein is attached to the residual protein, so that during spindle formation this protein couples up with the protein of the spindle.

The polytene structure of *Drosophila* salivary gland chromosomes are produced due to complete despiralization and increase in the length of the protein backbones of the numerous chromonemata without any loss in its integrity. One or more DNA segments of the chromonema give rise to band regions and the relatively wider spaces between the DNA segments to interband regions. This contention is supported by the fact that no DNA is observed in the interband regions as reported by Woods, Gay and Sengun[25] and Steffensen[5].

The induced and spontaneous chromosomal aberrations could be derived from breaking or loss of either one or both of the protein backbones of the proposed chromonema.

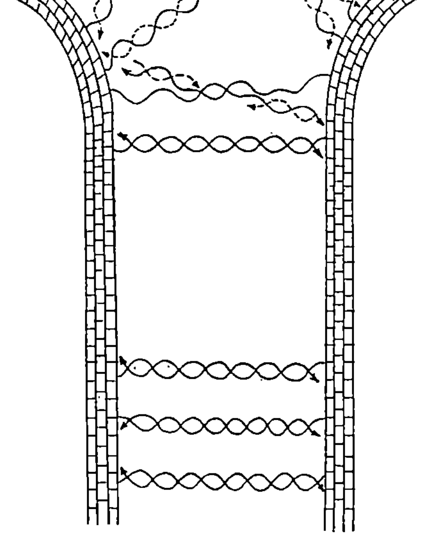

Fig. 4. Details of the replication mechanism. Histone round DNA segments are omitted for clarification. Arrows of the strands of DNA indicate free ends. Broken lines represent newly synthesized components. Each daughter chromonema is hybrid in both DNA and protein components

The breakage would not involve any damage to DNA segments. Wolff[26] has shown that protein synthesis is necessary for the rejoining of radiation-induced chromosome breaks. It has also been strongly suggested by Sharma and Sharma[27] that chemically induced chromosome breaks are chiefly due to hazards of protein synthesis. The mechanism of crossing-over could be easily explained by the proposed structure in which the protein backbone plays the vital part.

Mutation due to structural aberration is understood. The point mutations would involve change in the DNA segment. Any damage to DNA segment would cause intragenic mutation. According to Rhoades[28], in maize none of the mutations has been demonstrated by cytogenetic evidence to be an intragenic change. Nevertheless, position effect can be explained in the following way. A break of the protein backbone occurs between a particular sequence of DNA segments and the distal portion is rejoined to some chromonema in the chromosome complement. Even though the segments are not lost, the sequence is altered, causing alteration or blockade of gene function. The restoration of the segment-sequence restores normal gene function.

OBITUARY

Dr. G. W. Monier-Williams, O.B.E.

WITH the death of Dr. G. W. Monier-Williams one of the last links, if not the last, with the control of food and drug administration by the old Local Government Board has been severed.

Dr. Monier-Williams was born on April 17, 1881, and came of a well-known legal family, the effects of which were often displayed in his approach both in his chemical work and also in his dealings with those with whom he came in contact in his official capacity. He was educated at University College, Oxford, where he took a first class in chemistry in 1903, having spent part of the summer vacation in 1902 at Leipzig studying physical chemistry. From Oxford he went to Freiburg (1903–05), where he undertook research and obtained his Ph.D., after which he spent some weeks at Cognac studying distillation. He spent short periods as research chemist at the tar works of the Gas Light and Coke Company at Becton, and with A. Chaston Chapman, before commencing work in January 1909 as an assistant inspector of foods at the Local Government Board under Sir William Power, medical officer, and Dr. G. S. Buchanan, who was in charge of the newly formed food section.

Monier-Williams's name was first mentioned in the eighth report on the application of formaldehyde to meat, when he received a mention for having examined a formaldehyde preservative; but after this a steady stream of reports began to appear over his own name and dealt with such diverse topics as the colouring matters of flour, the artificial bleaching of flour, and preservatives. His report on the freezing-point test for the determination of added water in milk appeared in 1914 and contains about 100 references to the scientific literature—surely almost a record at that time. This work was interrupted by service during the First World War, when he went to France with the Expeditionary Force and transferred to the Special Brigade, Royal Engineers, on its formation in 1915, being appointed adjutant at the depot at Helfaut, France, where he remained for the remainder of the War, being awarded the M.C. and the O.B.E. for his services. Owing to his retiring nature he gave the impression that he was reserved, but with his tall and rather handsome appearance combined with his government experience he made an ideal officer for the post.

With the formation of the Ministry of Health the series of reports on foods was discontinued, and Monier-Williams read occasional papers to the Society of Public Analysts, though a few important and authoritative reports issued by the Ministry were written by him, notably those on the solubility of glazes and enamels used in cooking vessels, antimony in enamelled hollow-ware, the determination of benzoic acid in foods, the determination of sulphur dioxide in foods, the effect on foods of fumigation with hydrogen cyanide, and lead in food. After his retirement he wrote his well-known book on *Trace Elements in Food*, a volume which will remain a standard for many years, although the methods used for analysis are now being superseded. It is probably safe to say that few analysts have issued so many reports, which, though few in total number, will remain for so many years as the outstanding works on their particular subjects.

Apart from his work as an analyst and inspector of foods, Monier-Williams was a recognized authority at the Ministry, to whom public analysts or manufacturers could appeal for advice not merely on what was believed to be the legal interpretation of various food orders, but, even more important, what had been the underlying intention of the Ministry, when a particular item had been introduced into a statutory order. Public analysts had cause to be grateful to Monier-Williams and his colleague Mr. R. Butcher, for the investigation of any complaints which they might have in their dealings with local authorities. Although he served for three periods on the Council of the Royal Institute of Chemistry, and published articles in the *Journal of the Chemical Society* and the *Biochemical Journal*, it was to the Society of Public Analysts, now the Society for Analytical Chemistry, that he gave his greatest support, serving for no less than seven periods as a member of council or vice-president and finally, during 1945–46, as president. Monier-Williams was no mean artist and exhibited his landscapes at the Royal Academy and elsewhere; but with increasing deafness he tended to withdraw gradually from public life, much to the regret of his colleagues and friends. He was twice married, his first wife dying young, and our sympathy is extended to his widow and children, who survive him.

T. McLACHLAN

NEWS and VIEWS

Chairman of the Medical Research Council's Clinical Research Board: Sir Robert Platt

Sir Robert Platt, professor of medicine at the University of Manchester, has been appointed chairman of the Medical Research Council's Clinical Research Board, from October 1, in succession to Prof. E. J. Wayne. Sir Robert was a member of both the Medical Research Council and the Clinical Research Board from 1953 to 1957, and has been chairman of the Council's Committee for Research in General Practice since its formation in 1957. He is a member of the Central Health Services Council, and was chairman of the Health Departments' Working Party on Medical Staffing Structure in the Hospital Service. The Clinical Research Board was set up in October 1953, with the task of assisting the Medical Research Council in the promotion of clinical research on a national scale, and of advising the Health Departments on their scheme for decentralized research.

National Physical Laboratory, Aerodynamics Division: Dr. W. P. Jones

Dr. W. P. Jones, superintendent of the Aerodynamics Division of the National Physical Laboratory, has been appointed director of the NATO Advisory Group for Aerospace Research and Development. Dr. Jones joined the staff of the National Physical Laboratory in 1935 after a distinguished academic career. He graduated with first-class honours in mathematics at St. David's College, Lampeter, where he was a mathematical scholar from 1927 until 1930. He then went up to Oxford, as a senior student, after winning the Jodrell Mathematical Scholarship at the Queen's College. In 1932 he again graduated with first-class honours in mathematics but, instead of taking the usual course of working for a D.Phil. degree, he decided to read physics and passed his final examination in 1934 after only two years of special study of this subject. At the National Physical Laboratory he was attached to a group that specialized in research on flutter and vibration of aircraft under the leadership of the late Dr. R. A. Frazer. In 1946 Dr. Jones became the leader of the group, and in 1953 he succeeded Mr. A. Page as superintendent. During the past decade Dr. Jones has been concerned with the planning and development of new facilities for aerodynamic research and with the general supervision of the Division's research programme. The Division is now particularly well equipped for research on high-speed flows, including hypersonic and low-density flows and gas dynamics. Dr. Jones's published work has been mainly concerned with flutter and the theory of airflow over oscillating surfaces. He was awarded a D.Sc. by the University of Oxford in 1953, and in the following year he was elected Fellow of the Royal Aeronautical Society and also of the American Institute of Aeronautics and Astronautics. Dr. Jones has served on the Aeronautical Research Council of the Ministry of Aviation and on many of its committees and sub-committees. He is also a member of the International Advisory Committee on Rarefied Aerodynamics. In 1960 he was elected by the Massachusetts Institute of Technology to the Jerome Clarke Hunsaker visiting professorship for that academic year, and gave the 1961 Minta Martin Lecture sponsored by the Institute of Aerospace Sciences. In 1962 he delivered the Lanchester Memorial Lecture to the Royal Aeronautical Society.

Dr. R. C. Pankhurst

Dr. R. C. Pankhurst has been appointed to succeed Dr. Jones. After graduating with honours in physics in 1937 at the Imperial College of Science and Technology, where he held a Royal Scholarship, Dr. Pankhurst spent two years on research in molecular spectroscopy, particularly the emission spectrum of sodium hydride, in the Astrophysics Department of the College. A by-product of this work was the discovery of a highly complex band-spectrum due in part to the triatomic molecule SiO_2: this was of particular interest as the spectra of very few polyatomic molecules had been obtained in emission. He became interested in aerodynamics through spending a summer vacation at the Royal Aircraft Establishment, and joined the Aerodynamics Division of the National Physical Laboratory in 1939. During the Second World War he was engaged in theoretical work on the design and performance of the propellers for high-speed aircraft, under the guidance of the late Mr. C. N. H. Lock, and also carried out extensive wind-tunnel experiments on the aerodynamic performance of contra-rotating propellers. After the War, Dr. Pankhurst worked on the characteristics of aerofoils in two-dimensional flow, and became an authority on boundary-layer control, including its application to the reduction of aerofoil drag and the increase of maximum lift. Other noteworthy contributions in this field were wind-tunnel experiments (with Dr. B. Thwaites) on the flow with circulation around a porous circular cylinder. He has also maintained particular interest in experimental methods in fluid dynamics. For several years he has been leading a group concerned with (1) aerodynamic problems of vertical take-off and landing and the interaction of jets with surrounding streams; (2) flow laminarization with application to slender-delta wings; and (3) the study of turbulence in jets and boundary-layers with special reference to the mechanism of the production of aerodynamic noise. Dr. Pankhurst was elected a Fellow of the Royal Aeronautical Society in 1957. He is a member of several committees of the Aeronautical Research Council and was formerly associated with the Commonwealth Advisory Aeronautical Research Council, to which he made valuable contributions during its formative years.

Applied Mathematics in the University of Reading: Prof. J. N. Hunt

Dr. J. N. Hunt has been appointed to the newly instituted chair of applied mathematics in the University of Reading. Dr. Hunt, who is thirty-six years of age, after serving for two years as a Royal Air Force instructor, joined the Imperial College of Science and Technology, London, where he obtained, in 1950, a first-class honours degree in mathematics and, in 1952, a Ph.D. degree working under Prof. A. T. Price on the mathematical theory of gravity waves of finite amplitude in deep and in shallow water. During 1952–55 he held the post of scientific officer at the Department of Scientific and Industrial Research Hydraulics Research Station, Wallingford, where he worked on problems in hydraulics, such as viscous wave damping, beach erosion, tidal currents and storm-surges in the Thames estuary. He then transferred to the Atomic Weapons Research Establishment, Aldermaston, where for three years he worked on compressible flow, atmospheric oscillations, and on numerical computations connected with various models of the Earth's atmosphere. He spent the session 1958–59 as associate professor at the Georgia Institute of Technology, Atlanta, Georgia, working on wave propagation over a permeable surface. In 1959 he was appointed lecturer in mathematics and later reader in physical oceanography at the Imperial College of Science and Technology. Most of Dr. Hunt's published work has been connected with waves, either in water or in air, and deals with damping, sedimentation and mass transport, turbulence, instability, wind or currents. He has published a text-book on incompressible fluid dynamics and is working on a book on gravity wave theory and its engineering applications. He will take up his duties on October 1.

U.S. National Science Foundation Division of Engineering

A DIVISION of Engineering has been established by the U.S. National Science Foundation. Dr. John M. Ide, formerly director of the SACLANT Antisubmarine Warfare Research Centre, La Spezia, Italy, has been appointed director of the new Division.

Engineering research supported by the National Science Foundation has brought all the traditional disciplines of science to bear on technical problems. Not limited to the physical sciences, although it has historically had most connexion with them, engineering research has involved biology or the social sciences. Hitherto, basic research in engineering has been supported within the Foundation by the Engineering Section of the Division of Mathematical, Physical and Engineering Sciences. Engineering now becomes the fourth research Division, the other three being the renamed Division of Mathematical and Physical Sciences, the Division of Biological and Medical Sciences and the Division of Social Sciences.

Engineering research eligible for support by the National Science Foundation will have to be of a true scientific nature and not routine engineering practice. Examples of the types of engineering research that may be supported are: the development of principles and techniques in systems engineering design; interdisciplinary research related to such matters as biomedical engineering, transportation, urban planning, fire prevention, etc.; the development of principles of generation and control of energy systems and information systems; the analysis and synthesis of processes and systems which contribute to mastery of the environment.

Research supported by the National Science Foundation in the engineering sciences for the fiscal year 1963 totalled nearly 12 million dollars, through approximately 290 grants; in 1962 it was 9 million dollars through about 240 grants. During the fiscal year ending June 30, 1964, the Foundation granted approximately 13 million dollars for basic research in engineering.

Universities of Manchester and Liverpool Joint Research Reactor

THE research reactor which was built for the universities of Manchester and Liverpool at Risley, near Warrington, with a grant of £350,000 from the Department of Scientific and Industrial Research, became critical on July 7. The reactor will be used for postgraduate study and research, in the fields of nuclear engineering, radiochemistry and neutron and solid-state physics, mainly by workers from the two universities, although facilities will be made available to other universities and technical colleges in the north-west. It will also provide valuable facilities for the production of short-lived isotopes which are not at present available in the north of England. The reactor is based on an American design which has been considerably modified in order to raise the power from 10 kW to 100 kW and to increase its flexibility for experimental purposes. The main contractors for the reactor were Pye, Ltd., acting under licence from the American Machine and Foundry Co. of New York. The main contractors for the building were Harry Fairclough, Ltd., Warrington. The United Kingdom Atomic Energy Authority, acting as agents for the universities and the Department of Scientific and Industrial Research, placed contracts for the manufacture and supervised construction of the reactor, associated buildings and services on the site purchased by the University of Manchester.

Employment of Graduates

THE eighteenth annual report of the Appointments Board of the Universities of Newcastle and Durham for the year 1962–63 (Pp. 18. Newcastle and Durham: The Universities, 1964) covers the last year of operation of the Durham University Appointments Board—the Appointments Board of the Federal University having been reconstituted under a new title, but for the time being continuing to be responsible for appointments work on behalf of students and graduates of the two new Universities. In reviewing the general employment situation of graduates in 1963, the report suggests that demand by the private sector of the economy was little, if anything, stronger than in 1962, although there appears to be no reason for thinking that an end is in sight to the shortage of mathematicians, physicists and engineers. The report, however, is very critical of the forecast in the report issued by the Advisory Council on Scientific Policy, *The Long-Term Demand for Scientific Manpower*, in 1961. It suggests that the forecast failed to foresee the imminent explosion of demand for teaching man-power and that it also took too much account of short-term recession in industrial demand. While taking note of explicit demand, it neglected inarticulate demand, and was too complacent about staffing schools with science specialists. It implied also that only a small, and perhaps comparatively unimportant, section of the scientific community needed a good mathematical background. The report insists that discussions of the problem of teaching man-power commonly neglect quality and deployment and concern themselves mainly with numbers. While opportunities for some science and engineering graduates became scarcer in 1962 and remained so until quite late in 1963, the difficulties largely arose because of inflexibility on the part of the graduates. There are signs of significant increase in industrial interest in the recruitment of biologists. The Board is watching with interest the progress of trends towards subject-specificity in employers' demands for graduates in non-technical subjects, and away from subject-specificity in fields where it is at present fairly uniformly assumed.

Political and Economic Affairs in France, 1959–64

A PAMPHLET issued by the Press and Information Service of the French Embassy gives a concise survey of political and economic affairs in France for the period 1959–64 (*A Survey of Political and Economic Affairs in France, 1959–1964*. Pp. 26. London: Ambassade de France, Service de Presse et d'Information, 1964). It covers first the political institutions and recent innovations, which have ended the instability of Government, the decolonization measures, including the Evian agreements and the measures taken in Black Africa and Madagascar, changes in economic and financial affairs, and in defence and foreign policy. The pamphlet is a distinct contribution to the understanding of the situation in France and the changes in French domestic and foreign policy.

Sound Radio in the Television Age

IN the sixth of the second series of Lunch-Time Lectures arranged by the British Broadcasting Corporation, "Sound Radio in the Television Age", which has recently been published, Mr. F. Gillard observes that while there are unmistakable signs that radio will continue to be a medium in wide and accepted currency, the form of survival is more important and significant than survival itself (Pp. 16. London: British Broadcasting Corporation, 1964). So long as sound radio continues to uphold the principles of public service, integrity, independence, fairness, impartiality, sense of taste and sense of purpose, it will continue to flourish and justly hold its head high among the mass media of our day. Nevertheless, there will be change, and flexibility is essential—broadcasting must be sensitive to new developments, particularly in education. Flexibility is also called for in the techniques of programme planning. As regards technical development, very high frequency, 'VHF', is undoubtedly the radio system of the future. The possibility of stereophonic broadcasting on some regular scheduled basis is just beginning to show above the horizon. Even to-day, some 6 million people who have no television depend entirely on sound for their broadcasting service, and the needs of this audience are as diverse as ever. Extensions which the British Broadcasting Corporation has in mind at present concern particularly the Light Programme and the Third Network. The Corporation also wishes to introduce a completely new service in a system of local broadcasting, but on this the Government has reserved its position. The Corporation has great faith in the potential of this new dimension of sound broadcasting. Administratively, the local stations would be part of its regional system.

Library Service in the Manchester Region

THE 111th annual report of the Libraries Committee of the City of Manchester covers the year ending March 31, 1963, in which issues from the lending libraries increased by 45,000, and from the reference libraries by some 120,000 (Pp. 36. Manchester: The Public Libraries, 1964). The Committee's plans for reorganizing the service have continued, but have fallen far behind the programme approved in January 1960. A feature of the year was the large number of visitors from educational establishments of all kinds and also from overseas. In the technical library, the number of readers increased to a new record of 830,000 and additions during the year brought the total stock to 101,000 volumes. The technical lending library's book stock now exceeds 19,000 volumes and more than 16,000 volumes were issued from the collection during the year, but the phenomenal issue from the patents library of the previous year decreased by some 5 per cent. The use made of the information services to firms and institutions throughout Britain continued to expand. The collection of technical translating dictionaries in all the major languages now exceeds 500 volumes.

A guide to some of the resources available in the technical library at the Central Library, Manchester, in addition to books has been published by the Libraries Committee (*What's Available in the Technical Library: a Guide to Some of the Resources in Addition to Books*. By F. R. Taylor. Second Edition. Pp. 29. Manchester: Libraries Committee. Available from the technical librarian, Central Library, 1964. 2*s*. 6*d*.). In it Mr. Taylor describes the whole range of resources in detail, and particularly the periodicals, periodical indexes and abstracts, periodical location guides, standards, atomic energy documents, trade catalogues, literature surveys, technical translating dictionaries, patents and micro-texts. Finally, Mr. Taylor explains the service that is offered to industry and the way in which the library forms an integral part of the national library network.

Termite Studies in Africa

A COLLOQUIUM on African termites was held at the Lovanium University, Leopoldville, during May 11–16 and was organized jointly by the University and Unesco. M. Michel Colin, Minister for Education, République du Congo, presided at the opening session. The attendance of delegates from abroad was facilitated by Unesco in arranging a meeting of the Termite Sub-committee of the Humid Tropics Research Programme in Leopoldville during the course of the colloquium. In the ten years which have passed since the founding of Lovanium, Prof. A. Bouillon has developed a large and active Department of Zoology, in which special attention has been directed to the investigation of the Isoptera, a group of insects well represented in the grounds of the University. In his opening address, Prof. Bouillon stressed the importance of termite investigations from both the scientific and the economic points of view, not only to the Congo but also to the Tropics as a whole. In the 22 papers presented by workers at Lovanium a wide range of interests was exhibited, covering taxonomy, morphology, social behaviour and ecology, with special reference to the large mound-building *Macrotermes natalensis*, a new species of *Cubitermes* making small mounds in grassland, and three species of the genus *Apicotermes*, the elegant subterranean nests of which are one of the marvels of insect architecture. Co-operation with workers in other departments of the University has resulted in interesting developments in techniques and apparatus for investigating termites; for example, the use of microanemometers to measure air-flow in mounds, the estimation of pterines and their possible role as regulators in the sexual cycle, and the application of pedological techniques to investigations of mounds. A number of papers were contributed by the visiting entomologists. The proceedings of the colloquium are in course of publication by the University in its series *Studia Universitas Lovanium*.

Stonehenge

STONEHENGE has always fascinated everyone who has visited the monument. Who made it and when and why was it erected ? The first two queries have now been answered by the archæologist with reasonable certainty, though to what extent, if any, Mycenæan architects helped in the erection remains doubtful. But the reasons why the building was put up are less certain; clearly it was not for fun. Years ago, Sir Norman Lockyer pointed out that the orientation of some of the stones made it clear that a line on the rising of the Sun at midsummer could be obtained, and that, therefore, the 'temple' was of the nature of a calendar. Such a purpose would, of course, be vital for an agricultural people, who would want to know when to sow their crops, etc. Articles on the subject by Prof. G. Hawkins have recently appeared in *Nature* (200, 306; 1963; and 202, 1258; 1964). At the same time, and seemingly independently, Mr. C. A. Newham has published a pamphlet on the same problem (*The Enigma of Stonehenge and its Astronomical and Geometrical Significance*. Pp. 42. Tadcaster: C. A. Newham, 5 Sedge Rise, 1964). Both agree that the 'priests' at Stonehenge were interested in the Moon as well as in the Sun at midsummer, but Mr. Newham goes further and brings the Pleiades into the picture. Many authorities, when writing about Stonehenge, refer to Diodorus, an author who was writing about 50 B.C. In one passage he is thought to be describing the monument, and he mentions the Metonic (19 year) cycle which does, of course, involve the Moon. Unfortunately, the exact original position of every stone cannot be determined with complete accuracy, and, as Mr. Newham points out, much of the work can be likened to trying to aim a gun when the back sights are defective. It is interesting to find two investigators working independently on this problem, and much information can be gained from both.

Applied Science and Technology in Japan

OF the *Memoirs* published periodically by the Faculty of Industrial Arts, Kyoto Technical University, Matsugasaki, Sakyoku, Kyoto, Japan, *Science and Technology* (12, December 1963) gives an impression of the versatility of the research work carried on in this important institution. This issue, entirely in English, contains six papers: measurement of fibre fineness by horizontal air-flow, by M. Uno, A. Shiomi and Y. Yanagawa; approximation theory of general thin elastic shells, by O. Matsuoka; autoxidation of alcohols and their reactivities, by S. Kato and F. Mashio; mineralogical study on the Brazilian aluminium phosphate ores, by T. Arimori and N. Yoshida; on the flow of flaming gases in the end-fired glass melting tank furnace, by K. Terada and M. Wakamatsu; and on the dynamic fatigue life and cracks of rubber vibration isolator. This particular *Memoir* is well printed, and the English translations are reasonably good, the papers, where appropriate, being illustrated with ample diagrams and reproductions of original photographs.

U.K. Central X-ray Library

The first central library of X-ray films in Britain is to be set up by the Faculty of Radiologists in London, with the aid of a grant from the Wellcome Trust. The object of the library is to gather in one place a wide range of X-ray studies of common and rare diseases, since recognition of an uncommon disease may depend on the knowledge gained from similar cases. Radiological techniques are of special importance in providing knowledge about the condition of inaccessible organs during life. A number of major advances in medical knowledge have already resulted from radiological investigations. In the past, clinicians and research workers investigating rare diseases have had to gather X-ray examples from different hospitals throughout Britain. The new central library will enable a quick comparison to be made of a cross-section of previous investigations of a particular disease. The Wellcome Trust was created by the will of the late Sir Henry S. Wellcome, who died in 1936. In the past six years it has made grants totalling more than £4 million for work in medical and allied sciences.

Nucleonic Instrument Modules

A new booklet which describes the Wells series of Nucleonic Instrument Modules is now available from EMI Electronics, Ltd. (*The Wells Series of Nucleonic Instrument Modules.* Pp. 12. Hayes, Middx.: EMI Electronics, Ltd., 1964). This series of all-transistor modular units can be assembled in any order to provide a wide variety of facilities in the nucleonic instrument field. Individual instruments which can be assembled from the modules include a simple or an automatic counting system, a γ-spectrometer, and a simple or a comprehensive ratemeter for Geiger–Müller and scintillation counter probes. They can be either mains or battery operated. Plug-in printed circuit boards facilitate servicing and a special panel can be supplied if required so that the modules can fit into a standard 19-in. rack. The range of modules at present available consists of a linear amplifier, a single channel pulse-height analyser, a linear rate-meter covering 0–5 kc/s in six linear ranges, a scanning recorder for use with the analyser and rate-meter, a five-decade scaler with a resolution time of 1 μsec, γ-probes and a γ-spectrometer. The range is to be extended.

The Geochemistry of the Rarer Elements

In 1956 the U.S.S.R. Academy of Sciences established a specialist institute for the investigation of the mineralogy and geochemistry of the rare elements (I.M.G.R.E.), from which an extensive flow of publications has since been maintained. Several of its works, including monographs on beryllium, selenium and tellurium, have been translated into English under the ægis of the Geochemical Society. The latest and most important publication of I.M.G.R.E., sponsored jointly by the Academy and by the State Geological Committee, comprises three encyclopædic volumes designed to summarize all aspects of the distribution of certain rarer elements in the lithosphere and hydrosphere (*Geokhimiya, Mineralogiya i Geneticheskie Tipy Mestorozhdenii Redkikh Elementov* (Geochemistry, Mineralogy and Genetic Types of Deposit of the Rare Elements), 1. Edited by K. A. Vlasov. Pp. 688. Moscow: "Nauka", 1964. Price 4*r*. 43*k*.). The first volume is concerned in successive chapters with the geochemistry of the elements Li, Rb, Cs, Be, Sr, Sc, Y, TR, Zr, Hf, Nb, Ta, Cd, Ga, In, Tl, Ge, Se, Te and Re (the actinides and the noble metals are outside the Institute's province). A great deal of new material has been incorporated and the work is likely to remain the most important reference text in its field for a good many years. A second volume, to be published in July 1964, will deal in detail with the mineralogy of these elements, describing the 415 relevant mineral species, of which 26 were first recognized in the laboratories of I.M.G.R.E. The third part of the work is concerned with field geology, paragenetic relationships, and classification of deposits, and will appear early in 1965. Altogether about 80 geochemists have been engaged in this large-scale co-operative enterprise, on the first results of which Dr. Vlasov and his colleagues are to be warmly congratulated.

Milk Iron in a Lactating Marsupial

I. Kaldor and Eric Ezekiel, of the Department of Physiology, University of Western Australia, have administered, in the lactating quokka (*Setonix brachyurus*), parenteral iron, as ferrous ammonium sulphate solution, in an attempt to raise the milk iron (*Austral. J. Exp. Biol.*, 42, Part 1; February 1964). Following a single large intraperitoneal dose, a rise in milk iron occurred within two hours. There was, however, no clear relationship between the rise and the amount of iron injected and there was reason to believe that the rise had been associated with unphysiologically high plasma iron concentrations. During continuous intravenous infusion of iron at controlled rates, plasma iron was elevated to maximal levels not exceeding plasma total iron-binding capacity and, under these conditions, no significant alteration in milk iron occurred within four hours. A progressive and statistically significant rise in total plasma iron binding capacity which occurred during intravenous infusion of iron was probably the manifestation of a redistribution of intra- and extra-vascular transferring in response to the need for more rapid removal of iron from the plasma.

Post-doctoral Fellowships in Neoplastic Growth

The Jane Coffin Childs Memorial Fund for Medical Research supports investigations in the fundamental aspects of neoplastic growth, and awards post-doctoral fellowships to candidates of outstanding potential in the same field. Applications for grants-in-aid are reviewed by the Board of Scientific Advisers and the Board of Managers of the Fund three times a year, in the autumn, winter and spring. Final dates for receipt of applications are September 1, November 1 and March 1. Fellowship applications are reviewed at the winter meeting of the Fund, the final date for applications being October 1 of each year. Grants-in-aid and fellowships are not restricted to United States citizens, but fellowship programmes should involve scientific interchange with the United States. Further information can be obtained from the Office of the Assistant Director, Jane Coffin Childs Memorial Fund for Medical Research. 333 Cedar Street, New Haven, Connecticut 06510.

National Amateur Astronomical Convention

The Rank Taylor Hobson and Ratcliffe College Astronomical Societies are holding their second national amateur astronomical convention at Ratcliffe College, Leicester, during September 4–6. Among the lectures which have been arranged are: "Polar Wander and Continental Drift", by Dr. H. C. King, curator of the London Planetarium; "Radio Telescopes and Radio Observation", by Mr. D. Barber, Royal Radar Establishment, Great Malvern; "Cosmology and Space Research", by Dr. R. C. Jennison, Jodrell Bank Experimental Station; "The Astrophysics of Visual Binaries", by Dr. D. Jones, Royal Greenwich Observatory; "Solar Activity", by Dr. J. Reed, acting director of Dunsink Observatory, Dublin; "Current Work at the Royal Observatory, Edinburgh", by Dr. P. Fellgett, Royal Observatory, Edinburgh; and

"Mechanical Design of Satellite Trackers and Radio Telescopes", by Mr. B. R. Tuppin. An exhibition has been arranged, which will include a satellite tracker model, an *Allouette* exhibit from Canada, and a colour film of the *Blue Streak* rocket. Further information can be obtained from the convention secretary, Mr. J. Maxwell, 81 Gresham Street, Belgrave, Leicester.

University News:

Aberdeen

Dr. R. G. Smith and Dr. P. A. Orkin have been appointed to senior lectureships in engineering and natural history, respectively. Mr. J. H. Savage Blaxter has been appointed to a lectureship in natural history (zoology). Dr. D. A. Archer and Mr. B. J. van der Kamp have been appointed to research fellowships in chemistry and forestry, respectively.

Cambridge

THE report of the head of the Department of Engineering, University of Cambridge, Sir John Baker, for the year 1962–63, records a total of 926 students, an increase of 8 on the previous year, although the undergraduate entry decreased by 5 to 272 (Pp. 14. Cambridge: The University, 1964). Research students in residence numbered 111, almost double the number in 1957 and 14 more than in 1961–62, while 12 postgraduate students took the Course of Advanced Study in Engineering. The main development was that the Electrical Optics in Part I of the Tripos was held for the first time. Some notes are included on research in progress in applied thermodynamics and gas dynamics, control engineering, electricity, fluid dynamics and structures, and there is a list of 95 publications.

Liverpool

THE following appointments to lectureships have been announced: D. W. Dickens (psychology); B. Selby (mathematical statistics); J. C. Wilkinson (numerical analysis); C. H. Taylor-Robinson (bacteriology); M. J. T. Peaston (clinical pharmacology); G. Hall (civil engineering); J. A. Rees (electrical engineering); J. W. Cleaver and Dr. R. P. N. Jones (mechanical engineering).

Sussex

DR. F. G. BAILEY, at present reader in Asian anthropology in the University of London, has been appointed professor of anthropology, with effect from October. Prof. J. F. Sutcliffe, at present professor of botany in the University of London, has been appointed professor of plant physiology. Dr. Marie Jahoda, at present head of the Department of Psychology and Social Science at Brunel College of Advanced Technology, has been appointed professor of social psychology. Dr. N. S. Sutherland, at present lecturer in experimental psychology in the University of Oxford, has been appointed professor of experimental psychology. Prof. J. C. West, at present professor of electrical engineering at Queen's University of Belfast, has been appointed professor of engineering and dean of the school of applied sciences. Prof. R. W. Cahn, at present professor of materials technology in University College, Bangor, has been appointed professor of materials science. The last-mentioned five appointments take effect from 1965. Other appointments have been made as follow: *Reader*, Dr. M. F. Lappert (chemistry); Dr. E. A. Barnard (biological sciences). *Senior Lecturer*, Dr. G. Martelli (experimental physics); Dr. H. R. Post (philosophy of science). *Lecturer*, Mr. R. W. Bott, Mr. J. R. Hanson, Dr. J. B. Pedley and Dr. P. Simmonds (chemistry); Dr. P. J. Bushel, Dr. J. A. Laurie, Dr. R. R. Laxton, Dr. W. Parry and Dr. Rutovitz (mathematics); Dr. M. Springford, Dr. J. Venables and Mr. A. J. Walton (experimental physics); Dr. N. Dombey and Dr. D. A. Goodings (theoretical physics); Dr. R. J. Cole (biological sciences).

St. Andrews

THE following appointments have been announced: *St. Salvator's College*, Dr. D. C. Weeks, senior lecturer in botany; *Queen's College*, Dr. J. McManus, lecturer in geology.

Announcements

DR. B. C. HEEZEN, of the Lamont Geological Observatory, Columbia University, has been awarded the third Henry Bryant Bigelow Medal by the Trustees of the Woods Hole Oceanographic Institution "in recognition of his physiographic studies of the deep ocean and of related marine sedimentary and tectonic processes". This medal, accompanied by a cash prize of 2,500 dollars, was established by the Trustees in 1960, "to be awarded to those making significant inquiries into the phenomena of the sea".

A SYMPOSIUM on "Chromatography", organized by the Belgian Society of Pharmaceutical Sciences, will be held in Brussels during September 14–15. Further information can be obtained from the Secretary, Belgian Society of Pharmaceutical Sciences, 11 rue Archimède, Brussels 4.

THE fourth international conference of the International Association for Analogue Computing will be held in Brighton during September 14–18. Further information can be obtained from the B.C.S./A.I.C.A. Honorary Secretariat, Ferranti, Ltd., Kern House, 36 Kingsway, London, W.C.2.

THE second congress of the Czechoslovak Society of Arts and Sciences, entitled "Czechoslovakia, Past and Present", will be held in Columbia University, New York, during September 11–13. Further information can be obtained from Dr. M. Rechcigl, jun., 1703 Mark Lane, Rockville, Maryland.

THE third International Measurement Conference will be held jointly with the sixth International Instruments and Measurements Conference in Stockholm during September 14–19. Further information can be obtained from the Secretary, Society of Instrument Technology, 20 Peel Street, London, W.8.

THE first Matscience summer school in "High Energy Physics", supported by the Council of Scientific and Industrial Research, will be held in Bangalore during August 24–September 14. Further information can be obtained from the Office of the Director, Matscience, Institute of Mathematical Sciences, Madras 20.

THE 1964 World Conference on Radio Meteorology, which will incorporate the eleventh Weather Radar Conference, will be held at Boulder, Colorado, during September 14–18. Further information can be obtained from Mr. J. W. Herbstreit, Central Radio Propagation Laboratory, National Bureau of Standards, Boulder, Colorado.

THE seventh International Embryological Conference will now be held in London, and not Edinburgh, as announced earlier (*Nature*, 202, 650; 1964), during September 6–10, 1965, at Bedford College, Regent's Park, London, N.W.1. Further information can be obtained from Dr. A. S. G. Curtis, Department of Zoology, University College, Gower Street, London, W.C.1.

THE second International Congress of Endocrinology will be held at the Imperial College of Science and Technology, London, during August 17–22. The programme will include symposia and lectures under the following general headings: general and comparative endocrinology; brain–endocrine relationships; reproductive physiology; clinical problems; tumours; steroid hormones; thyroid hormones; protein and polypeptide hormones. Further information can be obtained from Dr. D. A. Pyke, King's College Hospital, Denmark Hill, London, S.E.5.

INHALED RADIOACTIVE PARTICLES AND GASES

THE third Hanford Biology Symposium, held at Richland, Washington, U.S.A., during May 4–6, 1964, was devoted to inhaled radioactive particles and gases. It was organized by a committee of Hanford scientists under the chairmanship of Dr. W. J. Bair. The 200 participants included representatives of nine countries, who were welcomed by Dr. H. A. Kornberg, head of the Hanford Biology Laboratories.

Proceedings were opened by Dr. W. E. Lotz, head of the Division of Biology and Medicine of the U.S. Atomic Energy Commission. Consequent on the test ban treaty a proliferation of effort was in progress, and a glimpse was given of the novel and interesting outlets for atomic expertise which were being attempted.

Foremost among these were the systems for nuclear auxiliary power units; these are heat sources, operated by various nuclides, in the range 40–240 kilocuries, which generate electricity by thermoelectric inversion, using semiconductors. Lights for marine buoys with a life of 10 years produce 10–60 W; a 25-W generator for a navigational satellite was also described.

Nuclear-powered rocket engines carry a finite risk of re-entry after launching which can be faced by designing either for burn-up or by ensuring that the isotope container remains intact. At a height exceeding 100,000 ft. a fuel cone can disintegrate or burn-up into particles smaller than 10μ which dilute sufficiently in the biosphere to offer no risk; a ground contamination of 2,000 mc./mile^2 would not be exceeded.

Dr. T. T. Mercer (Lovelace Foundation, New Mexico) made a comparison of laboratory and field problems in handling aerosols of mixed fission products; there were hazards associated with natural sources of radon, with fuel melting in accidents and with fuel recovery operations.

Generation of laboratory clouds by aqueous sprays presented the possibility of the aerosol behaving anomalously owing to the particles carrying electric charges. These could arise from statistical fluctuations of ion concentration when liquid was fragmented from bulk. Natanson's theory had been verified at low numbers of particles, the mean charge being proportional to the 3/2 power of the diameter and the square root of the number per cm^3. The charge could amount to 100 electrons per particle. At higher concentrations the charge was independent of the number and proportional to the square root of the diameter.

Such charges can seriously distort deposition from laboratory aerosols and a tritium source was used to discharge them. Sampling had been most successfully carried out with the conifuge, which is a true aerosol spectrometer, in contrast with other so-called instruments, because the aerosol intake stream is narrow and confined between guard layers of pure air, which ensures that the site of deposition is sharply determined by Stokes's diameter. Mass parameters are needed for isotope inhalation investigations and their derivation from particle counts involves shape and density complications. The cascade impactor is useful for sampling because it yields mass parameters directly. Small jets, 0·015 cm diameter operating at 1/3 sonic velocity, had been useful for impacting very small particles.

Particles, particularly those containing plutonium which constituted an inhalation hazard when airborne, were discussed by K. Stewart (U.K. Atomic Energy Authority, Aldermaston). One problem was the large amount of extraneous material which accompanied the dangerous aerosol. For example, 4×10^{-5} μc./m^3 of plutonium was equivalent to only 100 particles/m^3 of 1μ diameter; this is only a minute fraction of the total adventitious aerosol in many circumstances.

High-altitude burn-up results in small particles because the entire mass is expanding; near the surface of the Earth there is massive and inhomogeneous entrainment. There are great difficulties in predicting the outcome of a quenched fireball in water.

Oxidation processes result in aerosols by break-away of particles of oxide from the surface; a higher temperature gives coarser particles. Some alloys had an adherent oxide film. In an ignition of plutonium only some 0·1 per cent of the material was likely to be found in the hazardous range of particle size. Whereas uranium aerosols contained large aggregates of spheres, particles of plutonium were usually individual fragments.

Investigations of the particle size distribution of airborne plutonium in work rooms, using filters, were described by B. V. Andersen, of the Hanford Laboratories. Membrane filters with 2μ pore size had been found useful and 5–50 α-tracks per particle were obtained by autoradiography. As a rough rule, doubling the particle size resulted in a ten-fold increase in radioactivity. $^{239}PuO_2$ was found in lognormal distributions with geometrical standard deviation (σ_g) of 1·8–3. 85 per cent of the activity was in the largest 1 per cent of sizes. Plutonium carbide melt operations yielded the finer clouds with a maximum diameter of $1{\cdot}7\mu$, GMD $0{\cdot}2$–$0{\cdot}48\mu$ and g = 1·4–1·8.

R. E. Albert *et al.* (Department of Industrial Medicine, New York University) have developed techniques for making monodisperse spheres of 'Lucite' and of iron oxide using a spinning disk. The sizes are uniform within 10 per cent standard deviation over a range of 1–8μ. The lucite solution which is fed to the disk contains a tagging isotope—either in carrier-free form or chelated with acetyl acetone. The presence of acetyl acetone in the xylene solution was found essential to the production of spheres with unwrinkled surfaces. These particles are not taken up by phagocytes. Good uniformity has also been achieved in the dispersal of sols of colloidal iron oxide. These particles are stable in water and are taken up by phagocytes. Various isotopes have been used for examining the rate of leaching out. In each case the particles require to be collected from the spinning disk generator and redispersed for experimental work.

Montmorillonite clay will absorb a number of radionuclides by ion exchange and can then be dispersed as an aerosol by spraying a suspension. The technique was described by S. Posner (Lovelace Foundation, Albuquerque). He also found that latex spheres would absorb iodine-131 from solution in ethyl alcohol. Data on isotope leach-out were given.

Two papers dealt with radioactive dust and gas from uranium mines. H. Fusamura *et al.* had sampled radon in Japanese mines with an ionization chamber and transistorized vibrating reed electrometer. The concentration ranged from 0·3 to $10{\cdot}0 \times 10^{-7}$ μc./c.c. and increased to 3×10^{-6} μc./c.c. when the mine ventilation was stopped. Daughter products were collected by filtration and the free ion concentration roughly estimated by placing a 2-m long diffusion tube in front of the filter; it was reckoned that free ions accounted for 20 per cent of the RaA. The dust on the filter contained 0·01–0·08 per cent U_3O_8 which corresponds to 1–45×10^{-3} μc./c.c.

Dr. Palmer (Hanford Biology Laboratories) had taken a whole-body counter to two Colorado uranium mines, one of which was disused and one in operation. Sampling was performed with membrane filters for daughter products and activated charcoal for radon. The counter was used very soon after exposure and the entire length of the subject's body could be scanned. Some 20 per cent of activity was found in the head, 10 per cent in the neck and 70 per cent in the chest. The maximum chest concentration was in the right side, 3 in. off centre. It seemed that all the activity inhaled by the subjects while in the mines was still in their bodies when measured by the counter.

Several papers dealt with the elimination of dust from the lungs, including an outline of the processes by S. Engel. The theory of fluid transport, rather than carriage by phagocytes, to the pulmonary lymph nodes was supported by P. Gross, who considered that insoluble particles which deposit in the alveoli are sequestered on the wall in nodules or plaques, although a few penetrate the wall directly. Sequestered particles may be freed in due course, and eliminated via the bronchial epithelium.

Three phases of clearance, at decreasing rates, were identified by L. J. Casarett and P. F. Milly (University of Rochester); these comprised bronchiolar clearance, phagocytosis from alveoli and transport to the lymphatics. The half-time for alveolar clearance ranges from 15 to 50 days and depends on the material and the animal. Much of the material deposited in the alveolar regions is found in macrophages after 2 h. Chemitaxis is a factor, but different substances do not have half-times in line with their solubilities. Protein binding favours phagocytosis. It was suggested, in the discussion on this paper, that the phagocytosis of radioactive particles may be delayed.

In formulating a theory of dust clearance account had to be taken of the long period during which some particles remained in the alveoli; a macrophage development sequence was visualized in which cells of the alveolar epithelium, which may have been penetrated by insoluble particles periodically detach themselves. According to the way in which the cell lies in the alveolar wall, detachment may proceed either into the air space or into the interstitium.

R. G. Thomas (Lovelace Foundation, Albuquerque) described experiments with aerosols of thorium, plutonium, niobium, uranium and polonium which were inhaled by dogs. All the data were grouped along a straight line when the proportion of lung content in the lymph nodes was plotted against time, using logarithmic scales. The proportion of the whole-body content eliminated in the fæces fell off exponentially much more rapidly than urinary excretion; this indicates the change-over from lung elimination as ciliary removal declines.

A biochemical examination of rabbit lung by J. M. Felts (University of California Medical Center) showed that 8–10 per cent of the oxygen uptake was used in lung tissue for the oxidation of long-chain fatty acids bound to serum albumin. Using carbon-14 it was shown that lung, in contrast to liver, converted fatty acids into phospholipids, mainly lecithin. Glucose probably acts as an acceptor intermediate. Lung phospholipids are a key component of the surfactant which stabilizes the alveoli by reducing surface tension to an extremely small value.

B. B. Boecker *et al.* (Lovelace Foundation) described a new whole-body plethysmograph in which a dog could be placed with its nose protruding through a rubber seal into an aerosol chamber. Air moving to and from the plethysmograph box was recorded with a pneumotachygraph inserted between the box and another sealed chamber. This system eliminates difficulties due to drift of pressure. The boxes were made of ⅜-in. 'Plexiglass' which responded to pressure changes in the room when strong winds blew outside.

An inhalation apparatus for small animals breathing $^{14}CO_2$ was described by D. L. Joftes (New England Deaconess Hospital, Boston). The increase in carbon-14 in the atmosphere is important since carbon dioxide may be a direct precursor of DNA. Assuming the animal fixes 0·5 per cent of the carbon dioxide available, a dose of 0·1 rad was calculated in 10 days. The exposure chamber was provided with constant environment and a metered supply of carbon dioxide up to 4 per cent. Estimates of individual testes by autoradiography and liquid scintillation counting were planned.

Experiments on the inhalation of cæsium-137 by rats had been performed at the Lovelace Foundation by Miss R. Lie. Aerosols of the chloride and nitrate in concentrations between 0·05 and 9·0 per cent were used and tissue and excreta samples analysed for 4 months.

C. E. Miller (Argonne National Laboratory) gave an account of the examination of two persons who had accidentally inhaled cæsium-137. Whole-body analysis was performed by the tilting chair technique and the distribution of cæsium-137 and potassium-40 was found in a low background room using a simulated 7-crystal array. No appreciable amount of cæsium-137 was found in the lungs after 9 days from exposure. There was no translocation over 185 days and a biological half-time of about 80 days was indicated. The nuclide was distributed throughout the body.

A case of human exposure to plutonium-239 was discussed by W. S. Snyder (Oak Ridge). On the model of the 'standard man', an elimination half-time of 120 days is assumed for insoluble lung deposits, most of this material being disposed of in the fæces. There is, however, some indication that plutonium-239, and other heavy metals, reach the blood in significant quantities, so that transfer to bone is possible. The bone may thus be the critical organ. Whereas the lung may carry a higher concentration for the first few years of exposure the bone content would eventually predominate and might become the limiting factor in permitting continuous exposure for a working life.

An investigation of the metabolism of radio-mercury by rats during chronic exposure for two months was performed by A. Rothstein and A. Hayes (University of Rochester). The body burden was determined by whole-body counting and fluctuated with the exposure régime. After three weeks, intake and excretion were in balance. On terminating exposure the body burden declined exponentially with a half-time of 15 days. Most mercury was found in the kidneys; there was an appreciable loss of mercury vapour via the lungs and the skin.

The production of test aerosols for lung clearance investigations in rabbits was the subject of a paper by A. Kajland *et al.* (Karolinska Institute, Stockholm). Octadecanol was dispersed by a spray-fed thermal generator with the nucleating substance dissolved in the octadecanol. The coefficient of variation in particle size was 5–10 per cent for diameters of 2μ–10μ and 20 per cent for 1μ–2μ. A spinning disk spray gave a variation coefficient of 10 per cent for spheres of 'Lucite' produced from a 0·2 per cent solution in 5 per cent acetone and 95 per cent acetamide. The use of a mixed solvent is necessary if smooth, unwrinkled spherical particles are to be obtained.

Lung clearance was measured by a profile-scanning method which allowed multiple examinations and re-exposure of a single animal. It had been observed that the phagocytosis of octadecanol was low.

A novel technique for measuring ciliary clearance from the lungs of rats was devised by A. A. Spritzer and J. A. Watson (Graduate School of Public Health, Pittsburgh). All material swallowed is collected through a polyethylene tube placed in the animal's œsophagus; the caudal end of the tube empties into a 100-c.c. bottle fastened to the flank. Rats were kept alive for 7 days and daily collections were made; there was no interference with swallowing. The pulmonary phlegm was flushed out by the water drunk. Following intratracheal injection of $^{133}BaSO_4$ particles it was found that 8 per cent, or about half the total pulmonary clearance, was by the ciliary mechanism.

Experiments on inhalation by man of aerosol particles were described by L. Dautrebande (Brussels) and W. Walkenhorst (Bergbauberufsgenossenschaft, Bochum, Western Germany); few particles were found in exhaled alveolar air, this being claimed to represent 90 per cent deposition. In contrast, C. N. Davies (Medical Research Council and London School of Hygiene and Tropical Medicine) emphasized, by comparing size distributions of lung dust and airborne dusts, that the access of particles to the alveoli of man during normal breathing, was more limited than was commonly supposed. Curves of alveolar deposition, derived by indirect arguments from total deposition experiments, considerably over-estimated alveolar deposition and could not be explained by phagocytosis from the alveoli.

Calculation of the cancer-related dose from the inhalation of radon and daughter products had been carried out by a synthetic approach by B. Altshuler *et al.* (Institute of Industrial Medicine, New York University). The dose was estimated from the surface activity on the bronchial mucosa, not from material lodged within pulmonary tissue. The atmosphere was supposed to contain 100 pc. (picocuries) of radon, 150 unattached daughter atoms and 200 pc. total daughter products per litre. The deposition of ions, nuclei and particles in the different regions of the respiratory tract was calculated on Landahl's model and the mucus transit time worked out for each region; the available α-activity on the surface of the bronchial mucus at all regions could thus be estimated. Allowing for the thickness of the mucus film and of the epithelial cells, an estimate was made of the dose to the basal cells of the bronchial epithelium throughout the regions. The thickness is a critical factor in the calculations. The basal cells of the segmental bronchi were found to receive the greatest dose, which amounted to 30 rads/working year of 2,000 h. In terms of animal experiments this indicates that the atmosphere assumed would deliver a carcinogenic dose in a working life-time.

A somewhat similar calculation was presented by W. Jacobi (Hahn–Meitner Institute of Nuclear Physics, West Berlin). He took 10^4 particles/cm^3 with an average diameter of 70 mμ for RaB and RaC and 100 mμ for ThB and ThC. The mean percentages of unattached atoms are 100 per cent ThA, 25 per cent RaA and 1 per cent RaB. Deposition and mucus transport in the various regions of the respiratory tract were estimated and the mean biological half-time in the lungs was measured as 8 h. He found, like Altshuler, that the dose from inhaled decay products was not negligible and that the basal cells of the lower bronchi received the highest rate. His overall figure was about 30 per cent below that of Altshuler. It is evident that current normal exposure runs near to the limit.

Observations on the contamination of Yugoslav miners of uranium were described by D. Djuric *et al.* (Institute of Occupational Health, Belgrade). Levels of radon up to 16 times the maximum allowable concentration had been recorded in the past, but improvement of the ventilation system had now been effected.

Assessment of polonium-210 in the urine correlated with radon exposure; the exposure to polonium-210 from dust was gauged by determining polonium, radium and uranium in the dust. There is an exposure to polonium-210 from cigarette smoke.

The pulmonary function of uranium miners had been measured by V. E. Archer *et al.* (U.S. Public Health Service, Salt Lake City). The data suggest that working for short periods in high levels of radon and daughter products improves ventilatory function, but long exposures are detrimental above the losses resulting from ageing and from cigarette smoking. The effects of silicious dust and of radiation could not be separated. The action of the latter comprises specific injury to the bronchial epithelium and diffuse injury to lung tissue. It has been suggested that the inhalation of positive ions causes the bronchi to contract while negative ions produce relaxation. A negative charge on dust particles has been claimed to increase phagocytosis.

G. Saccomanno (St. Mary's Hospital, Grand Junction, Colorado) reported an increase in the lung cancer of uranium miners. Most tumours were undifferentiated, in contrast to 71 per cent epidermoid for a non-uranium miner group. 79 per cent of the tumours were of the oat cell type with a preference for the hilar area.

A general review of the biological effects of radiation on the lung was made by M. Kuschner and N. Nelson (New York University). The syndrome of radiation pneumonitis was defined in 1920. Bronchial mucosal changes include the evolution of abnormal epithelial cells which are sloughed off; along with this an interstitial fibrosis develops. The dose response relationship is poor. Effects have been reported at 500 r and there is 20–50 per cent incidence at 2,000–6,000 r. The fibrosis is related to deposits of inhaled activity; alveolar capillary block may follow with a reduction of diffusing surface area.

Cancer is bronchogenic in origin. Long exposure is necessary to induce it and it was first demonstrated experimentally in 1957. 10^3–10^4 rads will induce tumours. 63 μc. of strontium-90 in a capsule will yield a squamous cell carcinoma of the lung when embedded for 3–15 months.

In calculating dose it is necessary to define a target area in an organ, because cancer does not begin in an organ but in a tissue. It is possible to over-interpret early metaplastic response; for example, the implantation of a 5-μc. ruthenium pellet produced denudation of epithelium followed by regeneration one or two cells deep; chemical irritants give a similar epithelial response. If a tumour is to appear it does so explosively after a steady induction period of metaplasia lasting, in rats, some 120 days; this follows the initial hyperplasia which increases for the first month. Work with S. Laskin showed that the tumour yield was proportional to the amount of radioisotope.

Peripheral tumours develop in areas of fibrosis which may play a part, as in scar cancer. Many Colorado miners have silicosis. Questioned on the nature of malignant change, the speaker said he regarded virus and radiation as co-carcinogens, each a tool which manipulated genetic material.

H. Cember (University of Cincinnati) had induced lung tumours in rats with the chloride and fluoride of cerium-144. Intratracheal doses of 0·5–50 μc. were injected. The mean radiation dose absorbed during survival time was calculated from lung clearance data and when plotted against the cumulative tumour frequency, extrapolated to zero at a value of 250 rad. This is interpreted as the threshold dose for lung tumour induction in rats by radioactive particles in the lungs.

The inhalation of $^{144}\mathrm{CeO}_2$ by dogs was the subject of a paper by B. O. Stuart, A. W. Casey and W. J. Bair (G. E. Hanford Laboratories). Aerosols of various particle sizes between 0·09μ and 1·40μ were administered and the amount deposited ranged from 50 to 2,200 μc. The effective half-life was similar to the radioactive one, 285 days, and the biological half-time was 1·5–5 years. Up to 900 μc. failed to produce significant change in blood gas or serum enzyme, but heavy doses up to 130 kilorads produced severe damage in lungs, mediastinal lymph nodes and liver. 22 per cent of the body burden at death was in the lungs, 44 per cent in the liver and 27 per cent in bone.

From the same laboratories a paper by J. W. Park, W. J. Clarke and W. J. Bair dealt with the chronic effects of inhaled $^{239}\mathrm{PuO}_2$ in dogs. The aerosol was generated by calcining in air at 300° C. The radiation dose to the lungs was 9–23 kilorads; the clinical symptoms were cardiopulmonary defect and lymphopenia. Bronchial and interstitial tumours were found, locally invasive and of multiple origin. No metastases were seen. For the period of exposure, up to 48 months, the lung was the critical organ causing death.

An original technique for the safe radiological visualization of the human lung was due to G. V. Taplin *et al.* (University of California).

Serum radioalbumin in a 1 per cent solution is readily aggregated by adjustment of *p*H and heating at 79° for 20 min. 10–20 mμ particles act like bacteria and are removed by the liver on first passage. By lowering the *p*H macro aggregates of 5–50μ are formed. These are too large to pass through the capillaries of the lung, where they are temporarily trapped for 1–2 h. The lung can be scanned photographically during this period, and on the resulting picture it is possible to detect pulmonary emboli, lung infarcts, pneumonia, atelectasis, certain tumours and cysts causing local ischæmia.

Work at the U.S. Public Health Service (Taft Laboratories, Cincinnati) on the intake of radiostrontium by infants was presented by B. Kahn *et al.* Levels in air, water and prepackaged baby foods were measured and the ingestion calculated. Retention was deduced by subtracting the activity in the excreta; strontium-89 and -90 are present in air in soluble forms.

The last papers read dealt with the removal of inhaled radioactive materials. I. Schmidtke (University Clinic, Freiburg-im-Breisgau) treated guinea pigs with diethylene triamine penta acetic acid after exposure to $^{91}YCl_3$ aerosol. A 95 per cent diminution of retention was found, in comparison with untreated animals, after 8 days. The action was mainly on the kidneys, and most of the activity was recovered from the urine. E. G. Tombropolous (Hanford Laboratories) considered that chelating agents were the most effective means, when applicable, of removing radioactive particles from the lungs. Drugs which decrease mucus secretion or increase phagocytosis are also worth testing. F. Gensicke and H. W. Nitschke (German Academy of Sciences, Berlin-Buch, G.D.R.) reported that sodium hexametaphosphate had a scavenging effect on inhaled yttrium-91 in mice.

Papers read in title dealt with a spinning disk atomizer, a routine technique for estimating plutonium in large biological specimens, fall-out from burnt-up uranium and plutonium, Zr-^{95}Nb in human lungs from medium life fission products in the atmosphere, atmospheric analysis for total β-activity and the monitoring of human subjects who had accidentally inhaled fission products.

The papers will be published in full in the December 1964 issue of *Health Physics*. C. N. DAVIES

BIOSYNTHETIC PATHWAYS IN HIGHER PLANTS

THE biosynthetic pathways leading to all the major groups of compounds present in higher plant tissues were discussed at the seventh annual general meeting of the Plant Phenolics Group which was held at Bodington Hall, University of Leeds, during April 13–15. The wide range of topics covered by the symposium coincided with a decision by members to change the name of the Group to the Phytochemical Group with the view of promoting the advancement of the chemistry, biochemistry and related sciences of all plant products.

The opening address was given by Prof. N. A. Burges (University of Liverpool), who discussed the biological aspects of biochemical reactions and the possible differences between reactions *in vivo* and *in vitro*. This is an important consideration which is still sometimes overlooked by chemists. Biochemical reactions *in vivo* are commonly studied by feeding in potential precursors labelled with 'heavy' or radioactive isotopes. Dr. T. Swain (Low Temperature Research Station, Cambridge) gave a critical account of these methods. In particular he noted that feeding experiments often led to an understanding of the starting and end points of a pathway but gave little information regarding the individual steps and the control mechanisms. He emphasized the need for investigating the enzymes which catalyse each step, and he brought to the attention of the meeting other conditions, such as environmental and genetical factors, which could affect biosynthesis.

The first paper on a particular group of plant constituents was presented by Prof. T. W. Goodwin (University of Aberystwyth), who gave an account of the formation of terpenoids, compounds which appear to play a key part in chloroplast development. When etiolated seedlings are illuminated there is a massive synthesis of terpenoids as the functional chloroplasts are produced. During the greening period, carbon dioxide but not mevalonate is incorporated into the chloroplast terpenoids, but the reverse is true for the related sterols which are also present. It is believed that the biosynthesis of terpenoids in developing seedlings is regulated by enzyme segregation and specific membrane permeability. A second paper concerning the detailed steps involved in the elaboration of carotenoids, starting from acetate, was also presented by Prof. Goodwin.

An account of the amino-acids found in plants was given by Dr. L. Fowden (University College, London). In his lecture he concentrated on the large number of non-proteinogenic derivatives of which at least two groups are recognized. First, those which are intermediates in the formation of the twenty protein amino-acids and also those which arise by the non-specific action of enzymes normally associated with the metabolism of the proteinogenic compounds. The role of most of them is unknown.

Studies with micro-organisms have provided evidence that DNA controls the synthesis of proteins. This evidence was reviewed together with the mechanism of amino-acid polymerization by Dr. D. Boulter (University of Liverpool). He also described the similar findings made with higher plants and commented on the work being carried out at the University of Liverpool on protein synthesis in developing seeds.

The vast field of carbohydrate biochemistry was also reviewed (Dr. J. S. D. Bacon, Macaulay Institute, Aberdeen) mainly with reference to simple sugar phosphates and the more complex nucleotides derived from them. The synthesis of insoluble polymeric carbohydrates still remains something of a mystery. For example, although cellulose is the most abundant plant polysaccharide, we know very little about the formation of this material. Recent investigations by Hassid *et al.*[1] at Berkeley have implicated guanosine diphosphate glucose, and Prof. R. D. Preston (University of Leeds) was able to tell the Group of other interesting observations, of a biophysical nature, which help in the general understanding of this problem. He discussed the arrangement of cellulose microfibrils in the cell-walls of seaweeds and showed electron micrographs of spherical granules which are apparently involved in the synthesis and orientation of the polymer strands.

An equally complex problem, which was summarized by Dr. F. A. Isherwood (Low Temperature Research Station, Cambridge), is the structure and biogenesis of lignin. Progress in this field has slowed down considerably during the past few years and the molecule still refuses to give up all its secrets. There is little doubt, however, that the aromatic rings in this polyphenol are derived from shikimic acid and it is probable that the

$C_6 : C_3$ units, of which it is composed, are condensed together in a random fashion. The development of methods for determining the sequence of these units in the polymer is, therefore, awaited with great interest. The shikimic acid pathway is also utilized by plants for the formation of flavonoids. Prof. H. Grisebach (University of Freiburg) described recent theories regarding the synthesis of these pigments. These involve the condensation of cinnamic acids with malonyl-CoA, but so far the formation of the necessary activated cinnamic acids has not been demonstrated using plant enzymes.

The early stages of hæm and chlorophyll biosynthesis follow a common pathway and this has been deduced mainly by investigations with preparations from animal tissues and photosynthetic bacteria. Dr. J. Lascelles (University of Oxford) outlined this chain of reactions and gave an account of the interesting investigations which are in progress, using *Chlorella* mutants and photosynthetic bacteria, on the final stages in chlorophyll synthesis.

The final paper in the symposium, by Prof. S. L. Ranson (University of Newcastle), was concerned with the formation of aliphatic carboxylic acids by plants. Some of these, such as malate, citrate and oxalate, commonly accumulate to a relatively high concentration in the cell. Others, such as fumarate and aconitate, accumulate infrequently. Why some cells accumulate one acid and others a different acid is a problem which remains to be settled.

The Group is indebted to the University of Leeds for the facilities which were placed at its disposal at Bodington Hall. Profs. F. C. Happold, I. Manton and R. D. Preston, all from the University, kindly acted as chairmen during three of the symposium sessions. J. B. PRIDHAM

UNUSUAL FORMS AND ASPECTS OF CANCER IN MAN

EITHER too much or too little tends to be made of the rarities in medicine: purely chance phenomena are described *in extenso*, whereas sight is lost of significant observations in the flood of scientific literature. The conference held by the New York Academy of Sciences on "Unusual Forms and Aspects of Cancer in Man", in October 1963 (ref. 1), was an attempt to assess the importance of certain cancer rarities by grouping them together and discussing them in open forum. Many of the data and views presented at the conference had previously been put forward elsewhere. However, earlier communications were scattered through a variety of journals and several were not widely known. The publication of the proceedings of the conference therefore constitutes a valuable addition to the medical literature.

The comparative value of different types of cancer treatment can be assessed relatively simply, but it is less easy to assess the value of treatment *per se* during an era in which almost every case receives some form of therapy. From his survey of 250 female cases of untreated breast cancer included in the 1805–1933 records of the Middlesex Hospital Charity, Bloom[2] comes to essentially the same conclusions as Doland[3], Greenwood[4] and Nathanson and Welch[5]. He records a mean survival period of 3¼ years from the onset of symptoms, with almost 20 per cent of patients surviving for 5 years and 3 per cent for 10 years. Bloom is satisfied that all generally accepted methods of treatment both prolong life and reduce suffering from the effects of the disease. On the other hand, it appears that no measurable improvement in the results of treatment of breast cancer has occurred during the past few decades[6]. The possible value of radiography in the detection of early breast cancer has been under investigation for more than thirty years, but, mainly because of failures in techniques, it has not found general favour. It is now clear that, in the hands of the expert, mammography sometimes results in the detection of breast cancer before a positive diagnosis could be made clinically by inspection and palpation[6,7]. Nevertheless, in the opinion of Egan[6] it is too early to opine whether biannual mammography should be used to screen the female population for early breast cancer.

In an age of nuclear weapons, the carcinogenic effect of ionizing radiation is a political issue. It has therefore achieved more prominence than is justified by the facts. Investigations on the survivors of Hiroshima and Nagasaki[8] revealed the expected excesses of myeloid leukæmia[9] and thyroid cancer[10]. In addition, an excess of anæmia due to myelofibrosis has been observed. Many of the thyroid cancers were microscopic and did not contribute to the death of the victim. Moreover, the incidence of small foci of thyroid cancer has not been adequately investigated in comparable unirradiated populations. This raises another problem. One is apt to assume that there is little scope these days for changes in standards of diagnosis. In fact, attempts at earlier diagnosis[6,7], increasing autopsy rates, the classification of microscopic lesions as cancer[8,11,12], and a gathering interest in aged patients[13] are steadily altering the background against which other more closely investigated events are studied.

It is generally held that the majority of lung cancers arise in the large bronchi within a few inches of the bifurcation of the trachea. It is within the same areas that the particulate matter present in inhaled tobacco smoke and polluted air tends to be deposited[14]. Rigler presents a survey of patients in whom routine chest roentgenograms were taken at intervals prior to the diagnosis of lung cancer. The first radiological signs were usually present almost a year before the onset of significant symptoms. In some cases the interval between the first sign and the making of a definitive diagnosis was as long as 5–10 years. The finding that the majority of tumours arose in the lung periphery and were not symptomatic until they had spread centrally is surprising, since it suggests that the deposition of particulate matter is not closely related to cancer induction. One wonders how often centrally arising tumours would have been detected radiologically in their early stages, and to what extent Rigler's conclusions are influenced by the fact that they are based on selected material.

Successful treatment of cancer discovered during pregnancy may involve the loss of the fœtus. Most would regard this loss as an unfortunate necessity, but whether the discovery of cancer *per se* provides grounds for the deliberate termination of pregnancy is another matter. Rarely, cancer cells cross the placental barrier and grow metastatically in the fœtus[15,16]. The demonstration of so-called vertical transmission of murine leukæmia viruses[17,18] prompts the search for examples of similar transmission of tumour viruses in man. However, as yet no human tumour viruses have been positively identified. A few forms of cancer have an undoubted familial tendency. It is exceptionally rare for one of these types of cancer to be diagnosed for the first time during pregnancy. Cancer during childhood is rare, and the occurrence of two cases in one family suggests a transmitted genetic or viral factor. Dargeon[15] records six examples of malignant disease arising in two children of the same family: in no case was it possible to say whether these arose as the result of coincidence, transmission of a genetic aberration, or transmission of a tumour virus, and in no case was malignant disease recorded in the mother during or before either of the pregnancies. The remaining consideration is whether the continuance of the pregnant state adversely affects the progress of the cancer. This is a complicated question without any clear answer. Most would agree that it is necessary to judge each case separately on its merits.

If cancerous foci of microscopic dimensions are taken into consideration, the incidence of multiple primary malignant neoplasms is relatively high. Moertel[19] writes, "The traditional concept of carcinoma as a single neoplasm intruding in an otherwise normal tissue is not always tenable. In a significant number of cases the initial neoplasm is only the first and most obvious manifestation of a carcinogenic process that may involve a large portion, or all, of a given tissue". Mersheimar, Ringel and Eisenberg's[20] results suggest that second cancers arise in the same tissue or system more frequently than would be expected by chance where the first cancer was in the breast, skin, colon, rectum or genito-urinary tract. According to Moertel[19], these findings should be taken into account in deciding the best treatment for cancers of these sites.

A series of contributions on the occurrence and treatment of certain uncommon or rare neoplasms are valuable for reference purposes. Of more general interest are papers on the relation between immune mechanisms and cancer and on the spontaneous regression of cancer. According to Grace[21], the immunological impairment not infrequently observed in cancer patients[22,23] is often related to disease directly affecting the lymphatic system. On the other hand, there are several examples of patients reacting immunologically to components or products of their own tumours; and the failure of advanced cancer patients to accept autografts of their own tumours is a puzzling phenomenon which needs further investigation. Everson's[24] survey of examples of the spontaneous regression of cancer is superb and it would be fitting to conclude this article with his assessment of the significance of this phenomenon: "(1) The existence of spontaneous regression of cancer, in at least some cases, supports the concept of biologic control of cancer and reinforces the hope that a more satisfactory method of treating cancer than surgery and/or radiation, may be found in future years.

"(2) The occurrence of spontaneous regression of cancer demonstrates the need for caution in the assessment of the value of chemotherapeutic and unorthodox therapeutic measures in isolated 'cures' of cancer.

"(3) The possibility of spontaneous regression of cancer must be considered in the evaluation of the prognosis of certain cancers. The remote possibility of spontaneous regression of cancer may be of some psychotherapeutic value in the patient with cancer which is not amenable to surgical and/or radiation treatment." F. J. C. Roe

BRITISH TECHNICAL CO-OPERATION OVERSEAS

In replying to a series of questions in the House of Commons on June 25, the Secretary for Technical Co-operation, Mr. R. Carr, said that he was charged to give the sort of help to the developing countries which they themselves said they most needed. British Embassies and High Commissions kept under review the progress and results of his Department's work, and specialist advisers and other staff from his Department made frequent tours overseas. The £175 million spent on overseas aid this year was a record figure and illustrated the rapid rate of expenditure over recent years. Consultation with the Agency for International Development in the United States was close and continuous. The 2,900 recruited under the auspices of the British Government in 1963 for service in the developing countries included a very small number not of British nationality; the 1962 figure was 2,300. Questioned as to alleged difficulties experienced by professional people in finding suitable employment on return to Britain from service overseas, Mr. Carr said that the Overseas Services Resettlement Bureau has been set up specially to assist members of the Overseas Civil Service retiring prematurely, and was doing so with outstanding success. His Department did all it could to encourage employers to release staff on terms which provide for their re-absorption and also to encourage general recognition that overseas service is of positive value in a professional career. He would welcome assistance in making the arrangements better known.

On Latin America, he said that more than £500,000 had been allocated from his Department's funds in this financial year compared with £90,000 in 1963, and this represented about 2 per cent of Britain's total bilateral technical assistance expenditure and about 20 per cent of that allocated to foreign countries. Much of the £400,000 allocated by the British Council to Latin America was also for technical assistance, and he hoped there would be 70 experts in Latin America by the end of the year. Britain could probably help most in agriculture and natural resources work and in technical education.

During the past 12 months, Mr. Carr said he had had requests for training in the United Kingdom of 20 Indians for maintaining and operating new plant to be installed at the Durgapur Steel Works; for 4 engineering experts to assist the chief construction engineer; and for continuing the services of the British general manager until September 1965. More than 400 Indian steel workers had been trained in Britain, and Britain had also supplied substantial managerial and technical staff to the Durgapur Steel Works. Mr. Carr estimated that Britain's expenditure on technical assistance in Malaysia, excluding the Overseas Aid Service, would be about 50 per cent higher in 1964–65 than in 1962–63.

On locust control, he said that the work of the Anti-Locust Research Centre had become the basis for the international strategy of locust control. Two of the major types of plague locust had now been under control for more than 10 years and a third was at its lowest ebb for 24 years. The cost of killing a swarm of locusts had been reduced by 98 per cent compared with 20 years ago. The Centre had recently moved into new premises, which gave it greater scope. On the whole, research, including much field work, was done in Britain. Mr. Carr also referred to a startling and satisfactory increase in recruitment of teachers, which had risen by 300 per cent since his Department was established, compared with an average increase in recruitment of 80 per cent. Doctors still constituted a difficult field. Expenditure on bilateral assistance to foreign countries had risen by 170 per cent and was now 10 per cent of the total.

On research institutions in East Africa and the Caribbean, Mr. Carr said that the 27 such institutions in these regions employed about 250 senior and 350 supporting scientific staff and were doing most valuable work in medicine, agriculture and the development of natural resources. He had no specific proposals for increased grants before him at the moment, and his Department's research expenditure was now on a triennial basis. He estimated that his Department's expenditure on technical assistance to Pakistan was about £650,000 in 1962–63 and it would be about 20–30 per cent higher in 1964. He was somewhat disappointed at the initial response to the scheme of Commonwealth awards to university teachers. His Department employed or supported financially more than 1,200 research staff in research on problems affecting developing countries at a cost of about £2 million a year: just more than a quarter were in home-based units. Under the Low-priced Books Scheme, the university text-books series was available to 32 African countries and included technical and other text-books suitable for use in technical colleges. Preliminary investigations were being made of problems involved in extending the scheme to Latin America, but no decision had been taken.

In a written answer on June 25, Mr. Carr gave the number of overseas students in full-time education in Britain in 1950 as about 12,500, compared with 64,320 in 1963, of whom 50,100 were from the developing countries. In January 1963, 2,600 teachers were serving in developing countries who had been appointed under the auspices of the British Government; just more than 1,300 were appointed in 1963 and more than 400 were sent out by other bodies, in addition to an unknown number recruited direct.

Also in a written answer on June 25, Mr. Carr gave the distribution of the 915 research workers overseas supplied by his Department, 643 of whom were in Africa, 142 in the West Indies and 108 in the Far East and the Pacific. Of these at December 31, 1963, 343 were senior staff, 36 being directly employed, 18 supported 100 per cent, 251 between 50 and 100 per cent, and 38 less than 50 per cent supported. For the supporting staff, the figures were: 100 per cent, 10; 50–100 per cent, 485; and less than 50 per cent, 77. Twenty of those directly employed were in agriculture, including forestry; 2 in veterinary science; 5 in medicine; and 9 miscellaneous. Twenty-seven of those receiving 100 per cent support were in medicine. Of those receiving 50–100 per cent support, 383 were in agriculture, 41 in fisheries, 53 in pest control, 118 veterinary and trypanosomiasis, 99 medical, and 12 social and economic sciences. Of those receiving less than 50 per cent support, 30 were in agriculture, 49 in pest control, 4 veterinary science, 18 medical, and 8 social and economic sciences.

DEVELOPMENT AND SUPPORT OF SYSTEMATICS IN BRITAIN

At present many universities are re-considering the teaching of biology and proposing a unified syllabus. A recent committee of the Royal Society has made certain recommendations on the place that taxonomy should take in the development of biology[1]. The Systematics Association (c/o British Museum (Natural History), Cromwell Road, London, S.W.7) has appointed a small committee to consider the part the universities should play in this development. Members of the committee are: Prof. P. C. Sylvester-Bradley, Department of Geology, University of Leicester; Dr. V. H. Heywood, Hartley Botanical Laboratories, University of Liverpool; Dr. P. H. A. Sneath, National Institute for Medical Research, London, N.W.7. The committee felt that in any consideration of university policy on systematics it is important to distinguish between the broader field of systematics, which is concerned with the scientific study of the diversity and differentiation of organisms and the relationships which exist between them, and taxonomy, which is that part of systematics which deals with the study of classification, including its bases, principles, procedures and rules. Their respective roles in general biological courses and in the specialized training of taxonomists are different. The following aspects, although they interact with each other, should be considered separately: (1) the teaching of systematics at the undergraduate level; (2) the training of taxonomists; (3) the promotion of research in systematics.

The role that systematics should occupy in undergraduate courses in biology has been hotly debated in recent years. Some university biology departments hold that everything that is not molecular biology or biochemical physiology is 'systematics'. Thus such diverse fields as anatomy, morphology, palynology, ecology, cryptogamic botany, palæontology, populations genetics, etc., have been added to the responsibilities of the systematist. Partly as a consequence of these views, and partly as a result of the rapid expansion of the frontiers of biology into chemistry and physics, the expansion of systematics, not only to serve biology by the production and interpretation of classifications, but also to assume responsibility for the furtherance of several of its basic fields, has led to a situation that needs to be pondered by all biologists. Some experimental biologists feel that systematics has an insufficiently rigorous scientific basis, and have thus accorded to the subject a limited portion of the timetable. All too often the resources and staff allocated are quite inadequate for systematics to be carried out effectively. As a consequence many of the basic biological disciplines on which we depend for the consolidation of our factual information are in a state of neglect. The result of these attitudes is that it is becoming difficult to obtain suitably qualified staff in many fields, and this in turn leads to failure to apply modern techniques to these fields.

The point of view that these subjects have been bypassed by modern developments in biology is untenable. Although anatomical investigations may lack the glamour of molecular biology, it is research in systematics which contributes to the advance in our knowledge of whole organisms and on which we ultimately rely for a full comprehension of the significance of biological science.

The importance of systematics in biological courses was considered at a meeting of the Systematics Association in Birmingham, on the "Place of Taxonomy in the Teaching of Biology"[2]. There the role of systematics as a focus for the integration of knowledge on biological diversity was stressed, and this, it must be pointed out, is quite independent of the special interests of students. In other words, it is important for all biological students, not just for potential taxonomists.

Little attempt has been made in Britain, largely due to the departmental system, to teach systematics as a unified subject. Thus it is possible for the same topics (classification, phylogeny, species concepts, evolution, etc.) to be taught separately and in widely diverse (sometimes even conflicting) ways in different departments within the same biological school. Wherever possible, taxonomy should be taught as a unified subject and not compartmentalized between botany, palæontology, zoology, etc.

The teaching of taxonomy in Great Britain could often be greatly improved. In many universities it is not taught at all in a recognizable form. Undergraduate teaching in taxonomy should enable the student to negotiate with reasonable success almost any group of organisms without being a specialist in them, and with a minimum of help from specialists. To achieve this it is necessary to instil the basic principles of taxonomy which are applicable, with some modification, to all groups of organisms. At the same time, teaching should not be restricted to narrowly taxonomic subjects, but should include the wider aspects of systematics and be integrated with evolutionary, cytological, genetical and physiological work. On the other hand, systematics without taxonomy will lead to an equally unbalanced point of view.

The specialized training of students in taxonomy must of necessity follow the undergraduate course. The kind and duration of the training will depend to a large extent on the future occupation which is envisaged for the candidates. One approach is to establish one-year M.Sc. or diploma courses in taxonomy, like those recently initiated at Edinburgh and Liverpool. These are directed at providing adequate preparation in taxonomic methods and procedures for those who are unable to spend 2–3 years on a Ph.D. course, or who do not require such extensive training (it should be remembered that a short taxonomic training may be required for people working in related fields). For the successful running of such 1-year training courses it will be necessary to establish postgraduate schools of taxonomy, each staffed by several taxonomists. Two or three universities should set up such schools as part of their forthcoming expansion plans. Wherever possible they should be based on existing nuclei in universities where the existing staff and facilities could be quickly increased. There is also much to be said for such a school to be formed at one of the new universities. The appointment of additional taxonomists scattered over the country is not a satisfactory alternative to the establishment of a few postgraduate schools of taxonomy, since lone taxonomists can no more be expected to make a satisfactory contribution to teaching and research in a large biological school than can any other lone scientists.

After a training course for one year in taxonomic methods, as suggested here, the best experience for a future taxonomist is a period of creative research leading to a Ph.D degree. This stage will require special herbarium, museum or library facilities. It is for this reason that the number of schools of taxonomy should be limited. Adequate provision for the financing of fieldwork, both at home and abroad, should be made, and this will be assisted by the proposal to set up "Wallace" studentships made in the Royal Society Report[1]. It is also essential that financial provision be made for travel to consult material in other institutions, in this country and abroad.

Research in taxonomy and systematics is closely linked with teaching and training in these fields. Thriving research schools cost money, and it should be the aim of the schools of taxonomy which are recommended here to provide facilities which are comparable with the best found in the United States and on the Continent. In some of the fields of systematics which are listed below as appropriate for further development, little satisfactory progress can be made if the basic resources are not available. There is a need for intimate practical knowledge of traditional approaches if radical new developments are to be expected. A large number of such developments of interest both to systematics and taxonomy are being initiated even with the limited support that is at present available. But there are many aspects of taxonomy which have remained essentially unchanged for decades or even centuries, and up-to-date methods are neglected. This is in part a consequence of the concentration of Britain's taxonomic resources in the national museums which are largely obliged—by their nature and finance—to restrict the amount of pure research they can carry out without prejudice to their heavy practical obligations. Their divorce from the universities and academic research institutions further aggravates this situation. It is urgent that, in addition to the build-up of basic resources and facilities in a few selected universities, substantial support should be given to setting up research units in such fields as comparative biochemistry, comparative physiology and ethology, comparative serology, data-processing methods and machines, developmental physiology, environmental control, epigenetics, population cytology, DNA comparison, numerical taxonomy, palæobiochemistry, protein-sequence taxonomy and theoretical taxonomy.

Systematics occupies to-day a dual role in biology. Systematists have the function of evaluating, interpreting and co-ordinating the greatly increased flow of data from many fields so as to serve biology as helpfully as possible. They are also having to assume, increasingly, responsibility for developing many of those aspects of biology that are discarded by its advancing spearheads. If other biologists wish systematists to occupy these roles effectively, they must be prepared to accept that adequate support be made available to them for teaching and research.

B.B.C. ENGINEERING MONOGRAPHS

SEVERAL times a year the Engineering Division of the British Broadcasting Corporation publishes a monograph either describing some novel technical equipment used in the development and operation of the Corporation's sound and television services, or making an appraisal of some aspect of its engineering activities. For example, *Monograph* No. 46 was published in February 1963, under the title *The Application of Transistors to Sound Broadcasting*, by S. D. Berry[*]. This describes the circuit arrangements and mechanical construction of a number of transistor audio-frequency amplifiers and associated apparatus designed for general use in the sound broadcasting services of the B.B.C.

Of a somewhat different type is *Monograph* No. 48 (June 1963) entitled *The Development of B.B.C. Internal Telecommunications*, by J. M. Chorley and J. S. Norwell[†]. In order to support the sound and television broadcasting services a comprehensive network of telecommunications is essential. While the British Post Office provides many of the required facilities over its country-wide network, the Corporation is concerned with special circuits and, particularly, with their termination at various centres throughout the United Kingdom. This *Monograph* traces the development of such B.B.C. telecommunications and describes some of the equipment used. It does not, however, deal with the distribution of television and sound programmes.

---

[*] British Broadcasting Corporation. *BBC Engineering Monograph*, No. 46: *The Application of Transistors to Sound Broadcasting*. By S. D. Berry. Pp. 20. (London: British Broadcasting Corporation, 1963.) 5s.

[†] British Broadcasting Corporation. *BBC Engineering Monograph*, No. 48: *The Development of BBC Internal Telecommunications*. By J. M. Chorley and J. S. Norwell. Pp. 23. (London: British Broadcasting Corporation, 1963.) 5s.

The most recent of the published *Monographs* (No. 52: March 1964) is entitled *Stereophony: The Effect of Cross-Talk Between Left and Right Channels*, by H. D. Harwood and D. E. L. Shorter‡. As the short list of references appended to this publication shows, the B.B.C. has been exploring the practical possibilities of stereophonic broadcasting for several years. One of the technical defects which may appear in a stereophonic sound system is the unintentional transfer of a portion of the signal in one channel to the other channel, a phenomenon known as 'cross-talk' in telephone engineering. This results in a displacement or blurring of the reproduced sound images. The experiments described have covered the investigation of certain occurrences of cross-talk increasing at high or low frequencies, as well as cross-talk being independent of frequency. It was concluded that the minimum perceptible degree of cross-talk is influenced to some extent by the position of the observer in the listening room, but is largely independent of the acoustics of the room and of the bandwidth of the system.

Other *Monographs* published recently deal with such differing subjects as the measurement of the non-linear distortion generated by a loud-speaker system, and the methods of testing and measuring the properties of lenses used in the photoelectric components of television cameras. All these publications serve to demonstrate the extent to which the operation of the British Broadcasting Corporation's services are well supported by the comprehensive work of the Research, Designs and Lines Departments of the Corporation's Engineering Division.

ISOLATION OF SEROLOGICALLY ACTIVE FUCOSE-CONTAINING OLIGOSACCHARIDES FROM HUMAN BLOOD-GROUP H SUBSTANCE

By Mrs. VAIJAYANTI P. REGE, Dr. T. J. PAINTER, Dr. WINIFRED M. WATKINS
and Prof. W. T. J. MORGAN, C.B.E., F.R.S.
Lister Institute of Preventive Medicine, London, S.W.1

THE results of hæmagglutination inhibition experiments demonstrated more than ten years ago that L-fucose, or more exactly an *O*-α-L-fucopyranosyl structure, is an important part of the serologically specific grouping in the H-specific blood-group substance[1]. Since that time other evidence, involving the inhibition by L-fucose of the enzymatic decomposition of H substance[2] and the demonstration that L-fucose is the sugar most readily liberated from H substance by the action of specific H-decomposing enzymes from *Trichomonas foetus*[3] and from *Bacillus fulminans*[4], has supported these early conclusions. More recently, results of a further serological analysis[5] with the eel serum anti-H reagent suggested that the L-fucose concerned in H specificity may be joined to the next sugar by an α-(1→2) linkage. Thus, 2-*O*-α-L-fucopyranosyl-L-fucose and 2-*O*-α-L-fucopyranosyl-D-galactose are more powerful inhibitors than either 3-*O*-α-L-fucopyranosyl-L-fucose or 4-*O*-α-L-fucopyranosyl-L-fucose.

Difficulties in drawing clear-cut inferences from these results arise from the fact that methyl-α-L-fucopyranoside inhibits the eel reagent as strongly as the disaccharides containing the α-(1→2)-linkages and that other oligosaccharides, such as lacto-N-fucopentaose I (ref. 6), are poor inhibitors of hæmagglutination although they contain α-L-fucopyranosyl-(1→2)-galactose units as terminal non-reducing end-groups. The anti-H reagent extracted from *Lotus tetragonolobus* seeds shows similar anomalies[5], and it was pointed out that the failure to obtain greater inhibition with α-L-fucosyl-(1→2) compounds than with the simple methyl α-L-fucoside might be due to the limitation imposed by the heterologous nature of the eel and plant seed anti-H agglutinins, the receptor sites of which may be largely saturated by a simple α-L-fucopyranosyl grouping. Nevertheless, further support for the belief that L-fucose is linked α-(1→2) in the H determinant structure was gained from experiments with partially purified enzymes from *T. foetus*[7]; preparations which destroy the serological activity of H substance split fucose from oligosaccharides in which the sugar is joined by α-(1→2) linkage to galactose but not from an oligosaccharide in which L-fucose is joined by a (1→4) linkage to *N*-acetyl-D-glucosamine.

That more than one terminal non-reducing sugar residue may be important for H specificity was indicated by inhibition experiments with anti-H reagents from seeds of the plants *Cytisus sessilifolius* and *Laburnum alpinum* These reagents are strongly inhibited by human H substances but are not inhibited by L-fucose[8]. The disaccharide 4-*O*-(*N*-acetyl-β-D-glucosaminopyranosyl)-*N*-acetyl-D-glucosamine (*N*,*N'*-diacetyl-chitobiose), however, inhibits both *Cytisus* and *Laburnum* reagents[8], indicating that an *N*-acetyl-β-D-glucosaminopyranosyl structure may be a serological determinant unit in H-substance in addition to an α-L-fucopyranosyl residue.

Valuable as the results of inhibition and enzymatic experiments are as indirect pointers to the structures of the serologically active groupings in the blood-group macromolecules, the final proof of structure must rest on the chemical characterization of active fragments isolated from the substances themselves. Examination of the four di- and the three tri-saccharides obtained from the partial acid hydrolysis products of a human blood-group H specific substance[8,9] revealed two serologically active fragments, the disaccharide 3-*O*-(*N*-acetyl-β-D-glucosaminopyranosyl)-D-galactose, and the trisaccharide *O*-(*N*-acetyl-β-D-glucosaminopyranosyl)-(1→3)-*O*-β-D-galactopyranosyl-(1→3)-*N*-acetyl-D-galactosamine. These compounds, however, inhibited only the *Cytisus* anti-H reagent and failed to inhibit human, rabbit or eel anti-H agglutinins. This is not surprising, as none of the oligosaccharides described contained L-fucose owing to the rapid liberation of this sugar under the conditions of hydrolysis used. An investigation of the isolated fragments indicated the presence of two main types of carbohydrate chain in H substance for which the following partial structures were proposed[9]:

(1) β-Gal-(1→3)-β-GNAc-(1→3)-β-Gal-(1→3)-GalNAc-

(2) β-Gal-(1→4)-β-GNAc-(1→3)-β-Gal-(1→3)-GalNAc-

(Gal = D-galactopyranose; GNAc = *N*-acetyl-D-glucosaminopyranose; GalNAc = *N*-acetyl-D-galactosaminopyranose.)

The isolation and identification of three H-active fucose-containing oligosaccharides from H-specific substances are now reported. Alkaline degradation was previously observed to give good yields of fucose-containing oligosaccharides from blood-group substances[10], and two of those now described were obtained from the products of partial alkaline hydrolysis. The third was isolated in low yield from a partial acid hydrolysate[8,9] of H-substance.

Alkaline degradation of blood-group H substance (obtained from human ovarian cyst fluid[11]) was accomplished by heating 1 g portions at 60° for 18 h in 50 ml. 50 per cent aqueous methanol containing 2·5 per cent v/v triethylamine. The volatile base was then removed by distillation under diminished pressure, and the residual solution was dialysed against water in a 'Cellophane' sac. After six further treatments of the indiffusible residue in the same way, 70 per cent of the starting material was converted into diffusible fragments.

The diffusible material (2·1 g) from 3 g of H substance was adsorbed on a column (15 × 3·6 cm) of charcoal/'Celite' (1 : 1 w/w). Stepwise elution of the column with water (3·5 l.) and aqueous ethanol (3·5 l. of 1·5 per cent v/v, followed by 3 l. of 2·5 per cent v/v) displaced a complex mixture of monosaccharides, chromogens[12], acidic degradation-products of sugars and other unidentified components. Aqueous ethanol (5 per cent v/v; 6 l.) then displaced a fraction (300 mg) which, after further resolution by preparative paper chromatography, yielded 85 mg of a sugar (I) having $R_{\mathrm{lactose}} = 1{\cdot}55$ in ethyl acetate/pyridine/water (10 : 4 : 3 v/v; solvent *a*), and $M_G = 0{\cdot}47$ in borate buffer at *p*H 10 (ref. 13). It reacted rather slowly on paper with the silver nitrate–sodium hydroxide reagent[14], and with the benzidine–trichloroacetic acid reagent[15] gave a dark brown colour similar to that given by D-galactose.

The sugar (I) was obtained as a hygroscopic glassy solid, having $[\alpha]_D^{23} - 53°$ ($c = 0{\cdot}8$ in water). Chromatography of its acid hydrolysis products indicated the presence of fucose and galactose, and when the glycitol of the sugar, prepared by reduction with sodium borohydride, was hydrolysed and examined, fucose and galactitol were the only detectable products. Analysis of the sugar by the phenol–sulphuric acid method[16] and estimation of its fucose content[17] showed that fucose and galactose were present in equimolar proportions.

That the disaccharide was (1→2)-linked was suggested by its failure to give a red colour with alkaline triphenyl tetrazolium chloride[18], and by its resistance to degradation by alkali[19]. Confirmation of this, together with evidence that the fucose residue was in the pyranose form, was obtained by periodate oxidation. In 0·01 M sodium metaperiodate at 22°, the disaccharide consumed 3·1 mol. of oxidant within the first 4 h and liberated 1·0 mol. of formic acid; further oxidation took place more slowly and after 24 h gave 1·0 mol. of formaldehyde; over-oxidation was observed. Oxidation under the same conditions after borohydride reduction[20] resulted in the rapid (4 h) consumption of 4·9 mol. of periodate and liberation of 0·98 mol. of formaldehyde; there was no over-oxidation.

Disaccharide (I) was therefore identified as 2-*O*-α-L-fucopyranosyl-D-galactose. Comparison of the crystalline 1-benzyl-1-phenylhydrazones (m.p. and mixed m.p. 164°) showed this disaccharide to be identical with a specimen of 2-*O*-α-L-fucopyranosyl-D-galactose kindly supplied by Prof. R. Kuhn[21].

After the displacement of disaccharide (I), the charcoal column was eluted with more aqueous ethanol (2 l. of 5 per cent v/v; 5 l. of 7·5 per cent v/v; and 5 l. of 12·5 per cent v/v). The 12·5 per cent aqueous ethanolic effluent contained 140 mg of carbohydrate material which, after fractionation on paper chromatograms, yielded a component (II; 12 mg) having $R_{\mathrm{lactose}} = 1{\cdot}11$ in solvent *a* and $M_G = 0{\cdot}39$ in borate buffer at *p*H 10. With the benzidine–trichloroacetic acid reagent[15], it gave a golden-yellow colour similar to that given[22] by 4-*O*-β-D-galactopyranosyl-*N*-acetyl-D-glucosamine (*N*-acetyl-lactosamine).

The compound (II) had $[\alpha]_D^{22} - 45°$ ($c = 0{\cdot}5$ in water). Chromatography of its acid hydrolysis products indicated the presence of fucose, galactose and glucosamine, and analysis[16,17,23] showed that these monosaccharides were present in approximately equimolar amounts. However, after reduction of (II) with sodium borohydride, its hexosamine content, determined by the Elson–Morgan method[23] after acid hydrolysis, was negligible whereas the content of galactose and fucose was unchanged. The trisaccharide gave a negative indirect Ehrlich reaction[24], indicating[25] that the reducing terminal *N*-acetyl-glucosamine residue was substituted at position 4.

When trisaccharide (II) was heated in 0·02 N-polystyrene-sulphonic acid[26] at 80°, fucose was rapidly split from the molecule, with the formation of a disaccharide which was chromatographically and ionophoretically indistinguishable from *N*-acetyl-lactosamine and which gave, with the benzidine–trichloroacetic acid reagents, the golden-yellow colour characteristic of that sugar[22]. The disaccharide also gave a negative indirect Ehrlich reaction and slowly underwent further hydrolysis to give galactose and *N*-acetylglucosamine.

In aqueous methanolic triethylamine[9] at 80°, trisaccharide (II) was very slowly degraded, at a rate similar to that of *N*-acetyl-lactosamine, with the liberation of a disaccharide which was completely resistant to further degradation. This disaccharide was chromatographically and ionophoretically indistinguishable from 2-*O*-α-L-fucopyranosyl-D-galactose (disaccharide I), and also resembled that sugar in its behaviour with the benzidine–trichloroacetic acid, silver nitrate–sodium hydroxide, and alkaline triphenyltetrazolium chloride spray reagents.

In 0·01 M sodium metaperiodate at 22°, trisaccharide (II) consumed 3·07 mol. of oxidant within 4 h and liberated 0·96 mol. of formic acid and 0·14 mol. of formaldehyde. Further oxidation under these conditions was very slow. The glycitol of the trisaccharide obtained by reduction with borohydride[20] consumed, under the same conditions, 3·96 mol. of periodate in 4 h and liberated 0·99 mol. of formaldehyde.

On the basis of this evidence, trisaccharide (II) is believed to be *O*-α-L-fucopyranosyl-(1→2)-*O*-β-D-galactopyranosyl-(1→4)-*N*-acetyl-D-glucosamine.

In addition to disaccharide (I) and trisaccharide (II), at least five other fucose-containing compounds were present in the alkaline degradation products of H substance. None of these has yet been fully identified, but one of them (IV), believed to be either a tetra- or penta-saccharide, was obtained sufficiently pure for serological examination (Table 1). Oligosaccharide (IV) was isolated from the 20 per cent v/v aqueous ethanolic effluent of the charcoal column and yielded fucose, galactose and glucosamine on acid hydrolysis; it had $R_{\mathrm{lactose}} = 0{\cdot}73$ in solvent (*a*), and $[\alpha]_D^{22} - 54°$ in water.

The third chemically characterized fucose-containing oligosaccharide (III) was obtained from a partial acid hydrolysate[8,9] of 2·7 g of H substance, and appeared in the 7·5 per cent v/v and 10 per cent v/v aqueous ethanolic effluents from the charcoal–'Celite' column used for fractionation. After purification on paper chromatograms, 5 mg of the sugar was obtained as a syrup. It had $[\alpha]_D^{21} - 36°$ ($c = 1{\cdot}0$ in water) and $R_{\mathrm{lactose}} = 0{\cdot}83$ in solvent *a*. It gave a strong indirect Ehrlich reaction and with the benzidine-trichloroacetic acid reagent gave a greenish-brown colour similar to that given[22] by 3-*O*-β-D-galactopyranosyl-*N*-acetyl-D-glucosamine (lacto-*N*-biose 1) (ref. 27).

Table 1. H Activity of Fragments isolated from Alkaline and Acid Hydrolysis Products of Human H Substance

	Minimum amount of substance giving inhibition (μg/0·1 ml.)				
	Human anti-H	Rabbit anti-H	Eel serum	*Cytisus sessilifolius* reagent	*Ulex europaeus* reagent
Human H substance	0·03	0·07	0·03	0·1	0·07
Alkaline degradation products					
Disaccharide (I) (2-*O*-α-L-fucosyl-D-galactose)	500	1,000	4	2,000	> 2,000
Trisaccharide (II) (*O*-α-L-fucosyl-(1→2)-*O*-β-D-galactosyl-(1→4)-*N*-acetyl-D-glucosamine)	125	63	250	16	32
Oligosaccharide (IV)	—	16	—	8	16
Acid degradation product					
Trisaccharide (III) (*O*-α-L-fucosyl-(1→2)-*O*-β-D-galactosyl-(1→3)-*N*-acetyl-D-glucosamine)	—	32	—	16	16
Control sugars					
4-*O*-β-D-Galactosyl-*N*-acetyl-D-glucosamine	> 2,000	> 2,000	> 2,000	> 2,000	> 2,000
3-*O*-β-D-Galactosyl-*N*-acetyl-D-glucosamine	> 2,000	> 2,000	> 2,000	> 2,000	> 2,000
4-*O*-(*N*-Acetyl-β-D-glucosaminoyl)-*N*-acetyl-D-glucosamine	> 2,000	> 2,000	> 2,000	63	2,000
L-Fucose	> 2,000	> 2,000	16	> 2,000	> 2,000
D-Fucose	> 2,000	> 2,000	> 2,000	> 2,000	> 2,000

(All non-reducing sugar residues are in pyranose form.)

Chromatography of the acid hydrolysis products of (III) indicated the presence of fucose, galactose and glucosamine in approximately equal amounts. However, after reduction of (III) with sodium borohydride, its hexosamine content was negligible, whereas the amounts of fucose and galactose present were unchanged. On mild acid hydrolysis as described for trisaccharide (II), fucose was rapidly split from the molecule with the liberation of a disaccharide which, on further hydrolysis, slowly gave galactose and *N*-acetylglucosamine. The disaccharide was chromatographically indistinguishable from lacto-*N*-biose 1, and gave a strong indirect Ehrlich reaction.

Trisaccharide (III) was extremely sensitive to alkali and on heating at 65° in 0·1 N aqueous pyridine[28] was completely degraded within 30 min with the liberation of free chromogen[12,28] and a disaccharide which was chromatographically and ionophoretically indistinguishable from 2-*O*-α-L-fucopyranosyl-D-galactose (disaccharide I). The liberated disaccharide was identical with disaccharide (I) in its behaviour with the spray reagents named earlier and in its resistance to alkaline degradation.

Trisaccharide (III) is therefore considered to be *O*-α-L-fucopyranosyl-(1→2)-*O*-β-D-galactopyranosyl-(1→3)-*N*-acetyl-D-glucosamine.

The structures of trisaccharides (II) and (III) suggest that, in the native blood-group H substance, the two type of chain (1) and (2), depicted here, have α-L-fucopyranose residues attached to position 2 of their non-reducing terminal galactose residues. Support for this idea arises from a consideration of the probable mechanism by which disaccharide (I) and trisaccharide (II) are formed by alkaline degradation of the specific substance. The chains must presumably be joined to the rest of the molecule by alkali-labile linkages and, once liberated, should undergo stepwise degradation from their reducing ends according to the accepted mechanisms[29] until a relatively alkali-stable linkage is reached. Chains of the first type (1) consist entirely of alkali-labile (1→3)-linkages, and therefore disaccharide (I) probably originated mainly from chains of this type although a small amount could be formed by further degradation of trisaccharide (II). Trisaccharide (II) must originate from chains of the second type (2)—the stepwise degradation in this case being largely arrested by the relatively resistant *N*-acetyl-lactosamine structure. The very alkali-labile trisaccharide (III) does not survive alkaline degradation of H-substance.

The fucose contents (20–25 per cent) of some preparations of H substance are higher than can be accounted for on the assumption that each of the two types of chain carries only one fucose residue. It is likely, therefore, that some of the chains carry additional fucose residues attached to sugar units other than the non-reducing terminal D-galactose residue. The assignment of locations to these additional fucose residues must await the identification of larger oligosaccharides from the alkaline degradation products of H substances.

Anti-H agglutinins of human, animal or plant origin are all, by definition, inhibited in their action on group O red cells by human H substance; they differ, however, in the ease with which they are inhibited by low molecular weight compounds, in the nature of the small units which cause inhibition and in the extent and nature of the changes which can be brought about in H substances before specificity is lost[30]. It is, therefore, important to test isolated fragments with a number of different anti-H reagents. Disaccharide (I) and trisaccharide (II) were tested for inhibition with the following anti-H agglutinins: (1) a human serum from a donor of the 'Bombay phenotype'[31]; (2) an immune rabbit serum prepared by injection of human H substance coupled with the conjugated protein from *Shigella shigae*[32]; (3) a natural eel serum[33]; (4) an extract of seeds of *Cytisus sessilifolius*[34]; (5) an extract of seeds of *Ulex europaeus*[35]. Owing to the limited quantities available for test, trisaccharide (III) and the unidentified oligosaccharide (IV) were examined only with rabbit and plant seed reagents. The results (Table 1) show for the first time inhibition of human and rabbit anti-H sera by low molecular weight fragments. Disaccharide (I) was only slightly inhibitory with the human, rabbit or plant seed reagents, but the trisaccharides were considerably better inhibitors. When both trisaccharides were tested with any one reagent the inhibition titres were the same or differed by only one two-fold dilution factor. The total absence of inhibition with any of the anti-H agglutinins noted for 4- and 3-*O*-β-D-galactosyl-*N*-acetylglucosamine, which are derived from trisaccharides (II) and (III), respectively, by the removal of fucose, once more points to the dominant role of L-fucose in H specificity. The unidentified oligosaccharide (IV) was slightly more active than any of the identified fragments, indicating that a trisaccharide unit does not represent the complete H determinant structure for the reagents examined. The results with the eel serum differed from those of the other anti-H agglutinins in that disaccharide (I), as had been shown previously[5], was a good inhibitor, whereas trisaccharide (II) had considerably less inhibiting potency. The reason for this anomalous behaviour is not clear; but the decrease in inhibiting power with increasing size of fragment, even when the terminal non-reducing units are identical, is consistent with the earlier results obtained with eel serum[5]. The inhibition of the *Cytisus* anti-H reagent by the fucose-containing trisaccharides which did not have terminal non-reducing β-*N*-acetylglucosaminoyl groupings introduces a new aspect into the specificity requirements of this plant seed reagent, and an evaluation of these and the earlier results must await further work. Human anti-Le^{a}, anti-Le^{b}, anti-A or anti-B sera were not inhibited by disaccharide (I) or trisaccharide (II).

Disaccharide (I) and trisaccharide (II) have been detected in the products of alkaline degradation of A and B substances that had H activity, but have not been detected in the products of an Le^{a} substance that showed no H activity (unpublished results). These observations, together with the results of the hæmagglutination inhibition tests, strongly suggest that oligosaccharides (I), (II) and (III) represent integral parts of blood-group H specific determinant structures.

This work was supported in part by a grant from the Medical Research Council.

HÆMOGLOBIN $\mathrm{G}_{\mathrm{ACCRA}}$

By Dr. H. LEHMANN and D. BEALE

Medical Research Council Abnormal Hæmoglobin Research Unit,
University Department of Biochemistry, Cambridge

AND

F. S. BOI-DOKU

Central Clinical Laboratory, Accra

IN 1954 the major hæmoglobin types, A, M, S, C, D, E and F, had been described, and the observation of a new variant, hæmoglobin G (ref. 1), was the first of a series of reports on rarer human hæmoglobins which is still continuing. The hæmoglobin then described—and differentiated from other hæmoglobins with identical or similar electrophoretic properties as hæmoglobin $\mathrm{G}_{\mathrm{Accra}}$—has never been found again, except in the family in which it was originally observed. Hæmoglobin $\mathrm{G}_{\mathrm{Accra}}$ is abnormal in the β-chain[2]. The hæmoglobins with identical electrophoretic and chromatographic properties hitherto examined were α-chain abnormal pigments. There are three: (1) hæmoglobin $\mathrm{G}_{\mathrm{Philadelphia}}$ with which numerous other hæmoglobins observed in West Africa, or in persons of West African origin, are identical[3]; (2) hæmoglobin $\mathrm{G}_{\mathrm{Chinese}}$, which has only been found in persons of Chinese extraction[4]; (3) a hæmoglobin found in a British family, hæmoglobin $\mathrm{G}_{\mathrm{Norfolk}}$[5]. There is one other hæmoglobin named G which also carries its substituted amino-acid residue in the β-chain-hæmoglobin $\mathrm{G}_{\mathrm{San\ José}}$[6], but this pigment differs from hæmoglobin $\mathrm{G}_{\mathrm{Accra}}$ in its electrophoretic properties, and should perhaps have been described under a different letter.

Hæmoglobin $\mathrm{G}_{\mathrm{Accra}}$ is remarkable for the fact that it is the only rare hæmoglobin for which an individual has been described the homozygous state of which could be established on the basis of family investigation and of laboratory findings[7]. This homozygote was found to be healthy without an enlarged spleen, without anæmia, and his red cells were morphologically indistinguishable from those containing only normal hæmoglobin. This was, and still is, in contrast with what is seen in the hæmoglobin S, C, D and E diseases, the only other homozygous conditions for adult hæmoglobin variants so far described.

There was, therefore, a special interest in establishing the precise nature of the amino-acid substitution in hæmoglobin $\mathrm{G}_{\mathrm{Accra}}$. Whatever its nature, it does not have a similar effect on the morphology and, presumably, the life span of the red cell which is produced by the known substitutions in hæmoglobins S, C, D and E.

Amino-acid Substitution in Hæmoglobin $\mathrm{G}_{\mathrm{Accra}}$. Hæmoglobin G was purified from the blood of the homozygote and a peptide-chromatogram (fingerprint) was prepared according to Ingram[8] and Baglioni[9]. It was noted that peptide 6 according to the old numbering system, or tryptic peptide β*Tp*IX according to the new nomenclature[10], was missing and another new peptide was seen instead which had moved nearer towards the cathode (Fig. 1). The new peptide gave a positive colour reaction

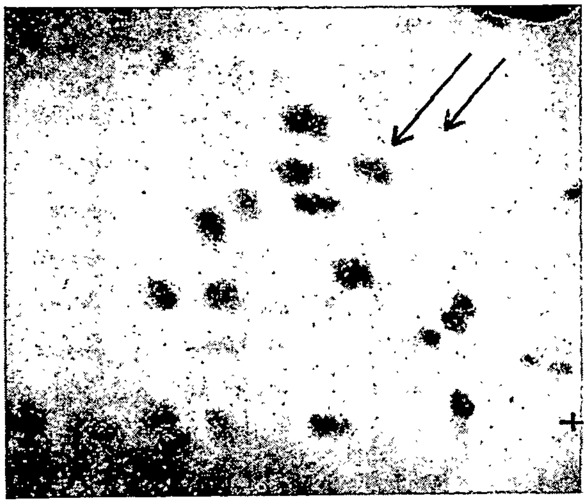

Fig. 1. Fingerprint of the tryptic digest of hæmoglobin G_{Accra}. The right arrow points to the area where β^A*Tp*IX is missing, and the left arrow to the peptide which has taken its place—β^G*Tp*IX. +, Point of application

for histidine[11], as does the β*Tp*IX of hæmoglobin A (β^A*Tp*IX). This peptide contains in hæmoglobin A 16 amino-acid residues[12,13] (Table 1).

Table 1. AMINO-ACID SEQUENCE OF TRYPTIC PEPTIDE IX OF THE β-CHAIN OF HÆMOGLOBIN A

Val–	leu–	gly–	ala–	phe–	ser–	asp–	gly–	leu–	ala–	his–	leu–	asp–	asn–	leu–	lys
67	68	69	70	71	72	73	74	75	76	77	78	79	80	81	82

The NH_2-terminal group[14], was valyl in both peptides, and leucine amino peptidase[4] which splits off amino-acids from the NH_2-terminal part of a peptide chain released valine and leucine in both. As the peptides had arisen from tryptic digestion which implies lysyl or arginyl as the COOH-terminal, and as the colour reaction and amino-acid analysis failed to show arginine[15], lysyl had to be the COOH-terminal group.

Table 2 shows a comparison of the results of quantitative amino-acid analysis on an EEL automatic analyser[16], after the acid hydrolysis of the two peptides from hæmoglobins A and G. It will be seen that the results were the same in both, although the electrophoretic mobility of the G-peptide had indicated that it had a greater positive charge than the corresponding A-peptide. The only explanation was that one of the two aspartic acid residues of β^A*Tp*IX had been replaced by an asparaginyl in β^G*Tp*IX, and that this had been converted into aspartic acid on acid hydrolysis.

Table 2. MOLAR RATIO OF AMINO-ACID RESIDUES AFTER ACID HYDROLYSIS OF TRYPTIC PEPTIDES IX FROM HÆMOGLOBIN A AND HÆMOGLOBIN G_{Accra}

Residues	β^A*Tp*IX		β^G*Tp*IX	
Asp	2·8	2·7	2·6	2·6
Thr	Trace	Trace	Trace	Trace
Ser	1·0	1·2	1·1	1·3
Glu	Trace	Trace	Trace	Trace
Pro	Trace	Trace	Trace	Trace
Gly	2·1	2·0	1·9	2·2
Ala	2·5	2·4	2·3	2·1
Val	1·3	1·1	1·0	0·9
Leu	3·6	3·7	3·7	3·7
Phe	1·0	1·0	1·1	1·2
Lys	0·9	0·9	1·1	1·1
His	0·9	1·1	0·9	1·2

Although on electrophoresis at *p*H 6·4 the mobility of the A peptide is 0·0 and that of the G peptide +0·17 (lysine = +1·0) there seems to be no difference in amino-acid composition after acid hydrolysis.

To investigate this possibility, both peptides β*Tp*IX were eluted with 10 per cent (v/v) pyridine to prevent hydrolysis of asparaginyl, and then digested with pronase for 4 h using the same arrangement as had been used for trypsin, and the resulting smaller peptides and amino-acids were separated by high voltage electrophoresis at *p*H 6·4. Pronase attacks virtually all peptide linkages, although it is relatively inactive towards those which involve aspartic acid residues. Table 3 shows the electrophoretic mobility of these breakdown products, and their amino-acid composition found after acid hydrolysis. This latter method of course converts asparaginyl to aspartic acid. It will be seen that the number of acidic breakdown products in which aspartic acid could be demonstrated differed in the two peptides—four from hæmoglobin A, and three from hæmoglobin G. Three seemed to be the same in both hæmoglobins. Free aspartic acid was obtained from both, and there were two peptides which had nearly the same electrophoretic mobility, and the same amino-acid composition in both. One peptide with the mobilities of −0·77 and −0·78 respectively was hydrolysed into aspartic acid and glycine with aspartyl as the NH_2-terminal residue. The other peptide with the mobilities of −0·64 and −0·62 respectively showed on hydrolysis only aspartic acid, glycine, and leucine with NH_2-terminal aspartyl and COOH-terminal leucyl[14,17]. The sequence 73–75 was therefore the same in both β^A and β^G, namely, asp-gly-leu, and the substitution of aspartyl in hæmoglobin G had to be in position 79 of the β chain.

Table 3. PRODUCTS OF PRONASE HYDROLYSIS OF β^A*Tp*IX AND β^G*Tp*IX

	Mobility*	Amino acids on acid hydrolysis	NH_2-terminal DNP	COOH-terminal
	−1·00	Asp		
	−0·77	Asp, gly	Asp	
	−0·68	Asp		
	−0·64	Asp, gly, leu	Asp	Leu
β^A*Tp*IX	−0·52			
	0·00	Val, gly, leu, asp Ala, phe, ser		
	+0·53	His		
	+0·67	Leu, lys	Leu	
	+1·00	Lys		
	−1·00	Asp		
	−0·78	Asp, gly	Asp	
	−0·62	Asp, gly, leu	Asp	Leu
	−0·54			
β^G*Tp*IX	0·00	Val, gly, leu, asp Ala, ser, phe		
	+0·51	His		
	+0·67	Leu, lys	Leu	
	+1·00	Lys		

* Electrophoretic mobility is measured at *p*H 6·4 using as markers aspartic acid (−1·00) and lysine (+1·00).

From β^A*Tp*IX one other peptide yielding aspartic acid was obtained. It had a mobility of −0·68 but produced aspartic acid only. However, aspartic acid or an asp-asp peptide would have had a mobility of −1·00, hence this peptide had to consist of aspartyl and asparaginyl, and it represented the 79–80 sequence of the β^A-chain, namely, asp-asn.

This peptide was not found in β^G*Tp*IX. However, free asparagine could be demonstrated in the neutral band before hydrolysis. No free asparagine was found in the neutral band of β^A*Tp*IX. From this it could be concluded that the residue next to leucyl in position 79 of the β^G-chain was asparaginyl and hæmoglobin G_{Accra} could be defined as $\alpha_2^A\,\beta_2^{79\ Asn}$.

The sequence asn-asn-leu in hæmoglobin G would explain why pronase digestion produced the peptide asp-asn from β^A*Tp*IX preferably to the free asparagine as obtained from β^G*Tp*IX. In β^G*Tp*IX due to the aspartyl→ asparaginyl replacement the 79–80 linkage was more easily broken because of the absence of an acidic aspartyl residue.

Homozygote. The homozygote is now sixty-four years old, or even a little older, and is physically fit with the exception of a mild hypertension of 160/100 mm mercury.

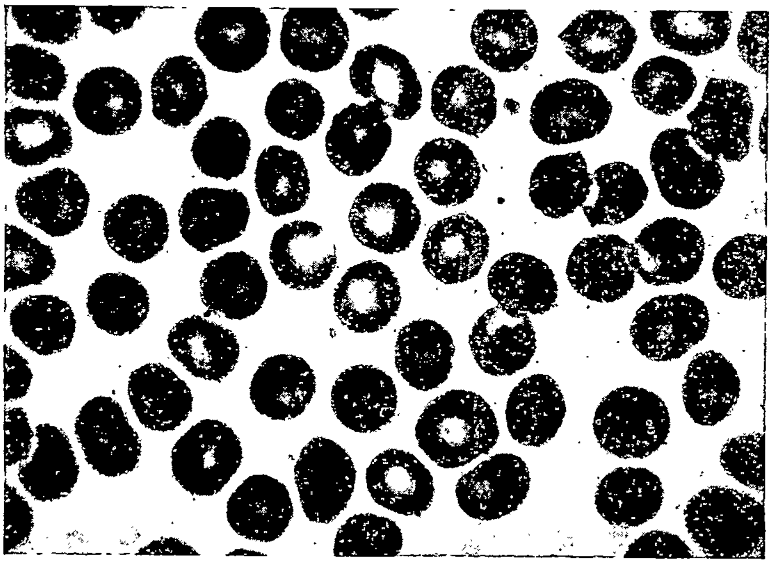

Fig. 2. Stained blood smear of the hæmoglobin-G homozygote. The cells are not hypochromic and the target cells and other abnormal forms associated with the blood picture of hæmoglobin S, C, D and E homozygotes are absent

From 1923 until his retirement in 1963 he worked continually as a printer in the Accra Government Printing Department. Of his twenty children by two wives, all but one is alive and well. The age of the oldest offspring is thirty-six years and the youngest is eleven years old.

His blood shows the following values:

hæmoglobin	12·6 g/100 ml.
red cells	4,500,000/mm^3
packed cell volume	40 per cent

The mean corpuscular values are:

cell volume	89μ^3
hæmoglobin	28 $\gamma\gamma$
hæmoglobin concentration	32 per cent

The red cell fragility showed an almost normal distribution: initial hæmolysis at 0·5 per cent sodium chloride, 50 per cent hæmolysis at 0·415 and 90 per cent hæmolysis at 0·3 per cent sodium chloride. The only unusual feature was that 10 per cent of the cells were still not hæmolysed at 0·3 per cent sodium chloride, and that complete hæmolysis was only achieved in distilled water. There was no enlarged spleen, the red cells were normal in appearance, and there were no target cells. Hæmoglobin A_2 was within normal limits, and no hæmoglobin F was demonstrable. These findings contrast with those in hæmoglobinopathies of the homozygotes for the genes controlling hæmoglobins S, C, D and E. Hæmoglobin $\alpha_2^A\ \beta_2^{79\ \mathrm{Asn}}$ seems to cause no hæmoglobinopathy and the substitution of an asparaginyl residue for an aspartyl in position 79 of the β-chain seems to have no deleterious effect.

Differences in the Morbidity of Hæmoglobin Variants. Of the rarer hæmoglobins only hæmoglobin $\mathrm{G}_{\mathrm{Accra}}$ has so far been seen in the homozygous state. It is probable that many of the other rare hæmoglobins may be similarly harmless, and that there is a relation between the effect a hæmoglobin has on the red cell morphology in the homozygote and the advantage it confers on the heterozygote in natural selection which causes its high frequency in a population.

In the heterozygote for the genes for hæmoglobin A, and for hæmoglobins S, C, D and E respectively, the proportion of the abnormal variant is less than 50 per cent. This has usually been interpreted as the outcome of a difference in the rate of production of normal and abnormal polypeptide chains within the cell[18]. An alternative explanation has recently been proposed by Levere, Lichtman and Levine[19]. From iron incorporation studies in anæmic sickle-cell trait (A + S) carriers they concluded that, in the case of hæmoglobin A + S at least, cells with a wide range of A : S proportions are produced—some with A < S and some with A > S. The first are rapidly eliminated and as a result the final over-all proportion of A : S becomes greater than 1.

In the case of hæmoglobin A + $\mathrm{G}_{\mathrm{Accra}}$ heterozygotes, the proportion of the two hæmoglobins is exactly 1. We have established this by a number of investigations because by ordinary paper electrophoresis at alkaline *p*H the leading (A) band contains about 53 per cent of the total hæmoglobin This proportion is also obtained when an artificial mixture of 50 per cent A and 50 per cent G is submitted to electrophoresis at alkaline *p*H. Furthermore, when open boundary electrophoresis of hæmoglobin from the A + G heterozygote was performed at *p*H 6·5 (ref. 7) and the G fraction was the leading component, the G fraction then amounted to from 50 to 55 per cent of the total pigment.

This equal proportion of A and G in the heterozygote would indicate that there is no elimination of cells with a higher proportion of G than A, and that the whole range of cells survives equally, those with A < G, and those with A > G.

One might predict that other hæmoglobins which show an equal proportion of A and abnormal variants in the hæmolysates from heterozygotes are similarly harmless as hæmoglobin $\mathrm{G}_{\mathrm{Accra}}$. There would, therefore, be a series of hæmoglobin types: (1) Harmless in homozygotes and heterozygotes (heterozygotes show 50 per cent of the abnormal variant): example, hæmoglobin $\mathrm{G}_{\mathrm{Accra}}$. (2) Harmful in homozygotes, harmless in heterozygotes (abnormal variant < 50 > 20 per cent). Hæmoglobins S, C, D and E would belong to this group. (3) Harmful in heterozygotes (abnormal variant < 20 per cent). To this would belong the hæmoglobins which are associated with hæmolysis even in the heterozygote, such as hæmoglobin Köln[20].

The correlation between the morbidity of a hæmoglobin and its molecular structure might throw an important light on the function of hæmoglobin as a whole.

We thank Mr. D. Irvine for valuable assistance, also Dr. G. Braunitzer and his colleagues of the Max Planck Institute für Biochemie, Munich, Germany, for advice and discussion.

INHIBITION OF INTERFERON ACTION BY *p*-FLUOROPHENYLALANINE

By DR. ROBERT M. FRIEDMAN* and DR. JOSEPH A. SONNABEND

National Institute for Medical Research, Mill Hill, London, N.W.7

THE mechanism of action of the antiviral protein interferon[1] is unknown. Incubation for some hours at 37° C is necessary for interferon action since cells treated with interferon and kept at 2° C showed much less resistance to virus infection than cells similarly treated but kept at 37° C (ref. 2), suggesting that an active metabolic process is necessary for development of full antiviral activity. The action of interferon also requires DNA-dependent RNA synthesis on the part of the cell since interferon action was blocked in cells incubated with actinomycin *D* before the addition of interferon[3].

Since RNA synthesis is required for interferon action, it was of interest to determine whether protein synthesis is also necessary. The results of the work recorded here indicate that protein synthesis is required, as interferon action was inhibited in cells incubated with both interferon and the amino-acid analogue *p*-fluorophenylalanine (FPA).

The origin and preparation of the Semliki Forest virus (SFV) pools used in these investigations and the preparation of chick embryo fibroblast (CEF) cultures have been previously described[3]. The virus growth medium consisted of *tris* (0·002 M) buffered Gey's salts with 0·25 per cent lactalbumin hydrolysate, 0·1 per cent peptone, and 2·5 per cent calf serum. During treatment with FPA, buffered Gey's salts only was used for both experimental and control plates. In experiments using FPA the virus growth medium was supplemented with DL-phenylalanine, 100 μg/ml. SFV was assayed and interferon titrated by previously described methods[4]. DL-FPA was obtained from Calbiochem. In all experiments it was used at a concentration of 100 μg/ml.

In order to estimate interferon action in the experiments to be described, CEF's were infected with SFV at a virus plaque-forming unit to cell multiplicity of 20 : 1. This multiplicity of infection was shown in preliminary examinations to yield maximum virus growth at 8 h after infection; in addition, endogenous interferon production had not yet started at that time. After 1 h at 37° for virus adsorption the cells were washed, and the virus growth medium added. After an additional 7 h at 37° the plates were frozen and thawed and the fluids assayed for SFV.

CEF plates were incubated with buffered Gey's salts, or FPA, or interferon, or FPA with interferon. After 5 h, the cells were washed three times and infected with SFV. The results of assays for SFV growth are shown in Table 1. In this experiment pretreatment with FPA only slightly inhibited the growth of SFV. Interferon 1·2 or 0·6 units†, respectively, inhibited virus growth to 5 and 11 per cent of virus controls. On plates incubated with both FPA and interferon, growth of the virus was inhibited, respectively, to 35 and 49 per cent of virus controls. The figures in parentheses in Table 1 and the other tables are the percentage of virus growth in the plates treated with FPA and interferon if the plates treated with FPA alone are taken as controls.

At both concentrations used in this and other similarly conducted experiments, the antiviral action of interferon was inhibited by FPA. Preliminary investigations utilizing tritiated adenosine or leucine labelled with carbon-14 showed that chick cells treated with 100 μg/ml. of FPA had rates of RNA and protein synthesis equal to those of untreated controls confirming the findings of other workers[5].

Table 1. INHIBITION OF INTERFERON ACTION BY *p*-FLUOROPHENYLALANINE (FPA)

Pretreatment of cells*	Yield of SFV at 8 h (PFU × 10^6/ml.)	Virus growth as % of virus control
None (virus control)	215	100
FPA only	210	98 (100)†
Interferon (1·2 units)	11	5
FPA + Interferon (1·2 units)	70	33 (33)
Interferon (0·6 units)	23	11
FPA + Interferon (0·6 units)	105	49 (50)

* Cells were pretreated with buffer, interferon, FPA (100 μg/ml.) or both interferon and FPA (100 μg/ml.) for 5 h, then washed 3 × and infected with Semliki Forest virus (SFV).

† Figures in parentheses represent virus growth in plates treated with FPA and interferon as a percentage of the growth of virus in plates treated with only FPA.

It was of interest to determine whether the inhibition of interferon action by FPA waned with time. CEF's were therefore treated in the same manner as in the previously described experiment. Immediately after the FPA and interferon had been washed off, one set of plates was infected with SFV (Table 2*A*). Another set was allowed to incubate at 37° C for 20 h with virus growth medium and then infected with SFV (Table 2*A*). On the plates infected immediately after the removal of FPA and interferon the inhibitory effect of the FPA was not completely reversed by washing and addition of phenylalanine. The virus growth in plates treated with interferon was 5 per cent of that of the virus control. In plates treated with both interferon and FPA, the virus growth was 13 per cent of the controls, 25 per cent if the inhibition due to FPA was considered.

On plates kept for 20 h before being infected, the antiviral action of the FPA had been almost completely reversed. The effect of the interferon was somewhat less than in the plates infected immediately. The action of FPA to inhibit the antiviral activity of interferon was not reversed by the prolonged incubation between the removal of FPA and interferon and the infection with SFV, since virus growth was increased to 34 per cent of controls in these samples. These results indicated that FPA inhibition of interferon action was persistent.

The preceding experiments suggested that protein synthesis was required for full interferon action. The following experiment was performed to test whether FPA could inhibit the antiviral activity of interferon after protein synthesis had been allowed to proceed for some time following the addition of interferon. CEF's were treated with interferon for 5 h and then with FPA for 5 h. The results (Table 2*B*) showed again that interferon and FPA together had less inhibitory action than interferon alone. When cells were first incubated with interferon and then with FPA, however, the inhibitory action of interferon was the same as in cells treated with interferon and then with *tris* buffered Gey's salts. These results indicated that once protein synthesis had been allowed to proceed after the

† One unit of interferon reduced by 50 per cent the number of vaccinia virus plaques formed on CEF.

Table 2. FPA INHIBITION OF INTERFERON ACTION

Pretreatment of cells*	Yield of SFV at 8 h (PFU × 10^6/ml.)	Virus growth as % of virus control
(A) Persistence of FPA inhibition of interferon action		
SFV infection immediately after removing FPA and interferon		
None (virus control)	39	100
FPA only	20	50 (100)†
Interferon (0·6 units)	2·1	5
Interferon (0·6 units) + FPA	5·0	13 (25)
SFV infection 20 h after removing FPA and interferon		
None (virus control)	32	100
FPA only	29	90 (100)
Interferon (0·6 units)	3·9	12
Interferon (0·6 units) + FPA	11	34 (38)
(B) Lack of inhibition of interferon action by FPA added after interferon		
FPA and interferon added simultaneously		
None (virus control)	52	100
FPA only	45	87 (100)
Interferon (0·6 units)	8	15
Interferon (0·6 units) + FPA	16	32 (36)
Interferon added before FPA		
None (virus control)‡	54	100
FPA, then buffer	33	61 (100)
Interferon, then buffer	6·5	12
Interferon, then FPA	4·3	8 (13)

*, †, See footnotes for Table 1.

‡ Cells were pretreated with FPA (100 μg/ml.) or interferon (0·6 units) for 5 h, FPA or interferon washed off, then buffer or FPA (100 μg/ml.) added for 5 h and washed off. Plates were then infected with SFV.

addition of interferon, the antiviral activity of interferon could not be inhibited by FPA.

FPA is incorporated into proteins which in some instances investigated have reduced biological activity[6]. Since no inhibition of RNA synthesis was found at the concentration of FPA used in this work, the inhibition of interferon action observed indicates that synthesis of protein is required for interferon action.

The findings that interferon did not directly inactivate viruses[2], that a period of incubation at 37° was necessary for interferon action[2], and that protein and RNA synthesis[3] are required for interferon action all indicate that metabolic activity is necessary for interferon action. This suggests that either interferon itself is altered intracellularly to express its antiviral action, or the antiviral action is due to an induced change within the cell. As protein synthesis is required for interferon action, the latter would appear to be the simpler explanation of interferon action, though the former is possible. Interferon could be an inducer of a specific RNA which in turn acts as a messenger for the production of an antiviral protein. Interferon does not stimulate interferon production[7] so that interferon itself could not be the antiviral protein. Since interferon inhibits both RNA and DNA viruses, the proposed antiviral protein might act on RNA synthesis. There is indeed some indication that both crude and purified interferon inhibit total cellular RNA synthesis[8].

After the experiments described in this work had been completed, a paper by Lockart was published with conclusions generally in agreement with those reached by us[9]. The experimental evidence presented by Lockart was, however, open to other interpretations than that protein synthesis was necessary for interferon action.

PROTEIN SYNTHESIS AND TURN-OVER IN CULTURED PLANT TISSUE: SOURCES OF CARBON FOR SYNTHESIS AND THE FATE OF THE PROTEIN BREAKDOWN PRODUCTS*

By DR. R. G. S. BIDWELL

Department of Botany, University of Toronto

AND

DR. R. A. BARR and PROF. F. C. STEWARD, F.R.S.

Laboratory of Cell Physiology and Growth, Cornell University, Ithaca, New York

A PREVIOUS investigation of metabolism and protein synthesis in highly organized plant cells directed particular attention to the contrast between actively growing carrot cells and those in a more quiescent state[1,2]. It was then found necessary to recognize the complexity of the cells, that is, the existence of distinct compartments in which the same metabolite might undergo different reactions. It was also necessary to distinguish between different sources of carbon for protein synthesis and to involve the carbon of protein after turn-over in the general metabolism of the cell to a greater extent than is usually done. A diagrammatic scheme to express these general ideas was formulated (ref. 1, *loc. cit.* Fig. 1).

Further experiments along these general lines have been made from several points of view. (*a*) To bring new evidence to bear on the sources of carbon for protein synthesis; (*b*) to provide new evidence on protein turn-over in these cells and to show the metabolic fate of the carbon so released; (*c*) to contrast the metabolism of asparagine and glutamine in cultured plant cells.

Because *in toto* the experimental data are extensive, they will be presented here in summary form only. The purpose of this summary is to bring the results obtained into the context of present-day thinking on cellular metabolism. This is of particular interest because of present views on the mechanism of protein synthesis, its genetic determination, and the mechanisms which are at present invoked to link the action of the genes—through amino-acid activation, messenger-RNA, soluble RNA complexes, and the template surface—to the actual process of synthesis. It is also necessary to bring these results into harmony with present-day ideas on the path of carbon in the breakdown of sugar through such events as glycolysis, the Krebs's cycle in its various forms, the pentose pathway, etc. To demonstrate these various metabolic pathways they are best investigated separately, whereas in the cell they occur concurrently; but, although all the enzymes for these different systems may be present concurrently, the machinery of the cell may emphasize one part or another. Therefore, these experiments represent a contribution to the understanding of the metabolism of the whole growing cell regarded as an integrated mechanism.

---

* This work represents a collaboration between the Cornell and Toronto Laboratories. The work at Cornell was supported by grants from the National Institutes of Health, U.S. Department of Health, Education and Welfare, to one of us (F. C. S.). This made possible the participation of one of us (R. G. S. B.) as a visiting professor at Cornell University. This also furnished the valuable assistance of Mrs. M. O. Mapes with the aseptic culture methods and provided for a large amount of analytical work under the immediate supervision of one of us (R. A. B.). Part of the work was carried out in the Toronto Laboratories with the assistance of grants from the National Research Council of Canada and the Ontario Research Foundation to one of us (R. G. S. B.).

The new experiments are of three types which will be described in general terms before the results are summarized. Experiments were performed with explanted tissue from the storage root of the carrot under aseptic conditions. The explants were either in the actively growing state (achieved by the use of coconut milk) or in the virtually non-growing state (using the basal medium without coconut milk). These experiments were performed after the explants had become adjusted to these conditions for a period of 8–10 days. In addition, some experiments have been made with freely-suspended, cultured, cells derived from carrot root, potato tuber, tobacco stem, peanut cotyledon and *Haplopappus* shoot. These cells were grown and cultivated by methods which simulate those commonly in use for micro-organisms[3,4].

Summarized Description of the Experiments and Methods

(*A*) *Experiments which bear on the sources of carbon for protein synthesis and its entry into protein from the soluble compounds of the cell. Exp. A*1. The plan of this experiment was simple and direct. The carrot explants were supplied with radioactive sucrose as the major carbon source, either with or without a general non-radioactive source of amino-acids in the form of casein hydrolysate. The objective was to ascertain whether the casein hydrolysate would interfere with the movement of carbon from sugar into the protein, perhaps by furnishing, pre-formed, the obvious amino-acid precursors of protein.

*Exp. A*2. In this experiment 8 parallel samples of tissue explants were exposed to a medium containing sucrose and 7 different amino-acids, but in any one treatment only one of these compounds was radioactive. This design permits one to detect the accessibility of each of these exogenous compounds to the stored soluble compounds of the cell and to the protein.

*Exp. A*3. In this experiment the tissue was furnished with specifically labelled substrates (amino-acids or sugars) to see whether the carbon entered into the amino-acids of the protein by incorporating certain molecules intact or only after their prior metabolism in the soluble phases of the cell.

(*B*) *Experiments which relate to the turn-over of protein and to the fate of the carbon so released. Exp. B*1. In this experiment the carrot tissue was pre-grown for seven days and then treated with ^{14}C-sucrose for another seven days, in order to label the protein heavily. The ^{14}C-substrate was then replaced in the external medium with ^{12}C-sugar, and the subsequent fate of the ^{14}C-labelled soluble compounds and protein amino-acids was determined at five successive intervals during a further period of one week. The thought here was that the soluble pools would rapidly lose their radioactivity, and the fate of any carbon-14 from the radioactive proteins should be detectable. In this way it should be possible to determine the respective contribution to respiration of carbon drawn from the soluble compounds and from the proteins.

(*C*) *Experiments on the respective roles of sucrose, glutamine and asparagine in protein synthesis and respiration. Exps. C*1 *and C*2. In both these experiments ^{14}C-glucose, ^{14}C-glutamine or ^{14}C-asparagine were separately furnished to the tissue. In experiment *C*1 a short pulse of very high specific activity substrate was supplied, and the subsequent progress of the carbon-14 was followed during the metabolism of the cells. The carbon-14 labelled sucrose and glutamine of especially high specific activity were prepared by one of us (R. G. S. B.) by methods developed for the purpose. In experiment *C*2 the carbon-14-labelled source was continuously available to the tissue but at a much lower specific activity. In these experiments, rapidly growing tissue explants, slowly or non-growing tissue explants, and rapidly growing but freely suspended cells from various plants were used.

Methods and Analytical Techniques

In these experiments the compounds to be analysed, whether in the alcohol-soluble fractions of the cells or in the hydrolysates of protein, were first separated by two-directional paper chromatography and their radioactivity was detected by autoradiography. The important compounds were then isolated from the paper, analysed, and their radioactivity determined for the calculation of the specific activity of the carbon. Where necessary, results obtained by the quantitative paper chromatographic methods were compared with, and checked by, data obtained with an automatic Beckman/Spinco amino-acid analyser in series with an automatic recording scintillation counter. The respired carbon dioxide was collected, and its radioactivity determined, after acidification, in an electrometer. All these techniques have been described[2,5-8] and shown to be sufficiently accurate for the purposes of these experiments. It would not be appropriate, however, to present the full details here.

All these experiments were carried out in the dark, in order to avoid the complications of light fixation of

Table 1. Exp. *A*2. Amounts of radioactive carbon (as μg of carbon per 20 explants) acquired by the free (*F*) or protein (*P*) amino-acids during 23 h from various substrates supplied to rapidly growing carrot explants

Compound analysed free (*F*) or protein (*P*) amino-acid	Component of the medium which was radioactive									
	Sucrose		Glutamic acid		Serine		Alanine		Valine	
	F	*P*	*F*	*P*	*F*	*P*	*F*	*P*	*F*	*P*
Aspartic acid	6·7	2·9	1·9	0·46	2·2	0	0	3·1	0	0
Glutamic acid	17·3	Some	11	2·7	0	0	0	11	0	0
Serine	27	9·3	0	0	30	8·0	20	0	0	0
Threonine	0	1·3	0	0	0	0	0	1·6	0	0
Alanine	66	2·6	0	0	0	0	134	11	0	0
Valine	0	4·0	0	0	3·2	0	0	1·8	60	1·0

Interpretation: Note the lack of relationship between the amount of carbon from various sources which entered the free, as compared with the protein, amino-acids. For example, serine supplied carbon for free but not for protein aspartic acid. Alanine, on the other hand, labelled protein aspartic acid but not the free substance. Other similar examples may be seen. Sucrose frequently supplied more carbon to the protein amino-acids than did the corresponding free amino-acids. Also note that alanine tended to supply carbon to a number of the amino-acids and preferentially entered the protein.

Table 2. Exp. *A*3. Radioactivity (mμc. per 20 explants) in free (*F*) and protein (*P*) amino-acids and in the respired carbon dioxide of rapidly growing (plus coconut milk) or slowly growing (no coconut milk) carrot explants, after the supply of ^{14}C-labelled substrates for 24 h

Compound analysed free (*F*) or protein (*P*) amino-acid or CO_2	^{14}C-Substrate supplied and specific activity of the labelled carbon atoms											
	Glutamic acid-1-^{14}C 258 μc./mg C				Glutamic acid-3,4-^{14}C 129 μc./mg C				Glucose-UL-^{14}C 12·5 μc./mg C			
	Fast growing		Slow growing		Fast growing		Slow growing		Fast growing		Slow growing	
	F	*P*	*F*	*P*	*F*	*P*	*F*	*P*	*F*	*P*	*F*	*P*
Glutamic acid	159·4	13·2	24·3	0	358	89·4	47·3	11·4	30·0	13·1	45·8	7·6
Aspartic acid	0	0	0	0	542	13·6	3·8	9·4	21·4	6·6	6·8	6·9
Serine	0	0	0	0	0	0	2·3	0	24·6	11·6	12·0	4·9
Alanine	0	0	0	0	29·8	0	8·3	0	75·0	13·9	31·5	4·1
CO_2	1,164		930		100				936		890	

Interpretation: Note the greater radioactivity of protein amino-acids and the decreased radioactivity of the CO_2 when glutamic acid-3,4-^{14}C was supplied compared with glutamic acid-1-^{14}C. This shows that a major portion of supplied glutamic acid only enters protein after decarboxylation and reconstitution. Also note that glucose-^{14}C generously labelled the protein amino-acids (although its specific radioactivity was very much lower than that of the glutamic acid). Little difference was observed between the results from glucose-UL-^{14}C, as here recorded, and those for glucose labelled in the 1, 2 or 6 position; this shows that all these carbons of glucose are equally accessible for protein synthesis. It is noteworthy that free aspartic acid acquired about 25 times as much radioactivity from glutamic acid 3,4-^{14}C as from glucose-^{14}C yet the resultant protein aspartic acid was only twice as radioactive.

Table 3. Exp. *A*1. Specific activities of carbon in the soluble and the insoluble compounds and the CO_2 of rapidly growing (plus coconut milk) and slowly growing (no coconut milk) explants after 24 h of contact with sucrose-UL-^{14}C (sp. act. of carbon, 337 mμc./mμmol) with or without the addition of 2 per cent casein hydrolysate to the medium. Results as μc. per millimol of carbon

	Rapidly growing explants (plus coconut milk)				Slowly growing explants (no coconut milk)			
	– Casein		+ Casein		– Casein		+ Casein	
Analysed compound	Sol.	Insol.	Sol.	Insol.	Sol.	Insol.	Sol.	Insol.
Sucrose	6·73	–	6·66	–	5·38	–	+	–

CO_2 collected 0–6 h	7·45	–	9·09	–	7·33	–	7·88	–
CO_2 collected 18–24 h	50·1	–	51·8	–	44·3	–	49·6	–

Interpretation: The casein hydrolysate caused no change in the specific activity of the soluble sugar in the cells, but it depressed that of the free amino-acids in the tissue; in spite of this it caused an increase in the specific activity of protein amino-acids and respired CO_2. This effect was more noticeable in the slowly growing tissue because of the much smaller amounts of carbon present in these explants. The casein hydrolysate supplied nitrogen and thereby caused a greater conversion of carbon from sugar into protein amino-acids. Note that alanine in the fast-growing tissue is the only exception to this rule.

$^{14}CO_2$. Experiments showed that dark fixation of carbon dioxide, although it occurred, was very low, and the products did not interfere with the interpretations which have been drawn.

In these experiments all the identifiable sugars and ninhydrin reactive compounds were analysed in the manner described. Records were made of their total carbon and their total radioactivity; the specific activity of their carbon was then calculated. The radioactivity of other carbon compounds (organic acids, peptides, phosphorylated compounds, etc.) was also measured. The movement of carbon to and fro within the soluble pool, and into and out of the protein, was calculated from data obtained on tissue samples taken in time sequence. The data selected to illustrate this article are, therefore, part of a large body of consistent information which is not presented here in full.

Experimental Results and their Interpretation

(*A*) *Evidence on the various sources of carbon and its entry into protein.* The selected results from experiments *A*1–3 are presented in Tables 1–3, and the special points to be noted are enumerated in their legends. The cumulative conclusions to be drawn from these three types of experiments (*A*1–3) are the following:

(i) Sugar from an exogenous source proved to be a more direct source of carbon for the amino-acids in protein than either exogenously supplied amino-acids or the internal pools of stored amino-acids in the cells (Tables 1 and 2).

(ii) Externally supplied amino-acids (that is, in the form of casein hydrolysate) tended to increase the use of ^{14}C-carbon from sugar in protein synthesis. This is because the amino-acids provided a source of nitrogen, but not necessarily of carbon, which increased the overall pace of metabolism and the demand for carbon for protein synthesis (Table 3).

(iii) Although carbon from free glutamic acid can appear in protein, both as glutamic and as other amino-acids, only a small fraction enters the protein directly; a large part of its carbon framework needs to be re-worked in metabolism. The α-carboxyl of glutamic acid largely comes off as carbon dioxide, and the remaining carbon enters the metabolic pool to form carbon acceptors for nitrogen prior to protein synthesis (Table 2).

(iv) The results in Tables 1–3 and the conclusions drawn from the aforementioned (i–iii) require that there are isolated and protected pools of amino-acids in the cell. These are very closely connected with sites of protein synthesis, but they are separate and remote from the pools of the stored amino-acids.

These concepts can be illustrated in the form of a diagram (Fig. 1) the salient features of which are:

(1) The main source of the carbon for protein synthesis is sugar.

(2) The amino-acids which are *en route* to protein and which derive their carbon from sugar are protected or isolated from the storage pools of amino-acids.

(3) Of the amino-acids investigated only alanine is able to bridge these two pools with ease.

(4) Whereas the nitrogen for protein synthesis can be drawn either from external sources or the stored amino-acids the carbon of the stored amino-acids is not so readily used.

(5) From evidence previously reported[1,2] and to be summarized in sections (*B*) and (*C*) which follow it is necessary to postulate some protein breakdown and turnover and that the amino-acids of breakdown contribute to the storage pool and supply carbon for respiration and the evolution of carbon dioxide.

Thus the conclusions *A* i–iv summarized in Fig. 1 are compatible with concepts which emerged from earlier experiments[1,2], with other experiments on leaves[8,9,10], and also with the results from the other experiments, now to be described, in sections (*B*) and (*C*).

(*B*) *Evidence for protein turn-over and the fate of the carbon so released.* The broad conclusions from these experiments are as follows:

(i) The data require that most of the amino-acids of protein must, of necessity, be subject to turn-over. The following type situations which were encountered and which demand this conclusion are:

(*a*) Where the total protein remained approximately constant but its radioactivity changed (Table 4); (*b*) where, during growth, the total protein increased but its radioactivity concurrently decreased (Table 5); (*c*) where the protein remained constant, or increased only slightly, although there was a large increase in its radioactivity which could not be accounted for by a net gain of protein

Fig. 1. The relationships of exogenous sugars and amino-acids to soluble pools in the cell and to protein synthesis

from an obvious radioactive source (because no source of a sufficiently high specific activity was available). It is necessary, in these circumstances, to assume that a protein moiety of low radioactivity was replaced by new protein containing more radioactivity than that which was degraded. This situation (Table 4) is, therefore, a special case of that shown at (*a*).

(ii) It is possible to calculate minimum turn-over rates of protein amino-acids. These are of the general order of 0·2–2·0 per cent per h of the total carbon in the protein; Table 6, however, measures the turn-over of protein carbon in absolute units as affected by the addition of coconut milk. Clearly the coconut milk growth-promoting stimulus also promotes the turn-over.

Table 4. Exp. *B*1. Total carbon (μmols) and total radioactivity (mμc.) and specific activity (mμc./μmol) of carbon in protein glutamic acid of slowly growing carrot explants (basal medium without coconut milk). ^{14}C-sugar was supplied for one week previous to Time 1, ^{12}C-sugar after Time 1. All the data refer to 20 explants

	Time 1 (0 h)	Time 3 (36 h)	Change, Time 1–3
Total carbon	2·94	2·95	+0·01
Total radioactivity	82	97	+15
Specific activity	27·9	32·9	

Interpretation: The specific activity of soluble sugar during Time 1–3 was 29·8 mμc./μmols carbon. The total activity which could have been introduced into protein glutamic acid from sugars by the observed increase of carbon was 0·3 mμc. (0·01 × 29·8) compared with the observed increase of 15 mμc. Therefore, there must have been a loss by turn-over of non-radioactive carbon from the protein to cause the observed increase in specific activity. This kind of result is characteristic of most of the protein amino-acids of slowly growing explants over the several time-intervals during which measurements were made.

Table 5. Exp. *B*1. Total carbon (μmols), total radioactivity (mμc.) and specific activity of the carbon (mμc./μmols) in protein aspartic acid of rapidly growing explants (basal medium plus coconut milk). ^{14}C-sugar was supplied for one week before Time 1, ^{12}C-sugar after Time 1. All the data refer to 20 explants

	Time 1 (0 h)	Time 2 (12 h)	Change, Time 1–2
Total carbon	14·8	17·3	+2·5
Total radioactivity	231	195	−36
Specific activity	15·6	11·3	

Interpretation: Since the total radioactivity in the form of protein aspartic acid decreased by 36 mμc. during the period of observation while the total amount of protein aspartic acid increased by 2·5 μmol of carbon, it is obvious that radioactive carbon in this protein amino-acid must have been replaced as a result of turn-over by carbon of lower specific radioactivity. This kind of result is characteristic of most of the protein amino-acids in rapidly growing explants over the several time-intervals during which measurements were made.

Table 6. Exp. *B*1. Minimum turn-over as μg of rates carbon per 100 explants per day, of protein amino-acids in rapidly growing (plus coconut milk) or slowly growing (no coconut milk) carrot explants, calculated from data of the type shown in Tables 4 and 5

Amino-acid analysed	Turn-over rates of rapidly growing explants between times specified (h)				Turn-over rates of slowly growing explants between times specified (h)			
	0–12	12–36	36–96	96–128	0–12	12–36	36–96	96–128

* Figures derived using equation (2) below. All others derived using equation (1) below.

† Figures between columns were derived from data extending over two time intervals.

Interpretation: These rates were calculated by the method of Hellebust and Bidwell (ref. 6) derived from that of the earlier work (ref. 2) as follows: When turn-over of a protein amino-acid occurs, the observed change in total activity, ΔA, will differ from what would be expected if no turn-over took place, $\Delta C.SA_s$ (change in carbon times specific activity of source carbon), by the amount of activity added or removed by turn-over, $CT\ (SA_s - SA_p)$, where CT is the amount of carbon turned over and SA_p is the specific activity of carbon in the protein amino-acid and SA_s that of the free substance. Thus:

$$\Delta A - \Delta C\,.\,SA_s = CT(SA_s - SA_p) \text{ and}$$

$$CT = \frac{\Delta A - \Delta C\,.\,SA_s}{SA_s - SA_p} \qquad (1)$$

In situations where negative values would be obtained from this formula, as when $\Delta C.SA_s$ was less than ΔA, and SA_p was greater than SA_s, the data require that some protein of low radioactivity was breaking down and being replaced by more strongly radioactive protein. In these circumstances, SA_p approaches zero, and the formula becomes:

$$CT = \frac{\Delta A - C\,.\,SA_s}{SA_s} \qquad (2)$$

These expressions determine the amount of carbon turn-over necessary to account for the observed changes in carbon and activity which occurred. Various values for SA_s are possible; so the value used is the one which gave a minimum figure for turn-over. Equation 2 was used (*) if the data required that carbon leaving proteins did so from a fraction of lower specific activity than the whole. In this case SA_p was assumed to have a value of 0 to give minimum turn-over rates.

It should be stressed that these calculated values for turn-over are minimal; the data permit much higher rates. The turn-over rates recorded here represent values of 0·02–2·0 per cent of the total protein amino-acid per hour, or 0·5–50 per cent per day. Note the greatly increased turn-over rates in rapidly growing as compared with slowly growing explants.

(iii) It is concluded that the breakdown products that result from protein turn-over contribute directly to respiration (Tables 7 and 8) and may account for as much as 27 per cent of the total carbon dioxide which is produced (Table 9).

Table 7. Exp. *B*1. Specific activities (mμc./μmol) of carbon in soluble sugars, protein amino-acids (average), and respired CO_2 of rapidly growing (plus coconut milk) carrot explants at various times following the replacement of ^{14}C-sugar by ^{12}C-sugar

Specific activity of:	Time after removal from ^{14}C sugar 0–12 h	12–36 h	36–96 h	96 h	168 h
Soluble sugars	16·1	10·7	7·8	6·2	3·2
Protein amino-acids	15·2	10·7	7·4	6·9	5·2
Respired CO_2	15·8	11·2	9·1	7·4	5·6

Interpretation: The specific activity of CO_2 was initially below that of the soluble sugars in the tissue, but progressively it rose above this value. This could be brought about by the utilization of a source of carbon for respiration, in addition to the sugars, which in the later time periods had a higher specific activity than sugars, that is, the proteins. The average specific activity of the protein amino-acids was probably slightly below the true value for those protein amino-acids which turned over rapidly because of the presence of some more stable protein of lower specific activity. Another effect of protein turn-over, that is, the decrease in specific radioactivity of proteins with time, is clearly to be seen.

Table 8. Exp. *B*1. Total carbon (μmols per 20 explants) and specific activity of carbon (mμc./μmol) of certain free and protein-bound amino-acids in rapidly growing (plus coconut milk) carrot explants. All data refer to 20 explants

Compound analysed	Time after removal of ^{14}C-sugars 0 h	12 h	36 h	96 h	168 h
Free glutamic acid,					
Carbon	6·75	8·13	7·46	5·10	6·65
Sp. act.	27	33	30	26	19
Free glutamine,					
Carbon	7·87	10·1	–	10·1	9·3
Sp. act.	23·0	30·2	–	30·2	21·0
Protein glutamic acid,					
Sp. act.	15·0	11·9	9·0	5·0	3·3
Free alanine,					
Carbon	26·7	30·6	31·4	32·9	44·3
Sp. act.	19·4	15·5	10·6	8·5	6·6
Protein alanine,					
Sp. act.	17·8	16·4	11·5	8·0	5·3

Interpretation: Note that the total quantity and specific activity of both glutamic acid and glutamine did not change much, while the specific activity of protein glutamic acid decreased greatly with time, largely due to turn-over. Thus the glutamic acid released from proteins by turn-over (having a lower specific activity) did not enter the soluble pool of glutamic acid and glutamine, but must have been converted to CO_2. The specific activity of the soluble alanine pool, on the other hand, closely followed that of protein alanine, showing that they were in equilibrium. The alanine which left the protein could not, however, be freely available for re-synthesis of protein, otherwise turn-over values of 0 would be obtained. Since this is not so (see Table 6), there must have been some preferential conversion of alanine from protein into CO_2.

Table 9. Exp. *B*1. The contribution of carbon derived from protein turn-over to respired CO_2 in rapidly growing (plus coconut milk) or slowly growing (no coconut milk) carrot explants during 12–36 h after replacing ^{14}C-sugar by ^{12}C-sugar in the medium. All results on the basis of 20 explants

	Fast growing	Slow growing
Total protein turn-over*, μg C/h	1·37	0·093
Total respired CO_2, μg C/h	5·0	1·3
Percentage of respired carbon derived from protein turn-over	27	7·2

* Derived from results of the type shown in Table 6.

Interpretation: A substantial percentage of the carbon of respired carbon dioxide was derived from the products of protein turn-over and this was increased by treatment with coconut milk.

(iv) The fates of alanine and glutamic acid after they are released by protein breakdown are different. The alanine passes through a homogeneous soluble pool *en route* to carbon dioxide without any evidence of its protracted storage. The behaviour of the carbon of alanine thus resembles that of sugar much more closely than that of other amino-acids. This alanine pool may well be replenished from sugar and, from the results of experiments *A*1–3 (Tables 1–3), the cellular pools of alanine may well be in dynamic equilibrium with exogenous alanine. By contrast, however, it is necessary to assume that the glutamic acid from protein by breakdown yields carbon dioxide directly, without passing through the main storage pool of glutamic acid which is in equilibrium with glutamine (Table 8).

These conclusions (i–iv) may be illustrated in a diagram (Fig. 2*a* and *b*) and its salient features are as follows:

(1) The amino-acids of the protein are in a state of turn-over.

(2) Carbon released from protein by turn-over contributes to respiration and is evolved as carbon dioxide.

(3) Carbon for the re-synthesis of protein in turn-over is supplied by sugar, the nitrogen being re-cycled.

(4) Glutamic acid released from protein enters a distinct and isolated pool *en route* to carbon dioxide and does not mix with storage glutamic acid or glutamine. By contrast, alanine released from protein mixes freely with the main soluble pool of alanine and also contributes its carbon to a variety of other compounds including carbon dioxide.

(*C*) *Evidence on the respective roles of sucrose, glutamine and asparagine in metabolism, protein synthesis and respiration.* The main conclusions which emerged from these experiments are summarized as follows:

(i) As shown previously, ^{14}C-sugar again labelled the amino-acids of the protein both quickly and generally (Table 10).

(ii) The carbon of exogenously supplied glutamine behaved in the same general way as sugar, and was much more effective than glutamic acid in furnishing carbon to the amino-acids of protein (Table 11; cf. Tables 1 and 2). In this way exogenous glutamine behaved very differently from the storage pool of glutamine which resulted from protein breakdown and to which previous reference has been made (Section *B*, Table 8) and which is less prone to act as a source of carbon for re-synthesis (cf. ref. 2).

Table 10. Exp. *C*1. Amounts of radioactivity (mμc. per sample) in protein amino-acids of slowly growing explants (no coconut milk), rapidly growing explants (plus coconut milk) and cultured cells of carrot, following 4 h of exposure to ^{14}C-sucrose of very high specific activity. (Specific activity of supplied sucrose, 450 mc./millimol). (Samples consisted of 10 slowly growing explants, 5 fast growing explants or 100 mg of free cells)

Compound analysed	Tissue type	Time in hours, after removal of ^{14}C-substrate 0	8	20	44
Aspartic acid	Slow growing	0	3·1	3·9	5·0
	Fast growing	–	6·8	11·4	10·0
	Free cells	2·03	5·25	3·48	2·90
Glutamic acid	Slow growing	1·5	5·0	9·7	17·0
	Fast growing	–	16·8	22·2	16·0
	Free cells	5·51	1·75	0·58	0
Alanine	Slow growing	0	0	0	2·5
	Fast growing	–	1·1	15·6	11·2
	Free cells	0	+	4·64	0
Valine	Slow growing	0	0	0	0
	Fast growing	–	19·4	21·0	13·0
	Free cells	0	+	7·25	2·90

Interpretation: The proteins of the slowly growing explants acquired radioactivity slowly and continuously throughout the experiment. The proteins of fast growing explants first acquired radioactivity, then lost it, showing that rapid turn-over of the proteins was taking place. The behaviour of cultured cells was similar to that of rapidly growing explants, but was greatly accentuated.

(iii) Asparagine behaved very differently from glutamine. Although it reached high concentrations in the soluble fraction of the cells, it contributed its carbon almost exclusively to aspartic acid in the protein. Other protein amino-acids acquired small amounts of carbon-14 from asparagine, but only after long exposure. Therefore, it is very clear that asparagine and glutamine stand in quite different relationships to protein synthesis in these cells (cf. Table 11).

(iv) These experiments also furnish supplementary evidence for protein turn-over in growing tissue explants and especially so in free cells, whereas turn-over in the non-growing explants took place only slowly, if at all (Table 10).

Concluding Remarks

The major general points to be emphasized are as follows.

Protein turn-over has again been demonstrated to be a general feature of the intermediary metabolism of plant cells during their growth, but it is not confined to cells in active proliferation and growth, for it also occurs in cells in a more quiescent, non-growing state. The evidence for protein turn-over, at minimum rates of the order of 0·2–2·0 per cent per h, seems unequivocal. An alternative interpretation that might have been raised can be dismissed. This is that the protein breakdown occurs in different cells from the protein synthesis. This would

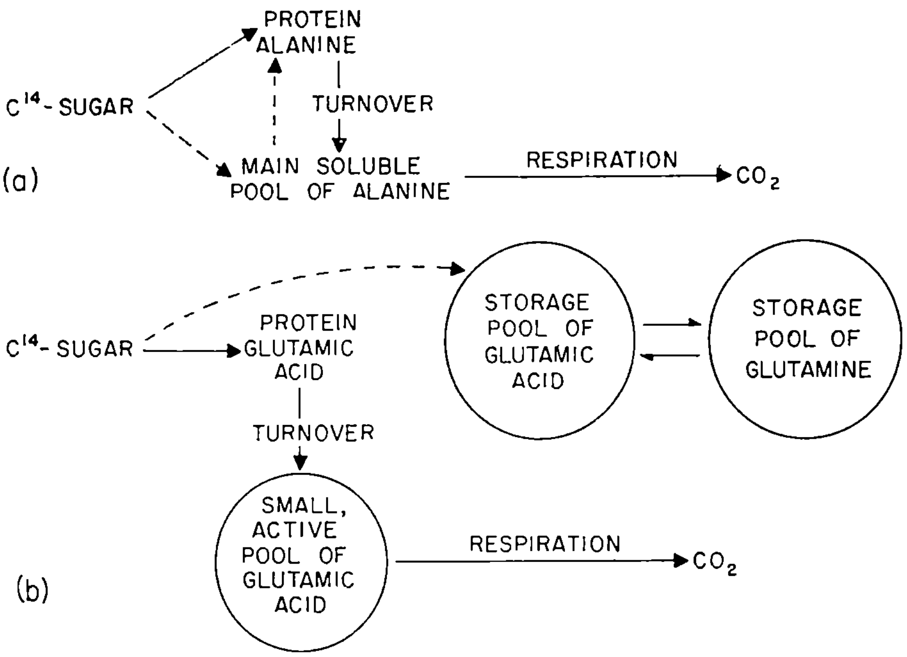

Fig. 2. The relationships of endogenous alanine (*a*) and endogenous glutamic acid and glutamine (*b*) to soluble pools and to protein turn-over and respiration. Distinct and immiscible pools are shown encircled. Dotted lines indicate leakage or minor pathways

constitute protein turn-over within the tissue mass though not in individual cells. However, this would imply the irreversible change, senescence, or death of cells at a minimum rate of 0·2–2·0 per cent per h. This does not occur in the slowly growing explants on basal medium, which do exhibit turn-over, and certainly not in the rapidly growing explants in the exponential phase of their growth. Therefore, neither simple accretion of new protein during growth, nor irreversible loss of old protein during senescence and death of some cells, can account for the results. Cyclical protein turn-over, that is, breakdown and re-synthesis, is the only possible explanation.

It is again found that the carbon of protein, via turn-over, becomes much more involved in the processes of respiration than is usually considered. Sharp distinctions are again made between sugar as the most effective source of carbon for protein synthesis in the intact cells and the stored, free amino-acids as the most obvious source.

Sugar, which either enters the cells exogenously or is locally produced, is metabolized and thereby produces carbon skeletons for the formation of the amino-acids out of which protein is built. The nitrogen either comes from nitrate reduction or ammonia or is donated by nitrogen-rich compounds. The amino-acids used to build protein are, however, strictly localized and do not mix with other pools in the cell. Protein synthesis, as it is at present conceived, proceeds from these protected pools of amino-acids which are derived from sugar in this way. The breakdown products from protein turn-over, some of which are re-worked to form the nitrogen-rich storage products, enter separate pools or phases from the amino-acids which are *en route* to protein. Much of the carbon of these stored amino-acids (which do not build up conspicuously during growth) is eventually converted to carbon dioxide during respiration and may account for more than 25 per cent of the total carbon dioxide, whereas their nitrogen becomes re-available for protein synthesis (ref. 1, *loc. cit.* Fig. 1). Within this general scheme different behavioural patterns of individual amino-acids have been encountered, such as the contrasted behaviour of alanine and glutamic acid and its amide glutamine as shown in Fig. 2 and the sharply contrasted roles of asparagine and glutamine as shown in Table 11.

In all these respects, therefore, it is necessary to add to conventional ideas of the paths of carbon in respiration and the mechanisms of protein synthesis some further concepts which involve the organization of the cells. The localization of given intermediates in special compartments in the cells accounts for their distinctive roles in metabolism. The many interactions between distinct parts of the cells here postulated and between different metabolic processes now help us to account for the difficulties which have so often been encountered in reproducing some of the major synthetic attributes of intact cells in cell-free systems. This has been especially notable in the case of protein synthesis. Cell-free systems by their very nature can include only a part of the machinery of the intact cell, so that any essential features which depend on interactions between its parts are obviously lacking. The localization of function and of segregated pools of metabolites in distinct compartments or organelles obviously provides for 'division of labour' within the cell; it also provides for the degree of complexity required of the organized growing cell, but it also involves a need to bring these diverse activities under co-ordinated and regulatory control.

It is, therefore, now necessary to relate modern concepts of metabolism, as conceived in terms of gene-controlled enzymes, to the organization of the cells within which the reactions occur and by which they are modulated. Present views on molecular biology may go far to reveal the individual reactions of cells and the way these capacities are inherited. Much more than this is, however, necessary to understand how cells work as integrated metabolic

Table 11. Exp. *C*2. Amounts of radioactivity, as mμc. per 5 explants, which entered the protein amino-acids of rapidly growing (plus coconut milk) carrot explants during 48 h from exogenous ^{14}C-labelled sucrose, glutamine or asparagine. (Specific activity of carbon in sources, 0·66 *μ*c./*μ*mol)

Compound analysed	^{14}C-substrate supplied Sucrose	Glutamine	Asparagine
Aspartic acid	40	32·4	40·8
Glutamic acid	144	33·6	4·0
Serine	40	12·0	2·0
Glycine	8	24·0	2·4
Alanine	56	0	2·8
Valine	56	0	0
Leucine	84	16·0	0
Phenylalanine	60	0	0
Proline	40	22·8	0
Threonine	0	13·8	0

Interpretation: Note the relative ease with which sucrose and glutamine label a wide range of protein amino-acids in comparison with the weak labelling from asparagine, except in aspartic acid. Similar results were obtained for different time intervals and a variety of other tissues and cultured cells. Whereas alanine and phenylalanine in the protein were readily labelled from sugar, they were not labelled by glutamine.

machines, and to show how, during active growth or steady states, their metabolism is brought and kept under regulatory control. These major problems of cellular organization need to be solved to bridge the gap between our knowledge of molecules and reactions in homogeneous systems and of the heterogeneity which is necessary for life. In doing this, a place must be found for the regulatory role of stable substances, not of nuclear origin, which may even be supplied exogenously to the plant cells within which they can control the pace of growth and protein synthesis.

Though the very recent article on "What is Heredity?" by Dr. Dean and Sir Cyril Hinshelwood[11] can only be cited, it contains many penetrating observations on the role of structural organization and cytoplasmic architecture that seem relevant even to the very different kind of system which is here discussed.

A LEUCINE AMINOPEPTIDASE POLYMORPHISM IN *Drosophila buskii*

By F. M. JOHNSON and R. K. SAKAI

Department of Genetics, University of Hawaii, Honolulu

THROUGH the use of the starch-gel zymogram technique[1,2] a wide variety of electrophoretic enzyme variations have been described in recent years. In *Drosophila melanogaster* electrophoretic variations in the esterases have been found by Wright[3] and by Beckman and Johnson[4]. These variations were found to be controlled by two independent loci on the third chromosome. Three different phenotypes can be observed for each of the esterase systems: *F/F* (a fast-moving component), *S/S* (a slow-moving component) and *F/S* (the heterozygous type with both fast- and slow-moving components). Crossing experiments suggest that about 20 recombination units separate the two esterase loci.

Another biochemical variation in *Drosophila melanogaster* is the leucine aminopeptidase (Lap) system described by Beckman and Johnson[5]. Leucine aminopeptidase is operationally defined as an enzyme that hydrolyses L-leucyl-β-naphthylamide. In the work done by Beckman and Johnson, two independent Lap systems were found and were observed to be controlled by two closely linked genes. Not a single case of recombination was found in their investigation.

This preliminary report is also concerned with the enzyme leucine aminopeptidase but in a relative of *Drosophila melanogaster*, *Drosophila buskii*.

The stocks of *D. buskii* used in this investigation were obtained from Dr. M. Wheeler of the University of Texas, who is at present engaged with the *Drosophila* research group in the University of Hawaii. The flies were cultured on a medium containing the following ingredients: water, 1,000 ml.; agar, 10 g; banana, 300 g or 400 ml.; yeast, 50 g; cornmeal, 30 g; propionic acid, 5 ml.; ethanol, 5 ml.

These flies were originally collected from the Tantalus area in Honolulu, Hawaii, during July–August 1963. The cultures were started from relatively small numbers of individuals, but were mass transferred when fresh medium was required. Approximately 22 generations had elapsed between collection and examination for leucine aminopeptidase.

Single *Drosophila* individuals (larvæ, pupæ or adults) were placed on a microscope slide and homogenized with a lancet in a small drop (approximately 0·02 ml.) of distilled water. The homogenate was absorbed into a 4 mm × 6 mm piece of filter paper and inserted into a vertical slot in the starch gel. In order to prevent streaking from cell fragments in the electrophoresis, a small piece of thin paper (single layer of 'Kleenex Celluwipes', Kimberley-Clark Corp.) was first placed over the drop of homogenate to act as a filter.

The discontinuous buffer system of Poulik[6] was used and the electrophoresis was carried out for 2·5 h or until the brown borate front zone had migrated 7 cm past the sample slot. A voltage gradient of 6–8 V/cm at room temperature was used.

On completion of the electrophoresis the gels were sliced horizontally and one-half stained for 2 h in a solution consisting of 40 mg L-leucyl-β-naphthylamide, 50 mg Black K salt and 100 ml. 0·2 *tris*maleate buffer, *p*H 5·2. The other half of the gel was stained with a non-specific protein dye, amido black. After staining, the gels were fixed and preserved in a solution of acetic acid, methanol and water (1 : 5 : 5).

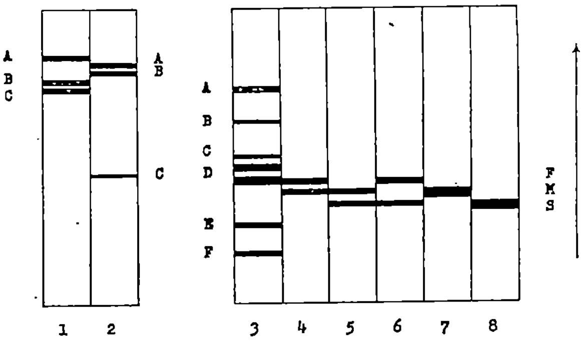

Fig. 1. Diagrammatic comparison of isozyme variations in *D. melanogaster* and *D. buskii*: Sample (1), major protein zones of *D. melanogaster* as revealed by amido black staining; (2), major protein zones of *D. buskii*; (3), lap zones of *D. melanogaster* (a heterozygote for the D zone is shown); (4–8), some different lap types of *D. buskii*. The arrow shows the direction of migration

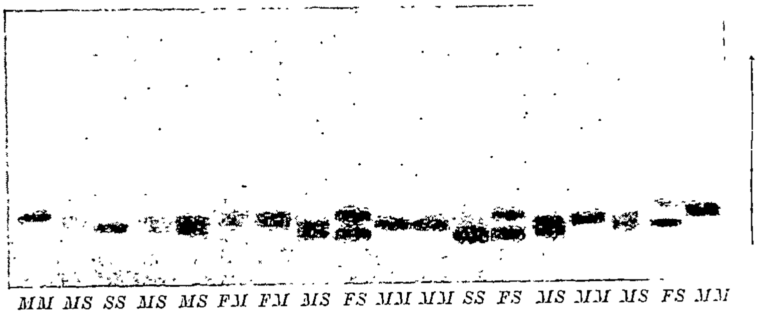

Fig. 2. Photograph of typical electrophoretic run showing some of the various Lap types in *D. buskii*. Genotypes are below each sample. The arrow indicates the direction of migration

When single individuals are run in the electrophoresis, a number of different[1] Lap patterns are observed (Figs. 1 and 2). Either a single band or two bands may be present in any of three different positions in the starch gel. These three positions are designated *F* for the fastest band, *S* for the slowest band, and *M* for the band of intermediate mobility. Preliminary experiments indicate that individuals with only a slow band are homozygous (Lap^S/Lap^S). Similarly, Lap^M/Lap^M is thought to produce an enzyme of intermediate mobility and Lap^M/Lap^S both an intermediate and a slow band. In like manner it is suggested that the other patterns, where a single zone is present, is due to a homozygous Lap gene, and where two zones are present, the pattern is due to heterozygosity at the Lap locus. Thus the basis of determination of the Lap type is apparently three co-dominant alleles. Preliminary examination of our cultures indicates that the gene frequencies of *F*, *M* and *S* are 0·130, 0·538 and 0·332 respectively. All the patterns described for *D. buskii* have been observed in the larval, pupal and adult stages whereas in *D. melanogaster* strong Lap activity is found only in pupæ[6].

Leucine aminopeptidase is a proteolytic enzyme that is probably of considerable importance in protein degradation during metamorphosis. The fact that one species produces the enzyme in all developmental stages while in another enzyme production is limited to the pupal stage suggests that different evolutionary pathways have been followed. It seems in general, though this is but a preliminary finding, that continued investigation of enzyme variations, through the use of starch-gel electrophoresis, promises to be a powerful tool toward greater understanding of phylogeny especially when it involves such a genetically well-known group as the *Drosophila* species. Furthermore, the presence of an apparently tri-allelic polymorphic system in *D. buskii*, in which the three homozygous types as well as the heterozygotes are easily recognized, can be of considerable importance in the investigation of certain population genetic models.

BOUND WATER, METABOLITES AND GENETIC CONTINUITY

By PROF. S. J. WEBB

Department of Bacteriology, University of Saskatchewan, Saskatoon

PREVIOUS work has shown that there is a parallelism between the mechanism by which desiccation[1–3], ultraviolet light[4] and X-ray[5] damage both bacterial cells and viruses. These experiments suggested that the removal of water bound to cell macromolecules causes a change in the structure of the latter which leads to death of the cell. This hypothesis was supported further when it was found that the protection of a cell by an added chemical relied on the presence of strategically placed $—NH_2$ or —OH groups in the structure of the added molecule with inositol the most efficient all-round stabilizer[1–5]. Using this latter compound, the only function of the cell protected appeared to be its ability to synthesize new proteins[6,7] and it was assumed that inositol reacted in some way with the nucleoproteins. This assumption was rendered more plausible when Rous sarcoma virus (RSV) was found to be protected by inositol both against desiccation[8] and ultra-violet radiations[9] and that this compound appeared able to displace nucleoproteins from a dried cell[10]. During the course of these investigations it was noticed that colour mutant cells appeared in greater numbers when cells were damaged in the dry state at certain levels of relative humidity[4], which suggested that desiccation alone could bring about mutation. Since inositol appeared able to prevent this particular mutation, and in the light of its protective ability against ultra-violet and X-rays, it was assumed that death and mutation were part of one process and that inositol and other small molecules were responsible for maintaining the biological integrity of large conjugate molecules. It was of interest then to examine further the mutagenic action of desiccation, and it is the purpose of this article to describe some rather remarkable findings which seem to shed some light on the mechanism of enzyme induction, protein and DNA replication, and the method by which the DNA code functions.

Cultures of a *Lac*$^+$ strain of *Escherichia coli* were grown on either (*a*) a minimal medium containing 0·25 per cent ammonium sulphate plus 2·0 per cent glucose in 0·01 M phosphate buffer *p*H 7, or (*b*) a full medium containing 2·0 per cent glucose, 1·0 per cent casamino acids, and 0·05 per cent yeast extract. After growth for 24 h at 37° C on a rotary shaker the cells from 20-ml. aliquots either aerosolized directly (slurry), washed once in 0·85 per cent NaCl and once in distilled water and resuspended in the mother liquor (supernatant) or in 20 ml. of a solution of inositol or lactose. In the case of the adaptation experiment, film drying was used as previously described[6,7]. Aerosol samples were collected in saline and plated on: (*a*) the minimal medium, (*b*) the full medium and (*c*) lactose–eosine methylene blue agar. After growth for 18 h, large plates of (*a*) containing approximately 1,000 colonies were photographed and overlaid with agar containing a mixture of 16 amino-acids.

The medium in which the cells were grown had a significant effect on their stability in aerosols. Those grown in minimal medium were far more resistant to desiccation than those grown on the full medium, and apparently the addition of the minimal medium spent culture fluid offered protection to both kinds of cells. The interesting point seemed to be the considerable stability of the minimal medium grown cells aerosolized as a slurry; they displayed almost the same stability as those cells to which inositol had been added (Table 1). It was evident, also, that the added protection afforded cells by growth in minimal medium resulted from the extra metabolites produced. However, since washing removed some of the protection their position in the cell as a result of physiological processes was assumed to be important.

It was noticed that the recovery of cells grown in the full medium after aerosolization was always slightly larger if the cells were plated on a full medium, and since desiccation damage appeared to result in the inability of cells to

Table 1. EFFECT OF GROWTH AND PLATING MEDIUM ON THE DEATH-RATE OF AIR-DRIED *E. coli*

Aerosolization conditions	Death-rate (*K*)* *MM* (plating)	Death-rate (*K*)* *FM* (plating)
FM cells in water	0·048	0·042
MM cells in water	0·026	0·021
FM cells in slurry	0·033	0·028
MM cells in slurry	0·009	0·009
FM cells in *MM* spent culture fluid	0·010	0·012
MM cells in *FM* spent culture fluid	0·021	0·018
FM cells in 5 per cent inositol	0·006	0·007
FM cells in 2 per cent arginine	0·018	0·017

FM, full medium; *MM*, minimal medium

* Death rate calculated from $N_t = N_0e^{-Kt}$.

synthesize protein it seemed likely that some specific blocks might have developed. This was found to be true when overlays of amino-acid agar allowed the development of a few more cells which on sub-culture proved to have a genetic block in amino-acid synthesis. The specific nature of these blockages was not determined as it had little bearing on the objective of the investigations. When this phenomenon was investigated further, the number of these mutant cells was found to be dependent on the relative humidity at which the airborne cells were held (Fig. 1). Therefore, since relative humidity is known to control the bound-water content of the cells[1,3] and as these mutants did not appear in minimal medium slurries or when inositol was added, both bound water and metabolites appeared to be involved, not only in preserving the viability of the cells, but also in preventing mutation. In an attempt to clarify the situation the ability of cells to produce adaptive β-galactosidase was studied using the spectrophotometric method with *O*-nitrophenol-βD-galacto-pyranoside. As had been reported earlier[6,7], cells dried at 40 per cent relative humidity from water showed reduced ability to manufacture the enzyme. However, if inositol, lactose or glucose was added to the cells prior to aerosolization this loss of inducibility was prevented, even though the latter two compounds only reduced the death-rate of the full medium grown cells from 0·042 to 0·021 and 0·028 respectively. Similarly, cells grown in minimal medium and aerosolized as a slurry retained their inducibility. It now seemed clear that inositol and cell metabolites prevented damage to those molecules concerned in protein synthesis, but why lactose and glucose should perform this function also was not immediately clear. Since it is well known that glucose will inhibit β-galactosidase syntheses, its ability to preserve the adaptive powers of the cell had to reside in a competitive association with another molecule and presumably this association also led to the preservation of the integrity of this associated molecule. In the light of the previous findings with the occurrence of amino-acid deficient mutants it was considered possible that a combination between the sugars or inositol and DNA might be responsible, hence it appeared logical to look for sugar-deficient mutants in the form of lactose negative (*Lac*⁻) cells. The initial experiments with cells grown on minimal or full media and plated on 'EMB–lactose' medium failed to demonstrate mutants in any significant numbers. Then it was realized that glucose was, in fact, a starting point of metabolism and that some glycolytic enzymes might be adaptive. The full medium was changed, therefore, and, instead of glucose, sodium acetate or succinate was added. After several sub-cultures in the above medium the cells produced *Lac*⁻ mutants in relatively large numbers on drying, and since glucose, lactose or inositol appeared able to prevent their occurrence (Fig. 2) it could only be assumed that a combination between these additives and DNA prevented this particular mutation.

In a later series of experiments the airborne cells, aerosolized in minimal medium or distilled water, were irradiated for 5 min with a G.E.R.S. sunlamp, and while all the phenomena described here for unirradiated cells were observed the relative humidity range at which the mutants appeared was much sharper (Fig. 1).

Since 'early' protein synthesis is required for bacteriophage DNA replication, and these proteins are considered to be the DNA polymerase and enzymes concerned in the syntheses of hydroxy-methyl-cytosine, it appeared likely that drying might interfere with a similar system in uninfected cells. Cells of a thymine-deficient *E. coli* were grown in a medium containing a mixture of amino-acids 1·0 per cent, glucose 1·0 per cent and a mixture of the five nucleic acid bases. 10 ml. aliquot were washed in phosphate buffer and allowed to starve in buffer for 1 h. 1 ml. of these cells was then placed in the same medium as above, except that each cold compound was replaced by the carbon-14-labelled metabolite under investigation.

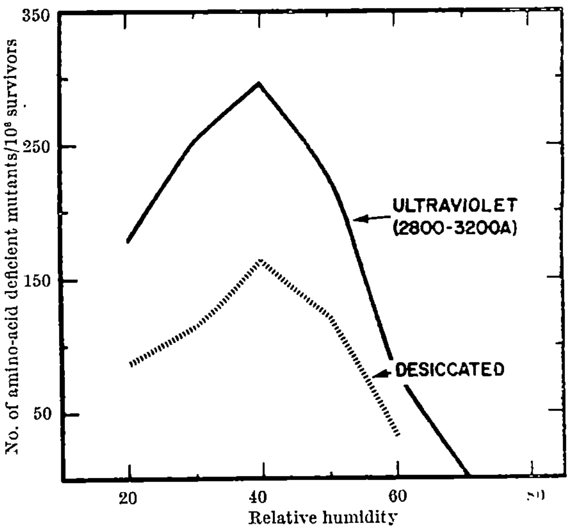

Fig. 1. Effect of relative humidity on the production of amino-acid dependent mutants of *Escherichia coli* by desiccation and ultra-violet light

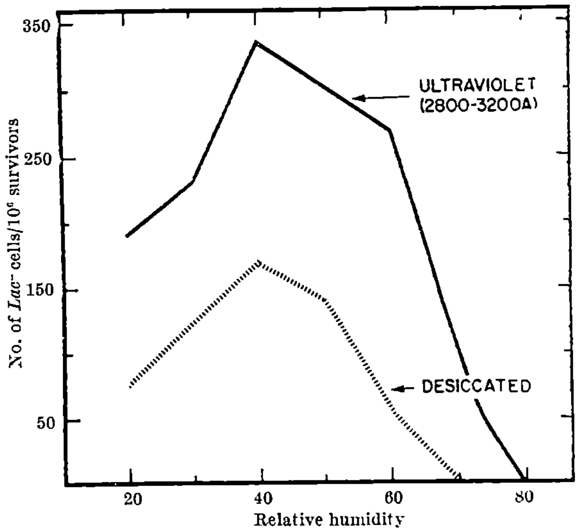

Fig. 2. Effect of relative humidity on the production of lactose negative mutants of *Escherichia coli* by desiccation and ultra-violet light

From these experiments it was clear that there was an immediate uptake of uracil, amino-acids and lactose which lasted for about 10 min during which time there was no thymine uptake. β-Galactosidase activity occurred, however, along with the 'early' proteins. In the next 10–20 min the uptake of the former three components almost ceased, but DNA synthesis occurred very rapidly, then, as this slowed the uptake of amino-acids, uracil and β-galactosidase activity increased again.

This behaviour strongly suggested that early protein synthesis was required for DNA replication in a normal cell even when there was no change in medium. Dried cells protected with inositol or minimal medium supernatant behaved as the controls, but the pattern of events with unprotected cells was somewhat confusing. The initial uptake of uracil by these cells was far greater than the controls, yet there was no speed-up of either amino-acid uptake or β-galactosidase activity; in fact the latter two were considerably delayed. This simulated earlier findings[10] where this large uracil uptake was found to be correlated not with survival but with death. Apparently the delay in enzyme synthesis and DNA replication is connected with the survival mechanism, and it seems reasonably clear that this delay is evident only during the first 30 min; from then onwards the cells behave

Table 2. Syntheses of Protein and Nucleic Acids by Air-dried and Normal Cells of *E. coli*

Compound examined		Time (min) 5	10	15	30	45	60

normally. The most significant finding would seem to be the fact that a definite amount of amino-acid uptake is necessary before DNA replication occurs as well as the small lactose uptake during this time.

Because of the apparent role of bound water in maintaining the biological integrity of macromolecules, and since most chemical carcinogens as well as ultra-violet and X-rays could be considered as molecular desiccants they would compete with or remove bound water from, Swiss mice were inoculated with normal spleen and thymus cells obtained from young mice. Some of the animals were given undried cells washed in basic salt solution, and others cells dried for 30 min at 40 per cent relative humidity. After 12 months, surviving animals were killed, autopsied and the malignant nature of each tumour confirmed by histological examination. All the leukæmias could be classified as lymphoblastic lymphomas with thymus, lymph nodes, liver, spleen and kidney generally involved.

The results given in Table 3 show clearly that in those groups given dried cells the number of animals with tumours jumped from 11·0 to 42 per cent, and the total tumours from 12·6 to 56 per cent. Most of the increase, however, was in the incidence of leukæmia.

Table 3. Incidence of Tumours in Swiss Mice inoculated with Dried or Non-dried Normal Cells

Group	No. of animals	Animals with tumours (per cent)	Total No. of tumours	Total tumours (per cent)
Controls	72 (4)†	11·0	5 (*L*)* 4 (*MC*)	12·6
Dried	50 (4)	42·0	22 (*L*) 6 (*MC*)	56·0

* (*L*) = leukæmias; (*MC*) = mammary carcinomas.

† No. of separate groups set up.

Previous work over many years has demonstrated that the aerosol is an excellent and unique way of investigating the role of bound water and chemicals in the maintenance of molecular structure and integrity of metabolic processes[1-7]. The results presented in this article tend to support the hypothesis that bound water and some small molecules, with strategically placed groups, maintain biological integrity. One could argue that an association between an enzyme and its substrate, or the attachment of a substrate to RNA, leads to a more stable cell. However, if DNA is the master molecule, damage to either a protein or RNA should be reparable. This is perhaps why protein synthesis in the damaged cells is delayed since new messenger RNA will be required. There seems to be no doubt that both RNA and DNA can be protected by inositol, and the latter by metabolites also. It is possible, therefore, that some of the proteins synthesized during the first 10 min are manufactured by the existing RNA, and the preservation of its structure may help to prevent death of the cell, provided no drastic change has occurred in the DNA.

Whether the observed increase in incidence of tumours represents an acceleration of tumour development, or an actual induction, either by virus release or mutation, remains to be determined. However, the latter hypothesis is favoured in view of past experience with desiccated bacterial and mammalian cells and because the observed increases go well beyond the normal incidence found in these mice. Unless one assumes that enzymes and RNA are responsible for genetic continuity, the foregoing arguments do not explain the observed mutation in bacteria and their prevention by inositol or metabolites. A more plausible explanation seems to be that mutation is one step towards death, or, in other words, damage to DNA leads to mutation, then death. If one makes this assumption, then it becomes necessary to explain why small molecules preserve the integrity of a gene. Proteins are known to be bound to the 'outside' of the DNA molecule, and from time to time there have been reports of sugars and even inositol being associated with this molecule; water certainly is. Also, cells grown on minimal medium are known to be independent of the amino-acids usually necessary for the production of back mutant prototrophs[11], and an explanation of these facts now appears possible from the data presented.

The types of investigations we have carried out in our laboratories are perhaps an unusual approach to the problem of genetic continuity; but the implications from stability studies nevertheless seem quite valid. In order to explain the results, however, one must view the whole picture of experimental facts. (*a*) Desiccation at certain relative humidity-levels, ultra-violet irradiation and X-ray are all lethal and mutagenic. (*b*) The efficiency of the latter two agents on semi-dried cells is also dependent on relative humidity. (*c*) Protection appears to rely on the right compound in the right place or on strategically placed —OH groups such as in inositol. (*d*) Protection against all three agents is afforded cells by the same compounds. (*e*) The action of inositol seems to be to replace water and some metabolites. (*f*) The gene or genes controlling certain physiological functions can be protected by the metabolites themselves or inositol. (*g*) The genes for many metabolic pathways appear to be in linear array. (*h*) The replication of DNA requires 'early' protein syntheses. (*i*) The addition of such compounds as chloramphenicol prevents the synthesis of biologically active protein, stops the production of mutants and protects cells against desiccation[12].

If all the experimental facts are considered it would appear that the biologically active code of the DNA molecule is not only the base-pair H-bonds of the Watson and Crick model, but also the display of groups on the 'outside' of the molecule. It is suggested, therefore, that the 'operational' gene for enzyme production is a particular configuration on the outside of the DNA plus a given metabolite, and that in the absence of the metabolite the structural configuration is preserved by hydrogen-bonded water molecules which can be replaced by inositol or like compounds. If this particular DNA configuration is damaged by loss of water on desiccation or irradiation it will obviously affect the inner code when the two halves of the helix separate and deformed daughter DNA will result. The idea is shown schematically in Fig. 3.

A_1 and A_2 are meant to represent the deep and narrow grooves, respectively, on the outside of the intact double-helix DNA molecule. In the various parts of the shallow groove certain configurations exist which allow the attachment of specific small hydrated molecules or water. The exposed configuration of the DNA surface is altered by their attachment and protein formed on this will automatically be coded for the attached substrate. The formation of the protein will result, also, in the production of a specific RNA coded for the enzyme. The attachment of the substrates, proteins and RNA will seriously affect the strength of the base-pair hydrogen-bonds and the two halves of the helix will separate exposing the 'inner' code. Because of the presence of protein (P_1) in the deep groove of the single strand it will attract the necessary complementary bases and form a new double helix with a narrow groove ready for action. Protein (P_1) is, therefore, considered to be a DNA polymerase the internal energy of which is sufficient to 'activate' an existing single strand of DNA and naturally it cannot function unless some DNA is present. The happenings on the other half

Fig. 3. A suggested scheme showing why protein synthesis is necessary for DNA replication

A and *B* represent the two single strands of DNA; *P* represents proteins; *R* represents RNA; *M* represents metabolites

of the original DNA molecule must be somewhat different, and it is suggested that the action of the formed enzyme changes the original substrate and forms a new intermediary compound; this results in the liberation of the coded RNA and the enzyme and the re-orientation of the new metabolite in the same site or its positioning in the next site along the DNA molecule (or more probably along a given chromosome). The latter process will allow a second daughter molecule to form plus new P_1 protein. The process will now repeat itself using the newly formed substrate. Since RNA coded for these various enzymes is being made and shed as the protein functions, it follows that on reaching the cytoplasm it will manufacture more enzyme molecules and protein synthesis as such will go on regardless of what is happening to the DNA. Moreover, if the RNA molecule is a double helix it will duplicate itself in the same fashion as proposed for DNA; the only difference between it and DNA will be that the duplication of the latter takes place in orderly sequence along the chromosomes so that the continuity of the linear arrays, so essential to the life process, is kept intact. There can be no doubt that the RNA carries out of the nucleus parts of these arrays intact, and it can only be assumed that the RNA viruses have reached a stage where their duplication is independent of DNA.

The foregoing hypothesis fits the facts known about gene expression and protein synthesis. It follows that DNA duplication will rely on active protein synthesis, yet once started the latter process can occur without DNA. The necessity of linear array of genes governing the synthesis of a compound, such as an amino-acid, immediately becomes apparent as well as the mechanism by which DNA synthesis takes place in linear fashion on the chromosome. If such assumptions are made, the induction of enzymes becomes the normal method of protein synthesis rather than the abnormal one and our present-day ideas as to what is an adaptive enzyme are largely a matter of the kinetics of the reactions.

Apart from these physiological pointers the stability of a gene towards ultra-violet, X-rays and desiccation in terms of water content, growth medium and phase of growth is readily explained. If metabolites do act in combination with the gene, it follows that in the presence of the metabolite the gene and cell may be more stable, and this is exactly what is found. Presumably the inactive genes are merely hydrated, and hence they are damaged more easily and it can only be assumed that their replication requires the correctly orientated water or attachment of a non-specific molecule such as inositol. This could lead to the production of non-enzymatic histones at biologically inactive sequences of gene sites. These sites, however, would be freed when DNA replication occurred.

If the assembly of amino-acids on the DNA is necessary for its replication, it follows that some cells, as is demonstrated here, may develop multiple blocks in amino-acid syntheses on irradiation, and, hence, only when an external supply of amino-acids is supplied can the DNA replicate and the cells divide. If, as is usual, complementary molecules exist in the cells, some of the progeny will receive DNA in which only the back mutation is apparent. On the other hand, cells grown in minimal medium will possess pre-coded RNA capable of manufacturing the amino-acids and these cells will not require an external supply.

Finally, as is generally accepted, a compound able to bind with the inner code may stimulate the incorporation of an incorrect base. However, irreversible binding of small molecules to the outer codes, or the loss of structural water, could well lead to the distortion of the DNA molecule when it attempts to replicate. Also, compounds able to bind with the outer codes of RNA or DNA should be capable of inducing the synthesis of specific enzymes. In the work recorded here the fact that the cells in minimal medium slurries were so stable would suggest that the metabolites are not removed as a result of enzyme formation.

However, it is well known that DNA synthesis goes on during about 80 per cent of the lifetime of a bacterial cell, so presumably most of the metabolites remain in position. The cell is small, and there is little room to house all the formed enzymes and supplied metabolites; perhaps this is why it has such a short mean generation time. Alternatively, it is possible that the formed enzymatic proteins do not separate from the DNA and, hence, only one of the daughter DNA molecules with the open narrow groove will actually function. In any event, the concept that the 'outer' grooves of the DNA molecule have separate integrities and have definite separate biological functions in the coding of protein and RNA seems to fit not only the present data but also most of the facts known concerning protein syntheses and gene expression. Considered from the point of view of energetics and the shifts in hydrogen-bond strengths that will occur when metabolites are attached or freed from the DNA molecule, the foregoing hypothesis seems not unreasonable and further experimentation designed to test it is being conducted.

I thank Dr. R. Bather of the National Cancer Institute and Dr. T. E. Cunningham of the Department of Pathology for their advice and assistance with the tumour experiments.

This work was supported by grants from the Defence Research Board of Canada and the National Cancer Institute of Canada.

RELEVANCE OF BIOCHEMICAL TAXONOMY TO THE PROBLEM OF LATHYRISM

By DR. E. A. BELL
Department of Biochemistry, King's College, London, W.C.2

VARIOUS species of *Lathyrus* are cultivated throughout the world, and it has been known from earliest times that the seeds of some of these species are toxic when ingested by man and domestic animals, giving rise to a 'disease' known as lathyrism. In man, lathyrism is characterized by a loss of muscular control, paralysis of the legs and in extreme cases death. These symptoms have usually been associated with the ingestion of seeds of *L. sativus*, although seeds of *L. cicera* and *L. clymenum* have also been implicated. Lathyrism is endemic in certain parts of Asia, particularly India, where outbreaks of exceptional severity have been reported during periods of famine when excessive quantities of *Lathyrus* meal have been eaten for want of other food[1,2]. Isolated outbreaks have also been reported from time to time from Europe and the Mediterranean countries.

In seeking the cause of lathyrism some confusion has arisen in the past from conflicting reports as to which experimental animals are affected by the ingestion of *Lathyrus* seeds and from equally conflicting reports as to the symptoms manifested by those which are. I believe that this confusion has resulted from a failure to appreciate sufficiently the important differences which exist between the plant species themselves, and I suggest that the key to the problem lies in the biochemical taxonomy of the genus.

The fact that there are at least two toxic syndromes associated with the ingestion of *Lathyrus* seeds was recognized by Selye[1], who proposed that the term 'neurolathyrism' should be used to describe the classical symptoms caused by those species previously mentioned, and the term 'osteolathyrism' to describe the effects, which include skeletal changes, seen in rats and other animals following the ingestion of *L. odoratus* seeds.

The first toxic compound to be isolated from this genus was the 'osteolathyrogen' obtained from seeds of *L. pusillus* by Dupuy and Lee[3], and from seeds of *L. odoratus* by McKay, Lalich, Schilling and Strong[4]. This compound was later shown to be β-(γ-glutamylamino)propionitrile[5], the toxic portion of the molecule being the β-aminopropionitrile[6]. Some while later, Ressler *et al.* isolated a second toxic compound, showing neurological properties, from seeds of *L. latifolius*. This they identified as α,γ-diaminobutyric acid[7].

When these findings were related to the survey made by me[8] of all the amino-acids and related compounds occurring in relatively high concentration in the seeds of forty-nine species of *Lathyrus*, it was apparent that those species responsible for 'neurolathyrism' in man contained neither β-(γ-glutamylamino) propionitrile nor αγ-diaminobutyric acid. These three species, however, all fell into one of the sub-genera into which *Lathyrus* may be divided on the basis of associations of amino-acids and related compounds in its seeds. The sub-genus concerned was characterized by the presence of high concentrations of two unidentified ninhydrin-reacting compounds. One of these has since been isolated from seeds of *L. cicera*[9] and *L. sativus*[10] and shown to be L-homoarginine. While the possibility that this amino-acid may be toxic to man cannot be completely discounted on evidence obtained from experiments with animals, L-homoarginine does not produce neurological symptoms in chicks[11], which are affected by extracts of the whole seed[12].

The second ninhydrin-reacting compound (designated A_1 by me) is acidic in character and has recently been isolated by Adiga, Rao and Sarma[11], and also independently by Murti, Seshadri and Venkitasubramanian[13]. This compound has been identified as α-amino-β-oxalylaminopropionic acid[14] and, like the seed extracts of *L. sativus*, produces characteristic neurological symptoms when injected into chicks. There can be little doubt that α-amino-β-oxalylaminopropionic acid is the compound responsible for classical 'neurolathyrism' in man.

In my survey it was found, however, that of the twenty species which contain α-amino-β-oxalylaminopropionic acid (A_1), nine (to which a tenth has since been added) also contain two other unidentified acidic ninhydrin-reacting compounds which were designated A_2 and A_3.

T = trace, B_1 = homoarginine, B_2 = α,γ-diaminobutyric acid, B_3 = γ-hydroxyhomoarginine, B_4 = unidentified, N_1 = β-(γ-glutamylamino)propionitrile, N_2 = unidentified, A_1 = α-amino-β-oxalylaminopropionic acid, A_2 = α-amino-γ-oxalylaminobutyric acid (tentative), A_3 = second acidic derivative of α,γ-diaminobutyric acid, A_4 = unidentified, Lat. = lathyrine, Arg. = arginine. Of the five last species listed, three (Nos. 49, 50, 51) contained low concentrations of amino-acids and were not assigned to the previous groups; *L. laetiflorus* contained a neutral compound and *L. venosus* a basic compound not seen in other species. All species contained traces of glutamic acid and aspartic acid.

Using seed of *L. latifolius* the isolation and identification of A_1, A_2 and A_3 were undertaken in this laboratory prior to the isolation of α-amino-β-oxalylaminopropionic acid from seed of *L. sativus*. While this work is not yet complete, it may be of interest to report that in addition to confirming the presence of α-amino-β-oxalylaminopropionic acid in seeds of *L. latifolius*, it has been found that A_2 is an oxalyl derivative of αγ-diaminobutyric acid (the toxic amino-acid previously isolated from the same species). It has been tentatively identified as α-amino-γ-oxalylaminobutyric acid[15], the higher homologue of the 'neurolathyrogen' first isolated from *L. sativus*. Preliminary experiments have also shown that A_3 is yet another acidic derivative of the same amino-acid.

The distribution of these compounds and of other amino-acids found in seeds of *Lathyrus* is summarized in Table 1, from which it will be seen that the seeds of all species in group 1 contain α-amino-β-oxalylaminopropionic acid and their ingestion may be expected to produce symptoms of classical 'neurolathyrism' in man. The seeds of the last three species in group 2 contain αγ-diaminobutyric acid, and their ingestion would induce the neurological symptoms associated with that amino-acid. The seeds of the remaining species of group 2 contain both α-amino-β-oxalylaminopropionic acid and αγ-diaminobutyric acid, the last-named being present both in the free form and combined in two different acidic derivatives. The 'osteolathyrogen', β-(γ-glutamylamino)propionitrile, is found in the seeds of species in group 5 (and also in *L. pusillus*, a species which has not been examined in this laboratory).

When considering methods for the prevention of lathyrism in man, Murti *et al.*[13] suggested that the seeds of *L. sativus* might be rendered non-toxic by boiling in water to remove the α-amino-β-oxalylaminopropionic acid. While such a measure might be used effectively as a temporary expedient it would seem that the permanent eradication of the disease can only be achieved by providing seed and encouraging the cultivation of alternative legumes in the areas concerned. If the choice of alternatives is to be made from species of the same genus, agricultural evaluation may be limited, on the basis of the present account, to species other than those of groups 1, 2 and 5. While some, or all, of the remaining species may yet prove to be toxic, lathyrine (β-(2-aminopyrimidin-4-yl) alanine[16]), which occurs in high concentration in many of them, has been found (like homoarginine, which it accompanies) to be without toxic effects in the mouse and chick[17]. The toxicity of γ-hydroxyhomoarginine[18–20], which also occurs in varying concentrations in certain of these species, has not yet been determined, however, nor have the compounds designated A_4, N_2 and B_4 been isolated in the pure state.

To illustrate the sub-division of the genus and the resolution of most of the compounds discussed, extracts of the seeds of two species from each of the first four groups of Table 1 have been subjected to ionophoresis (5 kV for 15 min) on paper at *p*H 3·6 (Fig. 1). β-(γ-Glutamylamino)propionitrile being uncharged at *p*H 3·6 is not resolved from the neutral amino-acids by this method, but its presence may be readily detected chromatographically on paper using lutidine–water (65 : 35 by vol.) which separates it from the other ninhydrin-reacting compounds found in comparable concentrations in the extracts examined (R_F 31).

It is appreciated that much work on the biosynthesis of these compounds, their phylogenetic significance and in some instances their toxicity remains to be done. Nevertheless, it is hoped that this account may explain some of the unexpected and apparently contradictory results reported in the literature on lathyrism and lead to a clearer understanding of the problems involved.

I thank Prof. H. Harris for his advice and Messrs. W. G. Mackenzie and J. I. H. Rees of the Chelsea Physic Garden and the University of London Botanic Supply Unit for their help in obtaining and growing seed.

CONTINGENT NEGATIVE VARIATION: AN ELECTRIC SIGN OF SENSORI-MOTOR ASSOCIATION AND EXPECTANCY IN THE HUMAN BRAIN

By Dr. W. GREY WALTER, Dr. R. COOPER, V. J. ALDRIDGE, W. C. McCALLUM and A. L. WINTER

Burden Neurological Institute, Stapleton, Bristol

THE amplitude of the electric responses evoked in the human brain by sensory stimulation is usually rather small compared with that of the intrinsic background activity. However, recently developed methods of electronic averaging and cross-correlation[1] have disclosed consistent patterns of response, particularly in the extensive non-specific regions of the frontal lobes[2]. Records from scalp electrodes (which inevitably introduce considerable spatial diffusion) have been compared with those from multiple electrodes implanted in frontal cortex for therapeutic purposes[3]; these latter can be left in position for several months and demonstrate convergent responses to auditory, visual and tactile stimuli in most regions of medial, lateral and orbital frontal cortex. The scalp responses are seen as compounded of these widespread synchronized discharges which, however, involve only a very small proportion of the neural tissue in any one zone.

The non-specific responses (in contrast with those in specific primary sensory areas) showed marked 'habituation' when stimuli in any modality are repeated frequently and monotonously, but their amplitude is restored when stimuli are associated. The rule is that the electro-negative components of the responses to the first (that is conditional or warning) of two stimuli are progressively augmented while those to the second stimuli (considered as unconditional or 'indicative') are progressively attenuated. These effects are generally emphasized and accelerated if the subject is instructed to perform an operant response to the indicative stimuli, which thereby become 'imperative'.

A series of experiments has been performed to investigate the effects on these components of varying the probability of association between the conditional and imperative stimuli, and also the influence of variations in effector participation and mental attitude. The effects of direct suggestion under hypnosis have already been described[4].

The non-specific responses to conditional stimuli usually consist of three main components: a brief surface positive wave, a brief surface negative wave superimposed on this, and a much more prolonged surface negative component which may last several seconds, particularly in children. The details of the first two components depend somewhat on the modality, the responses to auditory stimuli being usually larger, simpler and more consistent than those to visual or tactile stimuli. The features which seem most closely related to the contingency of the situation and to the attitude of the subject are the prolonged secondary negative waves and their interaction with the subsequent responses to imperative stimuli.

Because of its dependence on the statistical relationship between the conditional and imperative stimuli this protracted component of the conditional response is referred to here as the 'contingent negative variation' (CNV). This effect can be recorded accurately only with equipotential non-polarizable electrodes and long time-constants or directly coupled amplifiers. For these experiments, specially prepared and selected silver–silver chloride electrodes were used, connected to an Offner type *TC* 16-channel recorder, fitted with a two-channel automatic wave analyser and a two-channel barrier-grid averager[5]. In order to permit comparison of responses in a variety of situations during a session of reasonable duration with intervals of several seconds between stimuli, the results from sets of only six or twelve presentations were stored and averaged, and the outputs from the averagers were written out directly on the recorder with increased gain and paper speed at the end of each set of presentations, which lasted about 90 sec.

The stimuli, singly or in pairs, were presented automatically at irregular intervals of 3–10 sec. When paired, the interval between associated stimuli was usually one-half or one second, but longer intervals have also been used. The conditional stimuli were either single flashes (*F*) or single clicks (*C*); the indicative or imperative stimuli were repetitive clicks or repetitive flashes. The operant response was provided by a button which the subject was asked to press when the repetitive imperative stimuli were given; this could be connected so that it terminated the imperative stimuli, but the circuit was so arranged that it was ineffective if pressed before the onset of the imperative stimuli.

Observations have also been made during the establishment of involuntary conditioned blink responses to clicks preceding puffs of air to the cornea. Records were obtained from electrodes on several parts of the head, but those illustrated here were all from a vertico-mastoid pair, an upward deflexion indicating negativity of the vertical electrode with respect to the mastoid. Simultaneous records were also obtained of the electro-myogram of the operant muscles, the stimuli, variations in palmar skin resistance, pulse rate and respiration.

The development of the CNV and its interaction with the imperative responses are illustrated in Fig. 1, which is from a normal adult subject. The averages of 12 responses to isolated clicks (Fig. 1*A*) consist of a small positive wave almost obscured by a much larger negative component. The responses to isolated trains of flashes (Fig. 1*B*) show several brief negative components, also superimposed on a small positive deflexion. When the clicks are paired with the flicker about 1 sec later (Fig. 1*C*) both responses are reproduced with little alteration. In these conditions both responses dwindle to noise-level after about 50 presentations. The addition of an operant response by the subject (Fig. 1*D*) is accompanied by a pronounced change in the conditional response to the clicks; a large CNV appears, rising to the peak amplitude of the imperative response during the interval between them. The imperative response itself is now seen merely as a sharp drop in potential difference to the base line. This pattern is maintained indefinitely as long as the subject is attentive and presses the button promptly. It is the same whatever the modalities of the first and second stimuli (Fig. 2*A*). However, when the imperative stimulus is withdrawn, the responses to the unreinforced conditional stimuli show a progressive subsidence of the CNV which disappears almost entirely after 30 unreinforced trials (Fig. 2*A*–*E*). Restoration of the imperative auditory stimulus immediately re-established the CNV (Fig. 2*F*). The dependence of the CNV on the contingency of the association between the two stimuli is shown most clearly when their relation is made equivocal. After a long series of regular associations of flashes with clicks (Fig. 3*A*) the probability of association was 'diluted' by presentation of 27 unreinforced flashes at random between 21 associated pairs, providing only 21 reinforcements out of 48 presentations. Averages taken during this series of equivocal presentations show that the CNV is progressively reduced to about half its previous amplitude, while the imperative response reappears as a negative wave (Fig. 3*B*, *C*, *D*). In most normal adult subjects the CNV shows signs of attenuation when the probability of occurrence of the association drops below 0·7 during 12 or more trials; but the total number of trials, their distribution in time and the critical proportion of reinforcements needed for suppression of the CNV vary considerably from subject to subject. Unequivocal restoration of the conditional stimulus once again brings about a rapid re-establishment of the CNV with submergence of the imperative negative wave (Fig. 3*E*).

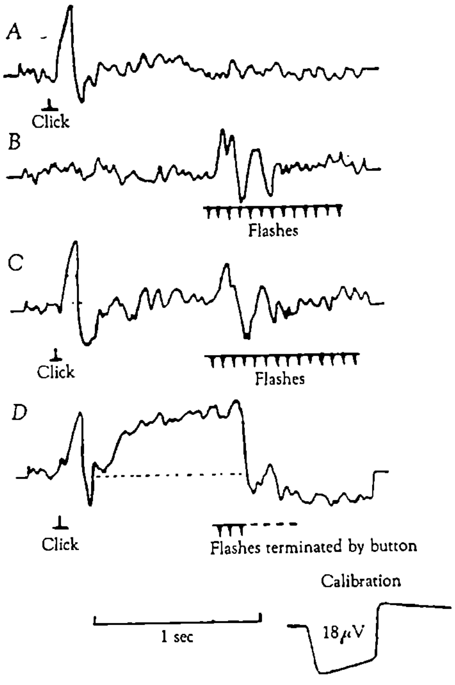

Fig. 1. Averages of responses to 12 presentations. *A*, response in fronto-vertical region to clicks; *B*, flicker; *C*, clicks followed by flicker; *D*, clicks followed by flicker terminated by the subject pressing a button as instructed. The contingent negative variation (CNV) appears following the conditional response and submerges the negative component of the imperative response

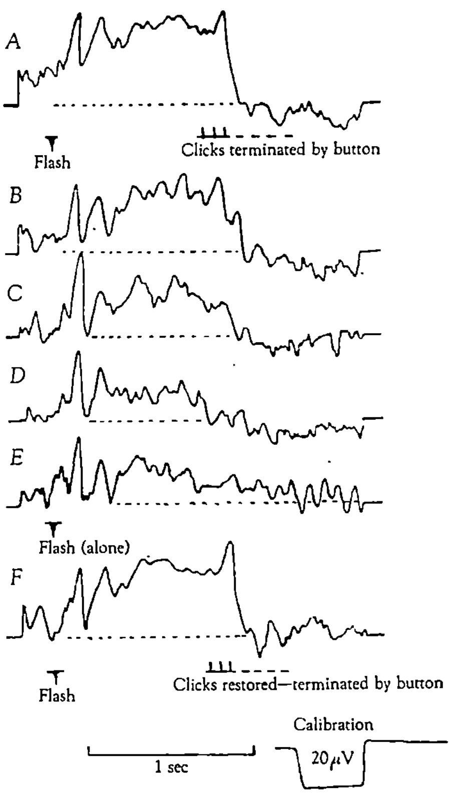

Fig. 2. Averages of 6 presentations. *A*, responses to flicker followed by clicks terminated by subject's operant response. The CNV is fully developed; *B*, average of first six presentations after withdrawal of the imperative stimuli; the CNV is slightly attenuated and there is a 'conditional' negative wave at the phase where the clicks would have been expected; *C*, *D*, *E*: progressive diminution of the CNV as the expectancy of reinforcement subsides. *F*, restoration of the imperative stimulus quickly re-establishes the CNV

Another factor which influences the form of the CNV is the attitude of the subject. During one experiment the subject was told that during a long series of unequivocal presentations of clicks followed by flashes he could decide

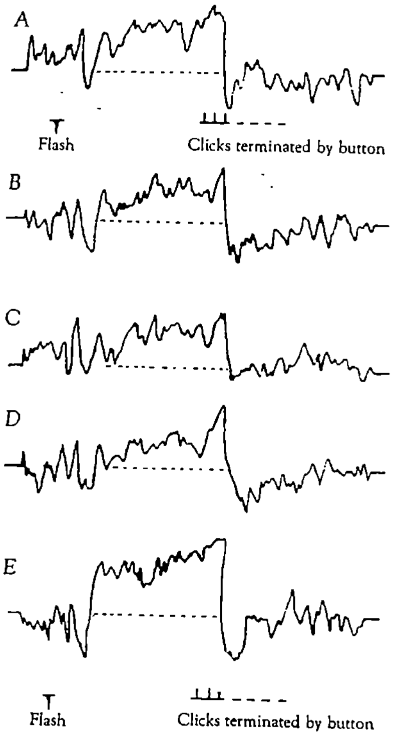

Fig. 3. Averages of six presentations. *A*, responses evoked by regular, repeated association of flashes with clicks terminated by subject; *B*, eight unreinforced flashes interspersed at random between the six associated stimuli reduce the CNV by equivocation; *C*, *D*, continued equivocation progressively attenuates the CNV and the negative component of the imperative response emerges; *E*, unequivocal association again restores the CNV

not to press the button for the operant response. The average of six of these trials showed almost complete absence of a CNV (Fig. 4*A*), but this reappeared immediately when the subject decided to resume the operant response. The CNV is also susceptible to social stimuli in the form of verbal statements. When the imperative stimulus was withdrawn without notice or warning (Fig. 2*B*–*E*) the change in the pattern of physiological stimuli ultimately suppressed the CNV, but only after about 30 trials. In contrast, when the subject was told: 'There will be no more flashes' the CNV disappeared immediately (Fig. 4*B*). In this objective sense, therefore, progressive changes in subjective expectancy produced by repetitive physiological experience can be matched against those established by a single phrase. There may be a qualitative as well as a quantitative difference between the effects of physiological and social suppression. In Fig. 2*B*, the first average after unexpected withdrawal of the visual imperative stimuli, the CNV is slightly smaller than during reinforcement, but there is a small negative wave followed by an abrupt fall in potential difference exactly 1 sec after the conditional stimulus, that is at the instant when the imperative stimuli would have been expected. Bearing in mind that this is the average of six trials and that the second, third and fourth sets of unreinforced trials show steadily diminishing signs of this effect, it may be regarded as a true conditioned brain response induced by the long experience of unequivocal presentations but extinguished as the probability of association declined when the imperative stimuli were withheld. There was no sign of this conditioned response when the subject was told beforehand that there would be no reinforcement (Fig. 4*B*); in fact, with this 'social extinction' there was a slight slow positive variation following the conditional response. Before the next series the subject was told that the flashes would be restored, but this was not done; the first three trials showed an appreciable CNV but the second three showed none, and the average consequently contained only a small CNV (Fig. 4*C*). These features reflected accurately the subjective reports of fluctuations in expectancy induced by the conflict between the verbal and physiological experiences.

When a subject has become accustomed to the presentation of conditional and imperative stimuli separated by 1 or 2 sec the CNV can be sustained even when the imperative stimulus is omitted if he is instructed to estimate the time-interval and perform some action at the moment when the imperative stimulus would have occurred (Fig. 4*D* and *E*). The termination of the CNV is therefore not an 'off-effect'; furthermore, a purely mental judgment of a time-interval, without operant response, is often accompanied by a prominent CNV in trained subjects.

In most adult subjects the development of a consistent CNV with an abrupt termination is associated with a marked reduction in reaction-time to the imperative stimulus. This is not due to the establishment of a time-reflex, as was at first supposed, since the subjects seldom make a single false response when the imperative stimulus is withdrawn, as in the extinction or equivocation trials. Electromyograms of the operant muscles sometimes show a slight change in their tonic balance following the first few unreinforced conditional stimuli, suggesting a persistent anticipatory bias.

The close correlation between attentiveness, expectancy, contingent significance, operant response and the ampli-

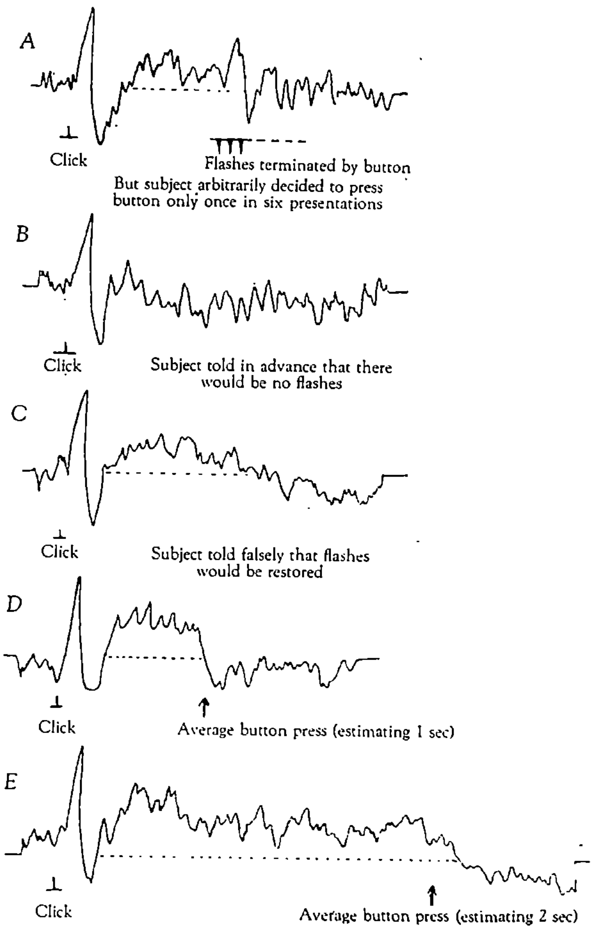

Fig. 4. Averages of six presentations. *A*, the subject decided arbitrarily not to press the button in response to the clicks; the CNV disappears (compare Fig. 1*D*); *B*, when told in advance that the imperative stimuli would be withdrawn the CNV vanishes at once (compare Fig. 2 *B*–*E*); *C*, subject told falsely that flashes would be restored; CNV reappears for first three presentations and then subsides; *D*, without imperative stimulus, subject is asked to press button at estimated one second after click; CNV develops as for associated stimuli; *E*, the same, with subject estimating 2 sec for button press

tude of the CNV suggests that this may be the electric sign of cortical 'priming' whereby responses to associated stimuli are economically accelerated and synchronized. The final discharge, whether in voluntary action or mental decision, is indicated by the abrupt decline in the CNV about 120 msec after the imperative stimuli, corresponding with the positive phase of the non-specific response to isolated stimuli.

The mechanisms underlying this remarkable effect can be inferred from other sources. Caspers[6] has described similar variations in cortical potential in rats during sensory stimulation and arousal which are attributable to depolarization of the apical dendritic feltwork of the cortex. Rowland and Goldstone[7] observed slow shifts of voltage in cats with implanted cortical electrodes during conditioning; they interpret these as "extension of an electrical arousal effect in terms of activation of cortical structures based on relation to drive". Rusinov[8] has also described slow negative waves recorded by Shvets[9], which appeared in the cortex of rabbits with the first appearance of conditioned movements; these were more generalized in the early stages than when the responses were 'concentrated' and vanished during extinction.

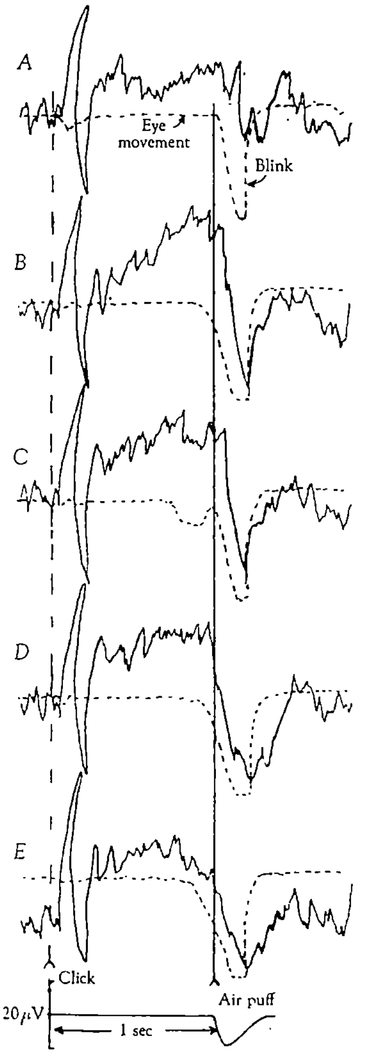

Fig. 5. Averages of 12 presentations; 'classical' conditioning of involuntary blink. Conditional stimulus click, unconditional stimulus air-puff to eye. *A*, first 12 trials show brain responses to both clicks and puffs; blink starts just after puff; *B*, second 12 trials: CNV appears, with conditioned blink just before puff which evokes no brain responses since eyelid is shut before corneal stimulus; *C*, *D*, *E*, progressive decline in CNV as conditioned response is consolidated

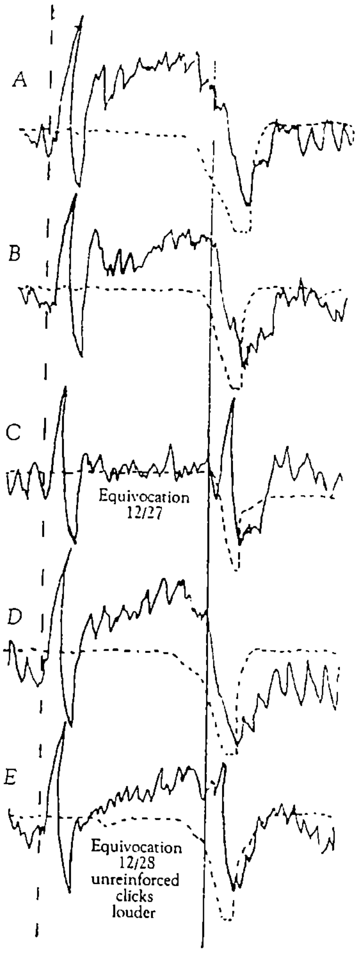

Fig. 6. Averages of 12 presentations of click and puff to eye (same series as Fig. 5). *A*, first 12 presentations after interval; CNV is larger than in Fig. 5*E* but conditional response is still present; *B*, second 12, CNV is smaller; *C*, equivocal association of clicks (only 12 of 27 reinforced) abolishes CNV and conditioned blink; brain response reappears since eye is open to corneal stimulus; *D*, regular association of clicks and puffs restores CNV and conditioned blink; *E*, equivocation as in *C*, but subject detected slight difference in loudness of reinforced and unreinforced clicks

In patients with chronic electrodes implanted over frontal cortex the CNV can be recorded from widely separated areas and remains generalized indefinitely during operant conditioning as in scalp records. During the establishment of a 'classical' defensive reflex, however, the CNV is more prominent in the early stages. This is shown in Fig. 5, taken during the acquisition of a conditioned corneal blink reflex elicited by clicks followed by puffs of air to the eye. In Fig. 5*A* the blink follows the air puff, but in Fig 5*B*, the average of the second dozen presentations, there is a prominent CNV, the blink precedes the air puff and the brain response to the corneal stimulus, which was prominent at first, has disappeared. In subsequent trials (Fig. 5*C*, *D*, *E*) the CNV shrinks progressively, until after about 60 trials it is scarcely above the base-line and the eye is closed well before the air-puff. The effects of 'probability dilution' or equivocation are particularly clear in this situation (Fig. 6). When the significance of the association between the auditory and corneal stimuli is diminished by partial reinforcement both the CNV and the conditioned response vanish entirely and the brain response reappears (Fig. 6*C*). However, when the subject discovered a slight difference between the reinforced and unreinforced conditional stimuli the CNV and conditioned response return, Fig. 6*E*.

Although the electric field of the CNV is generally limited to the anterior regions, there is some indication that variations in its spatial extent may be related to the degree and pattern of contingent response interaction, particularly in children. The application of these methods to the investigation of neuropsychiatric disorders has already shown a surprisingly close correspondence between the objective signs of cerebral expectancy and the mental state of disturbed patients.

This work was supported in part by the Mental Health Research Fund and the Parapsychology Foundation of New York.

RECEPTORS IN THE SUCKER OF THE CUTTLEFISH

By PROF. P. GRAZIADEI

Department of Anatomy, University College, London

CERTAIN proprioceptors of crustaceans have proved to be useful in experimental investigations because both the cell body and dendrites lie at the periphery[1,2]. This situation has been found in the mantle of cephalopods[3,4]. The work recorded here shows that such multipolar nerve cells with the characteristics of receptors are also found in the suckers of the cuttlefish.

The general arrangement of the tentacular arm of *Sepia officinalis* has been described by Guérin[5] and my previous papers[6–8]. The sucker is cup-like, joined to the arm by means of a short peduncle (Figs. 1 and 2). The cup contains three principal zones where primary receptors can be demonstrated. These are: (1) the external side of the infundibulum (*A*, Fig. 1); (2) the flat rim of the cup (*B*, Fig. 1); (3) the bottom of the acetabulum (*C*, Fig. 1). These three zones contain several sorts of sensory cells, differing in shape and presumably in their capacity of recording information. Zone *A* is covered with columnar epithelium 30–40μ thick (all the numerical data given in this paper are related to suckers of approximately 3 mm diameter, from adult animals, 10 cm mantle-length). There are two types of receptors, probably touch- and chemo-receptors, in zone *A*. The touch-receptors have round or flask-like cell bodies lying in the inferior third of the epithelial layer and their axons go to one of the twelve nerve bundles that radiate from the peduncle into the wall of the sucker (Figs. 1 and 2). From the intra-epithelial course of the axon may arise some fine collaterals branching between the epithelial cells and intermingling with each other in a fine plexus at the base of the epithelial layer. The other type of cell is probably a chemo-receptor, because similar cells have been found in the lip of *Sepia officinalis*[9]. These cells are tapered and end at the free surface of the epithelium with a tuft of short cilia (2–3μ long). It is very difficult to state the number of these receptors because they stain only sporadically with the methods used (Bielschowsky, Cajal), but an approximate estimate is not less (probably much more) than 600 and 100 for touch- and chemo-receptors respectively in each sucker.

The flat rim of the sucker (zone *B*) is covered by a single layer of epithelium, unusual in that each cell is covered by a tooth-like cuticular apparatus (Fig. 3). The size of the epithelial cells is 30–40μ long and the cuticle is not less than 40–50μ thick. The cuticle provides a ring-shaped surface by means of which the sucker holds the objects grasped. There are multipolar nerve cells between the epithelial cells (approximately 300 in each sucker) which send branching processes ('dendrites') to the base of the stratum (Figs. 4, 5 and 6). These cells are presumably tension receptors. The size of these irregular nerve cells varies from 20 to 60μ (the size is taken as the average of the two largest diameters of the cell) and the processes of each cell spread over an area of 100μ diameter, each dendritic field overlapping the neighbouring ones. The axon arises from the hillock of the cell but light microscopy shows no changes in structure (Nissl and Cajal methods). The diameter of the axon remains considerable (8–12μ) along its entire course, and it may run without collaterals for more than 50μ in the epithelium (Fig. 4), where it turns into the muscular wall of the sucker (Figs. 1 and 6). Here it intermingles with the fibres forming the nerves of the sucker running to and from the arm ganglion. In this epithelium some very fine fibres of unknown nature (probably coming from the sucker ganglion) branch and intermingle with the dendritic processes of the nerve cells previously described.

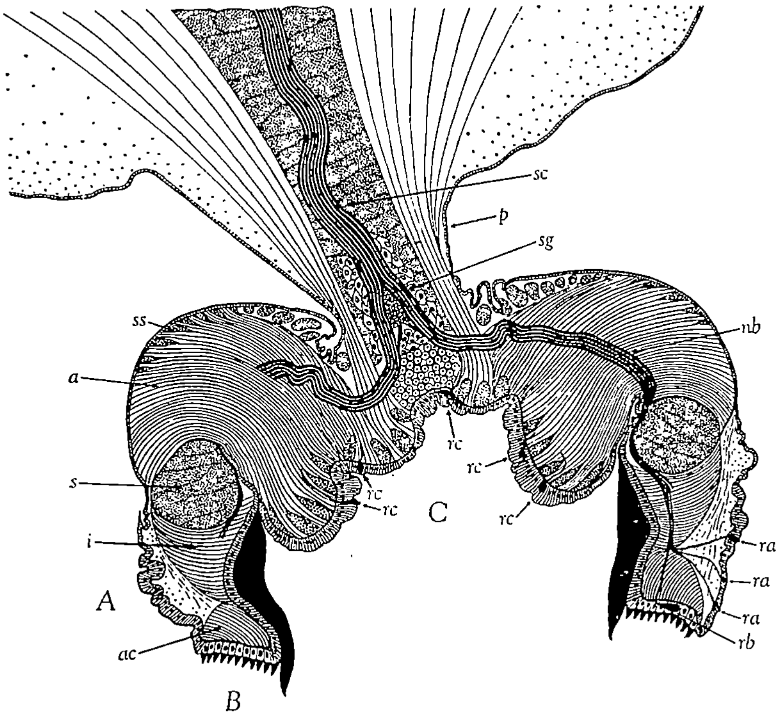

Fig. 1. Diagram of a sucker of *Sepia officinalis*, showing the general arrangement of the organ and its nerve supplies. *A*, *B*, *C*, zones of the sucker provided with different types of receptors. *a*, acetabular muscle; *ac*, acetabulo-cutaneous muscle; *i*, infundibular muscle; *nb*, nerve bundles radiating from the ganglion into the sucker: *p*, peduncle of the sucker; *ra*, receptors of the zone *A*; *rb*, receptors of the zone *B*; *rc*, receptors of the zone *C*; *s*, principal sphincter of the sucker; *sc*, sucker's nerve; *sg*, sucker ganglion; *ss*, secondary sphincters of the acetabulum

Automatic methods in volumetric analysis

D. C. M. SQUIRRELL

To be published in September, and emphasizing methods while paying due attention to instruments, this book illustrates the types of volumetric analysis in which automation has advantages. It gives its methods in enough detail for readers to be able to evaluate them for particular applications. Dr J. Haslam has contributed a preface.

COMPLEMENTED MODULAR LATTICES AND REGULAR RINGS

L. A. SKORNYAKOV

The determination of connections between diverse phenomena is one of the fundamental tasks of every science. It is, therefore, of special interest when a link is discovered between mathematical objects which at first sight seem completely heterogeneous. One such link, between complemented modular lattices and regular rings, has been revealed on the borderline between algebra, geometry and functional analysis.

This book gives a self-contained survey of the widely ramified theory of complemented modular lattices and of continuous geometry, together with other applications. The whole field is covered and proofs are set out in detail. Many interesting results that do not fit into the main line of exposition are also stated with the aim of stimulating further research on the subject.

THE JOURNAL OF HORTICULTURAL RESEARCH

Within the general context of horticulture, this Journal publishes research papers and reviews in the fields of experimental agronomy, soil science, plant physiology, plant breeding, plant pathology and related subjects. Reports on such subjects as performance trials of plant varieties and stock are also included.

Other features include a section of short notes and reviews of books.

Published twice yearly in MAY and NOVEMBER.

Advances in Photochemistry
Volume I

edited by W. A. NOYES, JR., *Department of Chemistry, University of Rochester*
G. S. HAMMOND, *Department of Organic Chemistry, California Institute of Technology*
and J. N. PITTS, JR., *Division of Physical Science, University of California, Riverside*

Through new methods of analysis the photochemist is permitted to approach the truly fundamental problem of photochemistry. What is the detailed history of a molecule which absorbs radiation ? In this new series of books entitled ADVANCES IN PHOTOCHEMISTRY, the chapters are written by pioneers who are experts. The purpose of the series is to stimulate photochemistry research and to bring together the varying viewpoints of many photochemists.

444 pages. 125s.

Lectures on Modern Mathematics
Volume I

edited by T. L. SAATY, *Mathematics Branch Office of Naval Research*

These expository lectures have their origin in an 18 lecture series given at George Washington University and jointly sponsored by the University and the Office of Naval Research, which will be published in three volumes. The intention of the series of lectures was to invite each of the eminent men represented to delineate a substantial research area, to describe it broadly and comprehensively for an audience of mathematicians who are not specialists in that area, and to contribute to this description his individual evaluation of the aesthetic and practical aspects of the field, its position in mathematical development as a whole, and its future, as that might be implied in the conjectural exposition of its unsolved problems.

192 pages, 45s.

Progress in Physical Organic Chemistry
Volume I

edited by S. G. COHEN, *Department of Chemistry, Brandeis University*
A. STREITWIESER, JR., *Department of Chemistry, University of California, Berkeley*
and R. W. TAFT, JR., *Department of Chemistry, Pennsylvania State University*

Physical organic chemistry concerns the application of the basic theories and methods of physical chemistry to the broad areas of knowledge and organic reactions and organic structural theory. This new series will provide a forum for critical and authoritative reviews in which the author is encouraged to present his personal ideas.

424 pages, 115s.

Advances in Analytical Chemistry and Instrumentation
Volume 2

edited by C. N. REILLEY, *Department of Chemistry, University of North Carolina*

This venture in the field of analytical chemistry presents a continuing series of volumes dealing with significant new ideas and techniques, as well as the status of important, but more classical, methods. Written by outstanding workers, the chapters of each volume will offer both description and critical evaluation of a variety of current developments.

408 pages, 115s.

Semiconductor Fundamentals: Devices and Circuits

A. H. SEIDMAN, *Assistant Professor, Electrical Engineering Department, Pratt Institute*
and S. L. MARSHALL, *Editor, Semiconductor Products Magazine*

The purpose of this book is to provide an understanding of the operation of diodes and transistors, their technology, and their application in circuits. Engineers, other than electrical engineers, seeking acquaintance with semiconductors will find here a useful introduction to the subject, and the book will offer a firm background of fundamentals to technicians and others engaged in the field of electronics. It also provides numerous illustrative examples to aid in the understanding of the theory and applications.

287 pages, 50s.

The Adiabatic Motion of Charged Particles

Theodore G. Northrop, *University of California, Lawrence Radiation Laboratory, Berkeley*

Number 21 in the series Interscience Tracts on Physics and Astronomy. It contains a deductive and complete treatment of the approximate (i.e., adiabatic) theory of charged particle motion in a slowly varying electromagnetic field. The trajectory of such a particle can be obtained more exactly by numerical integration of the non-linear equation of motion. However, the approximate theory is adequate for many purposes. It is particularly useful in space physics, where the time and space scale of events is very large. It is also the basis of much theory used in plasma physics and the controlled thermonuclear work.

109 pages, 45s.

Lectures in Theoretical Physics

Volume V

edited by W. E. Brittin, B. W. Downs and J. Downs, *Department of Physics, University of Colorado*

This new volume of "Boulder-Lectures" maintains the high standard of the well-known series.

Contents: Behaviour of De Broglie Wave and Wave Packets; Recent Developments in Scattering Matrix Theory of Particles and Resonances; Theories of Ferroelectricity in KH_2PO_4; Topics in Quantum Electronics; Group Theoretical Approaches to Nuclear Spectroscopy; Dynamics of Electrons in Crystals; Theory and Practice of the Fermi Surface of Metals; The Universe in the Light of General Relativity; Mach's Principle as Boundary Condition for Einstein's Field Equations.

585 pages, 90s.

Crystal Structures

2nd Edition, Volume I

Ralph W. G. Wyckoff, *Professor of Physics and Bacteriology, University of Arizona*

This is the first volume in a five volume series describing and illustrating all known crystal structures. Previously published in loose-leaf format, it is the only complete and up-to-date comparative description available of existing crystal structures. An ample bibliography and a clear statement of atomic positions are included, and the visualization of structures is achieved by extensive illustration, showing the way atoms "pack" together in forming crystals. Each chapter is provided with master tables which list the crystals described and give the paragraph references.

480 pages, 132s.

Fast Neutron Physics, Part II Experiments and Theory

edited by J. B. Marion, *University of Maryland* and J. L. Fowler, *Oak Ridge National Laboratory* (*Interscience Monographs and Texts in Physics and Astronomy, edited by R. E. Marshak, Volume 4*)

The first part of this two volume work was concerned with experimental techniques: Part II gives the results obtained from experiments involving fast neutrons and describes the theoretical basis for the interpretation of these results. There is an extensive system of referencing, not only to original literature, but also to compilation in this field of neutron physics, which leads the reactor engineer or nuclear scientist to the source of neutron cross section literature which has been compiled, in part. from the experiments described in this book.

1,284 pages, 340s.

Part I: 1960. 1,007 pages, 265s.

Organic Electronic Spectral Data

Volume IV—1958-1959

edited by J. P. Phillips and F. C. Nachod

This volume is a compendium of ultraviolet and visible spectra, abstracted by more than fifty contributors from the 1958 and 1959 issues of over 80 chemical and allied periodicals. Volume I (1946–52 *edited by M. J. Kamlet*) and Vol. II (1953–55, *edited by H. E. Ungnade*) were published in 1960. Vol. III is in preparation. These volumes will represent an unique collection of organic electronic spectral data and form a convenient, comprehensive catalogue.

Vol I: 188s.
Vol. II: 113s.

1,192 pages, 150s.

Polymer Single Crystals

Phillip H. Geil, *Research Triangle Institute, Durham, North Carolina*

Volume 5 in the series *POLYMER REVIEWS*, *edited by H. F. Mark*. This book covers for the first time in detail the morphology of crystalline polymers. The application of electron microscopy to crystalline polymers has shown that a vast amount of detailed morphological information is susceptible to study and description. The data that have been reported for crystals grown from both solution and melt are considered. In addition the author discusses the initial steps that have been taken towards the description of polymers on a molecular scale, through the joint application of microscopy and a number of other techniques.

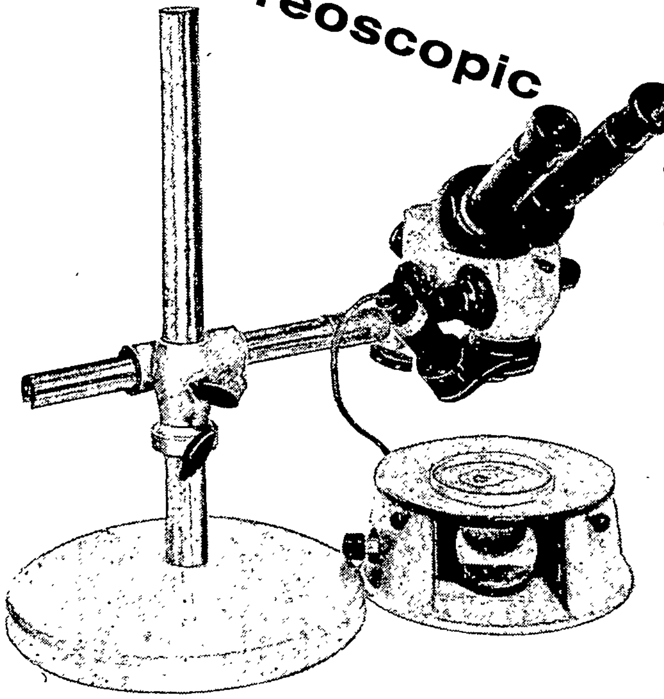
Stereoscopic Microscopy



- Constant working distance allowing adequate room for manipulation and dissection.
- Instant magnification changes by turning indexed drum.
- Uses transmitted or reflected light.
- Magnification range 3.6 × to 88 ×.
- Field of view from 42 mm to 2.6 mm.
- Measuring eyepiece and graticules.
- Universal stand has 8 in. rack and pinion horizontal movement.

Price £134 complete.
(or £125 without stand) 7 days delivery.

Our Advisory Department will gladly answer your enquiries with regard to the suitability of this equipment for your specific uses. Furthermore, these instruments are available to you for 14 days without obligation in order that their versatility may be determined under your actual working conditions.

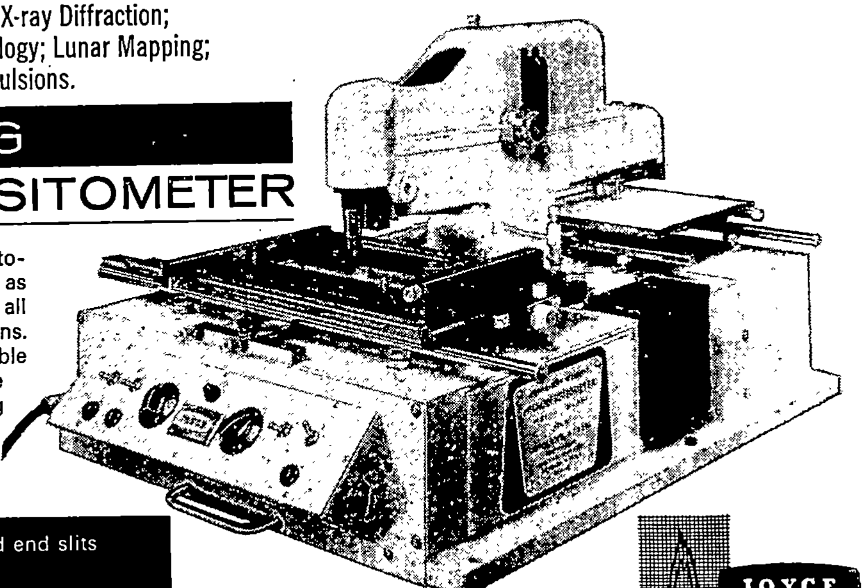
RECORDING
MICRODENSITOMETER

The Joyce, Loebl Microdensitometer has become established as a standard instrument in all types of basic research situations. The instrument employs a double beam self-balancing wedge system giving direct recording of density and will resolve down to a few microns.



- Infinitely variable primary and end slits (variable in both directions).
- Rapid interchange of wedges of different anges and also of different laws.
- Plate advance proportional to rate of rise of density at the end slit.
- Coupled sample and record tables, driven by a single motor. Ratios 1--1,000 : 1 or more.
- Automatic Integrator optional.

MICROMANIPULATORS

if you use a
MICROSCOPE
you need a
SINGER
FULLY PATENTED
MICROMANIPULATOR

Singer micromanipulators are used in most laboratories all over the world. Three types available:

Mk I Low power for magnifications ×1 to ×200

Mk II For magnifications ×1 to ×500

Mk III High power for magnifications ×100 to ×1,000 *plus*

The most advanced instruments for micromanipulation. As described by Barer and Saunders-Singer with further improvements.

Full details and demonstrations upon request to :

SINGER INSTRUMENT CO. LTD.,
Fountain Court, 83 London St.,
Reading, Berkshire, England.
Telephone: Reading 53613.

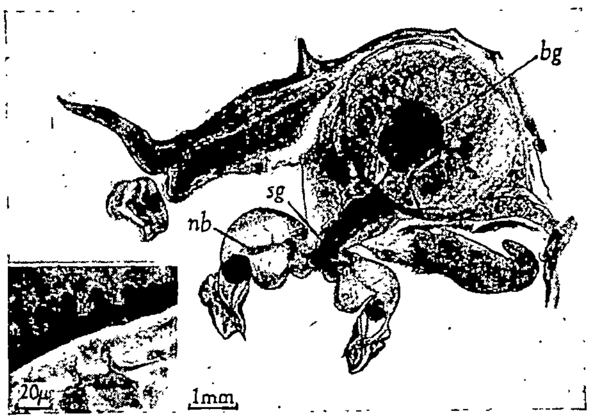

Fig. 3 Fig. 2

Fig. 2. Transverse section of an arm of *Sepia officinalis*, showing two suckers (Bielschowsky–Gros). The brachial ganglion (*bg*) and the sucker ganglion (*sg*) are joined by means of a nerve trunk, the nerve of the sucker. Nerve bundles (*nb*) radiating from the peduncle into the sucker carry sensory as well as motor fibres

Fig. 3. Epithelium of the zone *B*, with its tooth-like cuticular apparatus. Method: hæmatoxylin–eosin

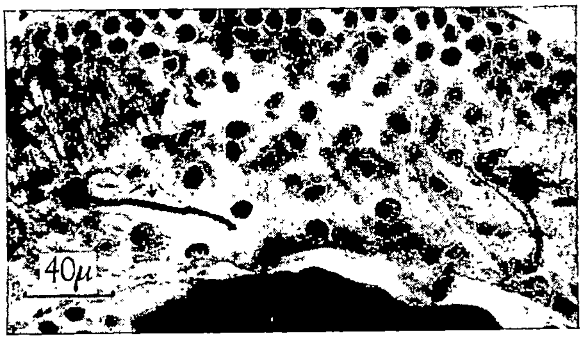

Fig. 4. Tangential section of the epithelium of zone *B*, with two multipolar nerve cells. The arrow shows the axon (Cajal–Young)

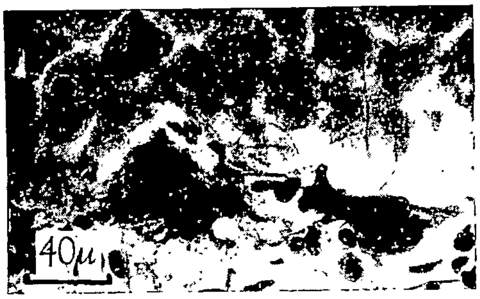

Fig. 5. Same epithelium as in Fig. 4, with two multipolar nerve cells (Cajal–Young)

The bottom of the sucker (zone *C*, Fig. 1) also contains primary receptors, of the three types already mentioned. Two of these closely resemble those previously described in zone *A*. There are very few, perhaps not more than 50, tapered sensory cells with a tuft of cilia, and there are about 200 flask-shaped cells at the base of the epithelium. The third category of receptors consists of a small number of multipolar nerve cells (Fig. 7), perhaps not more than 20, found only in a limited area of the epithelium above the ganglion that lies in the peduncle. These cells are triangular or polygonal in shape. Three or four dendritic processes leave the cell body. Each has a large base and maintains a large diameter (10μ or more) between the epithelial cells, in spite of giving off frequent collaterals. The dendrites of each cell form a dense arborization at the base of the epithelium, each one covering an area 100–200μ in diameter and intermingling with the neighbouring ones. There are, however, some differences between these cells and those previously described of zone *B* (Figs. 4 and 5). The cell body of zone *B* (Figs. 4 and 5) is large, with an irregular mass of cytoplasm round the nucleus and the processes arise from short, irregular laminar expansions of the cell body, forming a complex hair-like ramification round the cell. In zone *C* the cells have a small, pyramidal body, with little cytoplasm, and the dendrites arising are few and large (Fig. 7). The common feature of these two types of receptors is that their dendrites expand only in one plane, parallel to the epithelial surface and near the basal membrane so that some tangential sections show the entire complexity of every cell covering with its processes an area of 100μ, or more, diameter.

In the peduncle of the sucker (Figs. 1 and 8) there is a small, pear-shaped ganglion containing about 200 nerve cells. The larger cells (30–50μ) are motor ones sending axons to the muscles of the sucker. The ganglion is in the path of the bundles running from the arm ganglion to the sucker (Fig. 2) and these bundles carry approximately 1,000 fibres of various types (motor, sensory and interconnecting fibres).

The three types of receptors presumably send inputs of different kinds from the sucker of *Sepia* to the arm ganglia. The tapered ciliated cells may be chemo-receptors as comparative observations with light- and electron-microscope seem to confirm[10], and the flask-shaped receptors are perhaps touch-receptors. The multipolar nerve cells found in zones *B* and *C* seem to belong to a particular category of sensory elements which can now be called 'tension receptors'. In fact, these cells lie under a deep stratum of cuticle (Figs. 3 and 6) or at the bottom of the sucker, where tactile stimuli can scarcely be recorded (if at

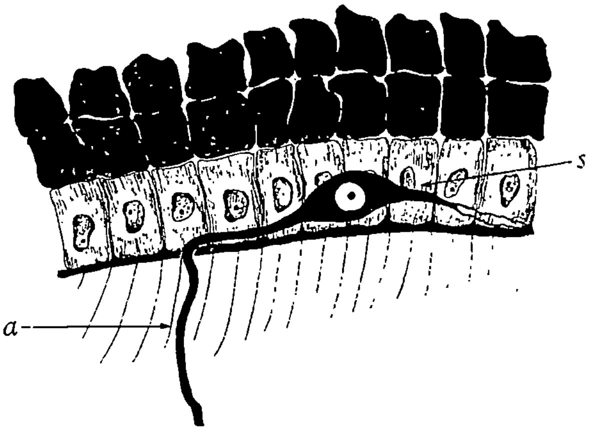

Fig. 6. Schematic diagram of the epithelium of the zone *B*, covered by a deep stratum of cuticle (in black). The sensory cell (*s*) lies between the epithelial cells, above the basal membrane, to which it sends fine, hair-like dendritic processes. (*a*) Axon of the sensory cell

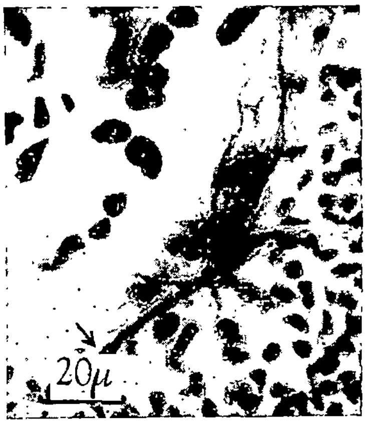

Fig. 7. Multipolar nerve cell of the zone *C*. The arrow shows the axon (Cajal–Young)

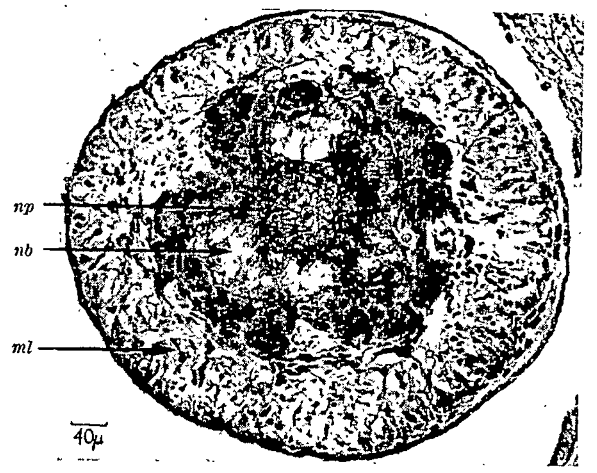

Fig. 8. Transverse section of the peduncle of the sucker (Cajal–Young). The ganglion of the sucker is surrounded by the peduncular muscles (*ml*). A fine network of nerve fibres in the core of the ganglion constitutes the neuropil (*np*). Between the neuropil and the nerve cell bodies lie bundles of fibres (*nb*) connecting the sucker to the arm ganglion (see also Figs. 1 and 2)

all). The extension of the dendritic field and the close relationship of the dendrites with the epithelial basal membrane suggest a comparison with the stretch-receptors previously described in the muscles of these animals by some authors[3,11]. When the animal grasps an irregular object or prey, the rim of the sucker bends and the deformation of the cup cannot be detected by the other receptors. There seem to be no muscle stretch-receptors in these organs and the third type may be the morphological structure underlying the recording of stretch events.

I thank Prof. J. Z. Young for his helpful advice. Mr. A. J. Aldrich took the photographs and drew Fig. 6, and Mrs. J. I. Astafiev drew Fig. 1.

COOLING TIME OF SILICA FIBRES

R. G. C. ARRIDGE and KATHLEEN PRIOR
Rolls-Royce, Ltd., Advanced Research Department, Old Hall, Littleover, Derby

IN many discussions of the strength of glassy materials reference is made to the rapid cooling rate achieved when fibres are drawn from a melt. This rate is held to be so high that relaxation processes in the glass do not have time to occur and therefore the filamentary glass retains the structure belonging to a higher temperature.

During the exploratory stage before the development of a silica fibre drawing-coating process, we decided to measure the temperature of a silica fibre by a direct method since the fibres appeared to be much hotter than expected on Anderson's theory[1].

The method used was an adaptation to high temperatures of the Culpin and Madoc Jones[2] heated thermocouple method. The thermocouple was welded to a thin strip of nickel–chromium alloy resistance element bent into a V shape. The temperature attained by the strip on heating electrically was recorded by the thermocouple potentiometer. When this device was dabbed momentarily on to the running silica thread a kick of the potentiometer needle was obtained in one direction or another accordingly as the thread conveyed heat to, or away from, the thermocouple. When a position on the thread was found where the temperature corresponded to that of the thermocouple no kick in either direction was registered.

Surface temperatures of threads could therefore be measured either by selecting a particular temperature and moving up or down the thread until no deflexion was registered on dabbing, or by selecting one place and adjusting the thermocouple temperature to give no deflexion. Both methods gave the same result to within experimental error.

The thermocouple device was calibrated by inserting it into a uniform temperature enclosure.

The effect of frictional heating was shown to be negligible by tests on cold running threads.

Fig. 1 shows the cooling curves for fibres of various diameters (28–68μ) drawn from 4-mm rod at speeds of 178–508 cm/sec. For comparison, the calculated (Anderson) cooling curve for a 48μ fibre drawn at 178 cm/sec is shown in the same diagram.

Fig. 2 shows the cooling curve for the 48μ fibre replotted on a log temperature–time basis which should yield a straight line if Newton's law of cooling were followed. The curve shows a turning point at about 150° C, the departure from Newton's law becoming excessive below this temperature.

Comparison of the measured times with Anderson's predicted values shows that the measured value is about 30 times greater than that predicted in the logarithmic cooling region and becomes even greater below the critical temperature, 150° C.

On Fig. 3 we have plotted the measured times for cooling to 200° C against the fibre radius on a log–log plot.

The fit is reasonably linear for all speeds and gives a slope of 1·8.

Thus the time for cooling to 200° C is proportional to $(\text{radius})^{1\cdot8}$ as against Anderson's predicted figure $(\text{radius})^{2\cdot5}$. There are too few results really to comment, but it would

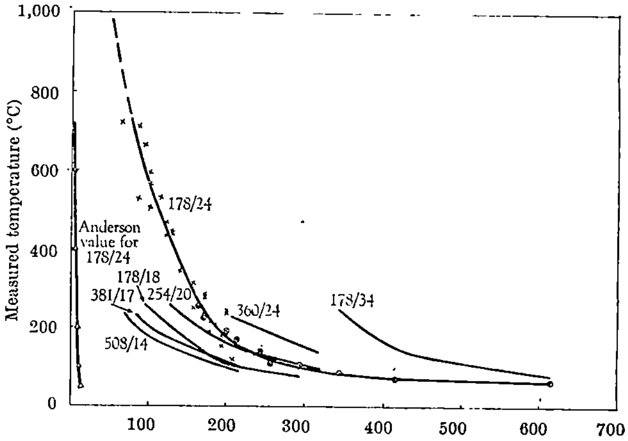

Fig. 1. Comparison of theoretical (Anderson) and experimental cooling rates for silica fibres drawn from 4-mm rod at 1750° C at various speeds

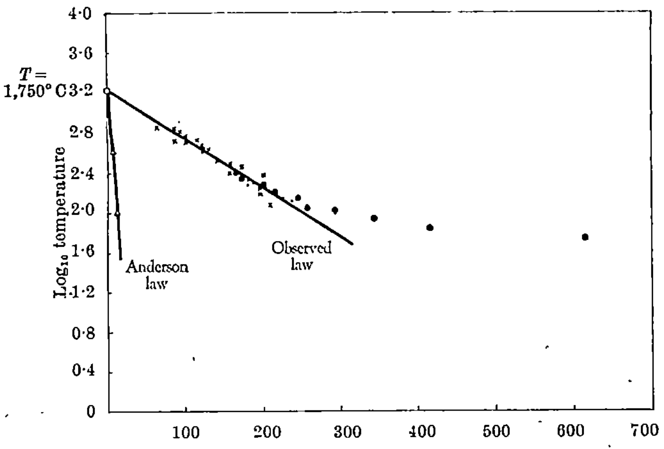

Fig. 2. Log temp.-time plot

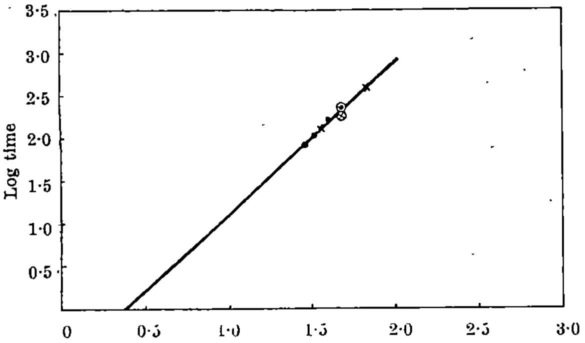

Fig. 3. ●, Constant Q; ×, constant V; ○, constant R

appear that Anderson's law of radius dependence is not followed.

In the (one) case of a change of speed where the radius is kept constant the faster thread, in fact, cools more slowly than the slower, whereas Anderson's theory predicts a $v^{-\frac{1}{2}}$ relation.

Anderson's theory predicts a relation:

$$t = \frac{B\,R^{2-n}}{v^n}\ln(1/y)$$

$B \sim 400$ for silica (using a value 0·007 for the thermal diffusivity)

$n = \frac{1}{2}$

$y = (T - T_0)/(T_i - T_0)$

R is the radius of the thread, v the velocity.

We assume $T_i = 1{,}750°$ C, $T_0 = 20°$ C.

Using this relation we have calculated the cooling times predicted by the Anderson theory for our fibres. for comparison with the observed values.

Table 1

Process (speed/radius)	Time to cool to 400° C (msec)		Time to cool to 200° C (msec)		Time to cool to 100° C (msec)	
	Theor.	Obs.	Theor.	Obs.	Theor.	Obs.
508/14			2·1	85	2·9	200
381/17			3·1	100	4·2	220
254/20			5·1	165	6·9	310
178/24	5·4	130	8·0	190	10·8	300
178/34			13·5	375	18·3	540
178/18			5·2	130	7·0	220
360/24			5·6	240	7·6	—

We offer no explanation of the large time difference between Anderson's predicted and our measured values, but a possible explanation of the departure from Newton's law of cooling below about 150° C is as follows.

When a silica fibre is being drawn it is nearly invisible, yet on touching it a bright spot of light is seen where the internally reflected radiation from the hot molten zone can emerge at the point of damage.

The magnitude of the radiative heat transferred assuming a black body radiator of area equal to that of the fibre is 5×10^{-4} cal/sec. On Newton's law of cooling, the heat lost per second by the fibre at, say, 100° C is of the order of $1{\cdot}37 \times 10^{-2}$ cal/sec. Allowing for the possibility that a larger area may be involved in radiation at the point of draw than the area of the fibre cross-section (for example, during draw down) then the radiative term may affect a measuring instrument more than the Newton term and, being of constant value, contribute increasingly at the lower temperatures.

The fact that the times of cooling are considerably longer than are predicted on the Anderson theory calls into question some of the ideas about structure which require rapid cooling times. Either these ideas are erroneous (for example, the frozen-in high temperature structure) or the relaxation time in silica is several orders of magnitude longer than it was thought to be.

ELECTRON MICROSCOPE OBSERVATION OF NUCLEAR REACTIONS

By Dr. LEWIS T. CHADDERTON and IAN McC. TORRENS

Laboratory for the Physics and Chemistry of Solids, Cavendish Laboratory, Cambridge

It has been shown that it is possible to observe by electron microscopy the tracks formed in various crystals due to the passage of heavy charged particles such as fission fragments[1–3], and that the appearance of these tracks is sensitive to the energy and mass of the bombarding particle and to the thickness of the crystal[4]. In an attempt to observe directly the damage caused by lightly ionizing particles, thin crystals of molybdenum trioxide were irradiated with helium-3 ions of energy 29 MeV.

Molybdenum trioxide was prepared by condensation from the vapour directly on to a carbon support film on an electron microscope grid: grown by this method the crystals ranged in thickness from less than 50 Å to several thousand Å. The grids were mounted on brass backing plates and bombarded for varying periods of time with 29-MeV helium-3 particles accelerated by the Nuffield cyclotron of the University of Birmingham, the total doses ranging from 10^{10} to 10^{16} ions/cm^2. The irradiated crystals were investigated using the A.E.I. *E.M.*6 electron microscope operating at 75 keV.

Observation of crystals bombarded by 10^{15}–10^{16} ions/cm^2 revealed a number of particle tracks, which were occasionally darker than the surrounding crystal due to the operation of diffraction contrast but were more often light tracks due to the removal of material of the crystal (Fig. 1). The track thickness was generally considerably less than that of fission-fragment tracks, varying from ~ 25 Å to ~ 100 Å. A comparison with an electron micrograph of fission-fragment tracks in MoO_3 is given in Fig. 2. The density of the tracks, which was estimated to be $\sim 10^6$/cm^2 in a grid bombarded by 10^{16} helium-3

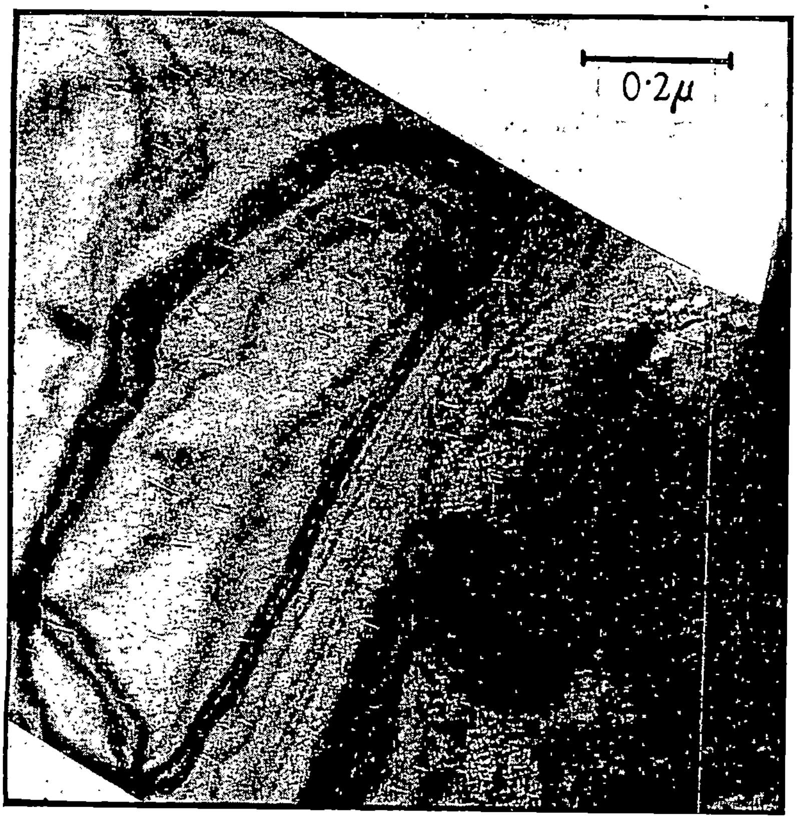

Fig. 1. Tracks in a ³He-irradiated crystal of MoO_3. Often, as in this micrograph, they appear to come from a thick crystal. It is suggested that they are formed by nuclei recoiling from nuclear reactions in the thick crystal

ions/cm², was extremely low in comparison with the beam intensity. It varied considerably over any one grid square, in that the tracks tended to occur in clusters where the density was up to a thousand times the average density, and there were large areas containing no visible tracks. Similarly, the directional variation of the tracks was quite uniform when averaged over a complete grid, but they were usually well collimated (to within 20°) in any one crystal or group of crystals, though not in any particular crystallographic direction. In this respect it is significant that they were not visible in all crystals, and were more often observed where a thin crystal was close to a cluster of thick crystals, aligned approximately in the direction of the cluster.

Mechanism responsible for track formation. The evidence presented here suggests that what we are observing is some form of secondary effect caused by the interaction of the incident helium-3 ions with the atoms of the crystal or with the copper of the electron microscope grid. The bombardment was performed with the plane of the grid perpendicular to the ion beam, and so the tracks in thin crystals must make an angle of ~ 90° with the incident particles. Consideration of the types of secondary effects possible shows that they must be created by one or more of the following effects: (1) the helium-3 particles themselves, having undergone large angle collisions; (2) primary knock-ons due to small impact parameter collisions of the incident ions with the molybdenum or oxygen atoms of the crystals, or with copper atoms of the grid; (3) ions resulting from nuclear transmutations initiated by the helium-3 particles in the nuclei of the crystals or grid.

It is unlikely that the tracks are formed directly by the incident ions after being scattered through approximately 90°. The rate of loss of energy by ionization and excitation of a heavy energetic charged particle passing through matter can be calculated using equations derived by Bohr[5] and by Bethe and Bloch[6]. The Bohr equation applies to a particle the effective charge of which decreases as it slows down in the medium, and is therefore mainly used in calculations involving very energetic heavy ions. The Bethe–Bloch equation can be stated:

$$-\frac{dE}{dx}=\frac{4\pi N Z_1^{*2} e^4}{m_e v^2} Z_2 \log_e\left(\frac{2 m_e v^2}{K Z_2}\right)$$

where v is the velocity of the charged particle, m_e and e the electronic mass and charge, N the atomic density of the matter (No. of atoms/c.c.), K is a constant of the order of 11·5 eV, Z_1 and Z_2 the atomic numbers of the particle and material through which it is travelling, and Z_1^* is the effective charge of the energetic particle, which depends on its degree of ionization. By considering Z_2 as a weighted average of the atomic numbers of molybdenum and oxygen, the energy loss rate for a helium-3 ion travelling in MoO_3 can be calculated by the Bethe–Bloch equation to be:

$$\left(-\frac{dE}{dx}\right)_{^3\mathrm{He}} = 0{\cdot}00247 \text{ erg/cm}$$

This can be compared with the energy loss for a median-light fission fragment (at the lower mass peak in the fragment/distribution curve[7]) where $Z_1 = 39$, $E = 95$ MeV:

$$\left(-\frac{dE}{dx}\right)_{\substack{\text{fission}\\ \text{fragment}}} = 0{\cdot}654 \text{ erg/cm}$$

which is very much larger than that for a helium-3 ion.

Since the energy transferred to the crystal in this way dissipates mainly by ionization and localized heating and hence track formation, we should expect that the helium ion will form a very narrow track which will under most conditions be invisible in the electron microscope. This hypothesis is supported by the fact that no helium-3 tracks have so far been observed in similar specimens of MoO_3 bombarded at low angle (10°) with a radiation dose of 10^{10}–10^{13} particles/cm². At these doses individual particle tracks, if visible, could be resolved. Thus it is fairly certain that the tracks observed here must be due to a heavier particle.

In addition, we can eliminate primary knock-ons as a possible cause by considering the mechanics of a close collision between a helium-3 ion (E = 29 MeV) and an atom of the crystal or grid. In the classical approximation, which is sufficient for our purposes, the differential cross-section for Rutherford scattering of an energetic ion may be expressed in terms of the energy transfer T:

$$d\sigma\,(E, T) = \frac{\pi b^2}{4}\, T_m \,\frac{dT}{T^2}$$

where E is the incident particle energy, b is the collision diameter, and T_m is the maximum energy transfer which can occur in the collision. In a collision between particles of masses M_1 and M_2, and charges Z_1e and Z_2e:

$$T_m = \frac{4\, M_1\, M_2}{(M_1 + M_2)^2}\, E$$

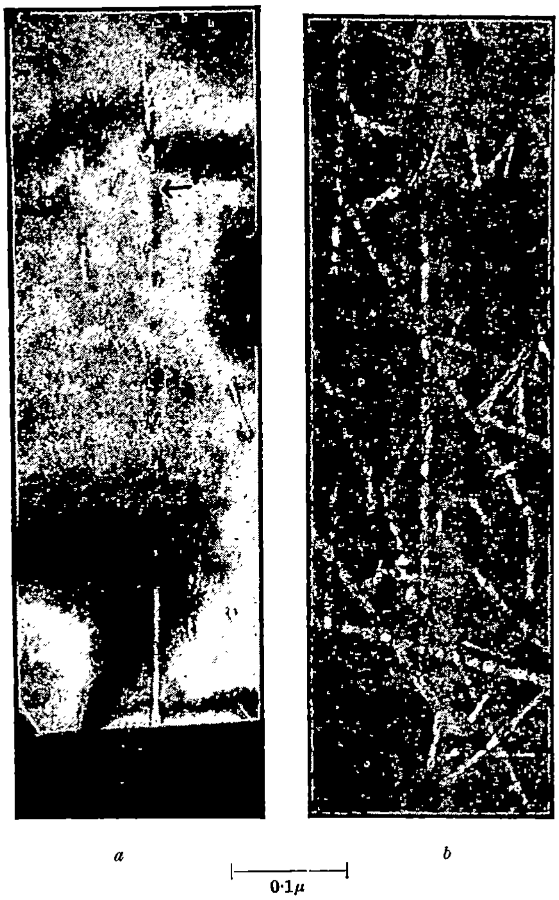

Fig. 2. *a*, Track produced by a recoiling nucleus showing diffraction contrast and a large angle collision (arrowed). The width is much less than in tracks formed by fission fragments (*b*)

and:

$$b = \frac{Z_1 Z_2 e^2 (M_1 + M_2)}{M_2 E}$$

Consideration of the variation of $d\sigma$ with T reveals that the scattering process favours low energy knock-ons. These inevitably carry off much less energy than would be transferred in a head-on impact ($T_m \simeq 4$ MeV), and their rate of loss of energy is therefore not sufficient for track formation.

The removal of this possibility leaves us with the third and most probable cause, namely, the heavy ion end-products of nuclear reactions. The cross-section for a reaction of the form:

$$X + {}^3\text{He} \rightarrow Y + z$$

(where X and Y are heavy ions and z represents one or more light particles) in crystals of the thickness normally used in transmission electron microscopy is negligibly small, even with as high a dose of radiation as has been used in these experiments. This would explain qualitatively why the tracks were extremely rare in isolated thin crystals. The cross-section for reactions in a cluster of crystals thick enough to be opaque to the electron beam is greatly increased, both by the much greater distance travelled by the helium-3 ions in the crystal, and by the fact that the energetic heavy ion products can be emitted at a smaller angle than 90° with the incident beam direction and still form visible tracks in adjacent thin crystals. The probability of heavy ion emission from the nuclear reaction is obviously greatest in a forward direction with reference to the incident beam, and it is quite possible that some of the tracks observed here could result from the large-angle scatter of these ions into the plane of the thin crystals.

Reactions most likely to give rise to the observed tracks are those yielding heavy energetic radioactive ions of isotopes with mass number in the region of that of the crystal atom struck by the helium-3 ion. For example, the following reactions with oxygen atoms in oxides and nuclear emulsions have been observed[8,9]: ${}^{16}\text{O}({}^3\text{He}, d){}^{17}\text{F}$; ${}^{16}\text{O}({}^3\text{He}, p){}^{18}\text{F}$; ${}^{16}\text{O}({}^3\text{He}, n){}^{18}\text{Ne}$; ${}^{16}\text{O}({}^3\text{He}, {}^4\text{He}){}^{15}\text{O}$. The products of reactions such as these are generally unstable, tending to decay with half-lives varying from a few minutes up to several days. In this connexion it is interesting to note that the specimens and backing plates were observed to be radioactive immediately after irradiation. Similar reactions in copper and molybdenum trioxide have been detected, with helium-3 and helium-4 as the incident ions[10–12]. In a reaction of this nature, the incident particle energy and the Q-value of the reaction are shared by the end-products, and thus it is probable that the heavy ion will have energy 10–20 MeV, which is quite sufficient to form a visible track.

Conclusion. The results so far imply that the tracks observed in these crystals are formed as a consequence of collisions between helium-3 ions and nuclei of the crystal or grid atoms, in which penetration of the nuclear potential barrier occurs, leading to transmutation and a high-energy transfer to the product nuclei. If this is the case, we not only have an efficient solid-state detector, but a possible method of investigating the mechanism of track formation. An accurate quantitative treatment of fission-fragment tracks is normally impossible since little is known about the statistics of the particle. The energy and mass can lie at any point on the twin-peaked curve of the fragment distribution, and the energy is further influenced by the depth of uranium foil traversed by the fragment between its point of creation and the surface of the foil[7]. In the case of the ion tracks observed after ^{3}He-irradiation, although the energy can lie within a fairly broad range, the mass may be reasonably estimated to within a few atomic mass units if, as seems possible from differences in track thickness, we can differentiate between ions resulting from a ${}^3\text{He}$–${}^{16}\text{O}$ reaction and those from a ${}^3\text{He}$–${}^{96}\text{Mo}$ reaction. In the reaction with a molybdenum atom, the product heavy ion could have a mass number considerably less than 96, if, for example, 3 α-particles were emitted, but the cross-section of this type of reaction is relatively small compared with those in which the mass change is three or less. Thus it may be possible to compare track parameters such as thickness and frequency of large angle collisions with theoretical predictions in an attempt to discover more about the mechanism of track formation in a binary crystal such as MoO_3.

We thank Dr. F. P. Bowden for help and encouragement, Dr. J. H. Fremlin for valuable discussions and permission to use the cyclotron, and the Ministry of Education (Northern Ireland) for the award of a research grant to one of us (I. McC. T.).

HENBURY IMPACT GLASS: PARENT MATERIAL AND BEHAVIOUR OF VOLATILE ELEMENTS DURING MELTING

By DR. S. R. TAYLOR and P. KOLBE

Department of Geophysics, Institute of Advanced Studies, Australian National University, Canberra

THE nature of the parent material of tektites has been discussed for many years. A basic question is whether the present composition reflects that of the source material, or whether it has been modified during melting, with loss of more volatile constituents. We are concerned here only with elements which will be lost at temperatures in excess of 1,000° C, and exclude the material, such as water, lost at lower temperatures, commonly reported in chemical analyses as 'lost on ignition'. Elements which have been thought to be volatile during the processes of tektite formation include the alkali elements[1,2], zinc, copper[3] and germanium[4]. Other possibilities are lead, thallium and mercury.

In most potential source materials, sodium and potassium will be present at concentration-levels of a few per cent, and the others in trace quantities. The selective loss of these elements would raise some difficulties in identification of the parent material, but would not modify the concentrations of the other elements by more than a few per cent. If there has been no appreciable loss of the volatile elements, the present concentrations can be used to identify possible parent materials. Losses of up to 10 or 20 per cent of the concentrations of the volatile elements will not seriously hinder the search. Some workers[1-3] have attempted to show that tektites may be derived from granitic-type igneous rocks by loss of such elements.

Friedman *et al.*[5] found no evidence for selective loss during fusion of rocks at 2,500° C in air and concluded that "the observed composition of tektites probably reflects the composition of the material from which they came". In extensive investigations of the composition of australites[6,7] no effective depletion of volatile elements such as cæsium and rubidium has been observed. It has not been necessary to invoke such mechanisms to account for the chemical composition of these tektites, which may be matched with that of terrestrial sedimentary rocks. Geochemical examinations of the enigmatic Darwin glass have led to similar conclusions[8].

A useful new approach is to examine the composition of undoubted terrestrial impact glasses and their source material. The extrapolation to the unknown conditions of tektite formation is uncertain, but may be distinctly possible because glass formation probably occurs under a similar range of conditions whether the event is large or small. A further reason for this investigation has been the lack of comprehensive trace element data for impact glasses which has handicapped workers on tektites and other glasses of debatable origin.

Suitable areas to compare impact glasses and their parent materials are rare. At Henbury, Northern Territory, Australia (24° 35′ S.; 133° 09′ E.), the impact of an iron meteorite shower has produced twelve craters and minor amounts of glass associated with the largest crater. This occurrence is well described by Alderman[9] and Spencer[10]. The rock outcropping at the surface is sandstone, dipping south at a low angle. Blocks of an underlying subgreywacke are exposed in the main crater. Glass samples from two areas, one on the crater rim and the other about 100 m north, were collected. The glass occurs as small brown cellular masses. Samples for analysis were obtained by gentle crushing without metallic contact, followed by ultrasonic cleaning and hand-picking of the washed material under a binocular microscope. Eight samples of the sediments were also analysed. Full details of sample localities, descriptions, sample preparation and analytical methods will be reported elsewhere.

A brief comment on the analytical methods is necessary. The major elements were determined by Dr. H. B. Wiik using wet chemical methods. The trace elements were determined by emission spectrochemical methods utilizing standard methods previously developed[11] and used for the analysis of tektites[6,7] and Darwin glass[8]. Instrumental calibration was carried out using interlaboratory standard samples[12]. The high content of iron and nickel in the glasses made it necessary to check commonly used spectral lines for interference by lines of these two elements. A correction for titanium interference by the line at 8518 Å was made for the cæsium analytical line at 8521 Å. This line was resolved from the iron line at 8514 Å. Work is proceeding on the determination of gallium. The line at 2944 Å is subject to nickel interference at the concentrations observed in the glasses, the lines at 2874 Å and 4172 Å are subject to interference by iron lines and the line at 4033 Å is unusable because of the presence of a strong manganese line.

Table 1. MAJOR ELEMENT DETERMINATIONS ON HENBURY GLASS AND SUBGREYWACKE

Columns *B* and *D*, meteoritic iron content removed.
Column *F*, water and carbon dioxide removed.
* Total iron expressed as FeO.

The analytical results obtained answer three questions: the nature of the parent material; the extent of addition of iron, cobalt and nickel from the meteorite; and the effect of melting on the chemical composition of the source material.

Preliminary qualitative spectrochemical analysis showed a close correspondence in composition between the glass and the subgreywackes, except for iron, cobalt and nickel, which were present in much higher concentrations in the glass. The composition of the sandstones was not similar to that of the glass. These conclusions have been confirmed by the quantitative data. A comparison of the major elements, expressed as oxides, is given in Table 1 for the two glass samples and the sediment closest in composition. The high iron content of the glasses is noteworthy. Columns *B* and *D* give the glass composition with the excess iron removed. Results for the non-volatile trace elements are given in Table 2, which also includes data for the major-constituents expressed as elements. There is a close correspondence in composition between glass and sediment except for iron, cobalt and nickel. Using the

sediment data as representing the original composition, the iron/nickel and nickel/cobalt ratios derived from contamination by the impacting meteorite average 18·4 and 12·5. These compare with iron/nickel ratios of 12·8 and 12·1 and nickel/cobalt ratios of 33 and 20 from published analyses of the Henbury iron[10]. The match for the other trace elements is close, with chromium and vanadium higher and titanium, zirconium and yttrium lower in the glass compared with the sediment. Probably the parent material of the glass was slightly richer in clay and poorer in resistant minerals such as zircon than the sediment listed.

Results for the 'volatile' elements are given in Table 3. The composition of the two glasses and the sediment is very similar. Sodium is about 20 per cent higher in the sediment. Lithium, potassium and rubidium are close in concentration, and the volatile element, cæsium, is higher in the glasses than in the sediment. The higher concentrations of cæsium parallel the higher copper, vanadium, chromium and magnesium contents, which may be interpreted to indicate that the source material of the glass was slightly higher in clay content than the sediment listed. The volatile element, lead, is present at similar concentrations in both glasses and sediment. It seems clear from an examination of Table 3 that no significant depletion of the 'volatile' elements has occurred during glass formation. The slight differences observed may be readily attributed to minor differences in composition of the source rock. The results do not exclude losses of a few per cent, but limit selective distillation to a minor role, not materially affecting the composition. The changes in composition are limited to the addition of iron, cobalt and nickel from the impacting meteorite.

The results considered here strengthen the interpretation based on internal compositional evidence that the compositions of australites[6,7] and Darwin glass[8] have not been seriously modified by loss of the more volatile constituents, so that their present compositions reflect that of the parent materials.

We thank Dr. H. B. Wiik for analyses of the major element and Mrs. A. Halsey for carrying out the spectrographic determinations.

LAYERED INTRUSIONS OF THE GILES COMPLEX, CENTRAL AUSTRALIA

By DR. R. W. NESBITT and DR. A. W. KLEEMAN

Department of Geology and Mineralogy, University of Adelaide, South Australia

THE Giles Complex[1] consists of a series of basic–ultrabasic layered intrusions of Archæan age, which are situated in Western Australia and the north-west corner of South Australia. Basic igneous rocks were first recorded from the area by Basedow[2], and later examination of this material[3] showed their ultrabasic nature. The investigation recorded here deals with those intrusions found in the South Australian part of the complex, with particular emphasis on the largest of these at Mt. Davies (Fig. 1).

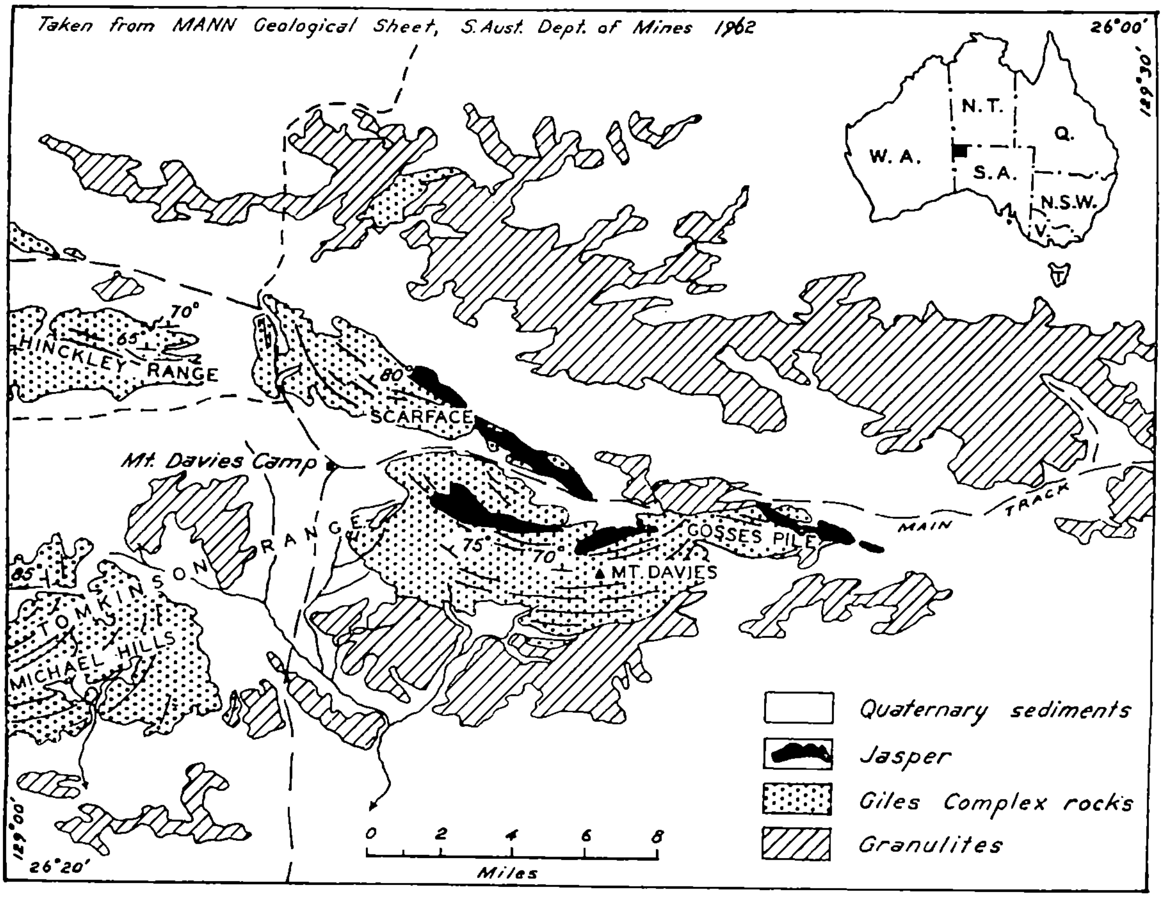
The Mt. Davies intrusion is an east-west trending elongate body about 10 miles long and 3 miles wide. The intrusion is marked by spectacular compositional banding which in the main body of the intrusion dips north at 70°–80°. The rocks are almost unweathered, making them ideal for petrological and geochemical investigation.

Contacts with the country rocks are often faulted, but the common presence of biotite in the igneous rocks at some of the contacts, suggests that these represent the true margins of the body, which have been contaminated by the incorporation of acid granulites.

Petrological and geochemical investigations of the intrusion are at an early stage of development, and although there has been a major specialized investigation of the intrusion by a commercial organization and by the South Australian Department of Mines, no systematic petrological description has been published.

Some chemical analyses on gabbros and norites have already been made, and olivine and feldspar compositions determined. The olivine compositions were determined using the method of Yoder and Sahama[4] with the modification that zinc oxide instead of silicon has been used as an internal standard. The results indicate a progressive enrichment in the iron molecule fayalite from 5 per cent in the ultrabasic zone to 30 per cent in the olivine norites on the south side of the intrusion.

It is considered that if the layering in the body is gravitational in origin (that is, originally close to the horizontal) then the mineralogy indicates that the rocks are younger to the south and so are overturned. This leads to a tentative subdivision of the intrusion into: (1) ultrabasic zone; (2) olivine-enstatite-gabbros grading



Taken from MANN Geological Sheet, S.Aust. Dept. of Mines 1962

Fig. 1

up into (3) olivine-norites with prominent anorthosite bands, the total thickness being approximately 15,000 ft. The ultrabasic zone consists of repeated layers of green clinopyroxenites, olivine clinopyroxenites, black anorthosites and more normal olivine gabbros. The whole sequence of ultrabasics and olivine-enstatite-gabbros is remarkably free of opaque material, and magnetite does not appear until the olivine-norites of the upper part of the intrusion.

Optical investigations on the plagioclases indicate that the composition remains fairly constant in the ultrabasic and olivine-enstatite-gabbro zones (An_{86-80}) but changes in the olivine-norites, becoming more albitic (An_{70}), especially toward the southern contact.

Immediately north of the ultrabasic zone there is a zone of jasper which separates the main body of the intrusion from about 6,000 ft. of layered olivine-norites and picrites, again dipping north at about 80°. The jasper occupies a major fault area and the rocks on either side of this fault are remarkably dissimilar. This northern sector is characterized by fine-scale banding, slump structures and high concentrations of magnetite and ilmenite, and it is thought that these rocks are not part of the Mt. Davies intrusion, but are the sheared portion of another body. Olivine determinations show a range of Fa_{25-35}.

A programme of chemical analyses has been commenced and initial results are presented in Fig. 2. The specimens so far analysed are all olivine gabbros or olivine-norites from the main part of the intrusion and from the layered gabbros of the ultrabasic zone. The overall iron enrichment observed in the olivines toward the south margin of the body is substantiated by analysis of five specimens taken from varying parts of the intrusion. The values of MgO, total iron as FeO, and total alkalis are plotted in Fig. 2 to indicate the trend in specimens from the northern margin (excluding the zone north of the jasper) through to a rock which occurs about 5,000 ft. from the southern contact. The increase in total iron is from 2·1 to 4·3 per cent and there is little doubt that subsequent analyses of material higher in the intrusion (that is, toward the south) will continue to show this trend.

Fig. 2 is also of significance in that it indicates the unusual deficiency in iron exhibited by the rocks of the Mt. Davies intrusion. As yet we have been unable to find any described examples of gravity stratified intrusions in which the ratio of total iron to magnesium is so low. For comparison, the trends of Stillwater[5], Skaergaard[6,7],

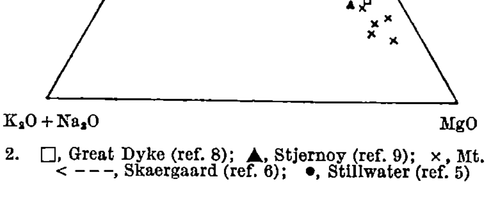


Fig. 2. □, Great Dyke (ref. 8); ▲, Stjernoy (ref. 9); ×, Mt. Davies; < - - -, Skaergaard (ref. 6); ●, Stillwater (ref. 5)

the Great Dyke of Southern Rhodesia[8], and Stjernoy in Norway[9] are plotted.

The importance of the Mt. Davies body appears to lie in its possible contribution to the relationships of the alpine-type and stratiform complexes[10,11]. Thus its affinities to the stratiform bodies may be listed as: (1) regular layering which is continuous over several miles; (2) cryptic layering especially exhibited by the olivines; (3) the absence of any large quantities of dunite or peridotite; (4) the preponderance of pyroxene over olivine in the ultramafic zone; (5) lack of stress effects in olivines except at the margins; (6) presence of abundant anorthosites. On the other hand, it also bears relationships to the 'alpine-type' complexes: (1) very high MgO/FeO ratio, not only in the ultramafic rocks but also in the gabbros; (2) forsterite-rich olivines; (3) almost vertical layering and sheared contacts; (4) the absence of rocks more acidic than bytownite gabbro.

Further work in the area is planned to elucidate the relations between the various intrusions and their relationship to the country rocks and a major petrological programme is envisaged.

We thank the Nuffield Foundation for financial support and the Department of Aboriginal Affairs and the Weapons Research Establishment, South Australia, for their cooperation. Chemical analyses were carried out by the Australian Mineral Development Laboratories.

RATE OF ACCUMULATION OF SNOW AT THE SOUTH POLE AS DETERMINED BY RADIOACTIVE MEASUREMENTS

By E. PICCIOTTO and G. CROZAZ
Service de Géologie et Géochimie Nucléaires, Université Libre de Bruxelles
AND
W. DE BREUCK
Laboratorium voor Fysische Aardrijkskunde, Rijksuniversiteit te Gent

THE importance and the difficulties of estimating the annual rate of accumulation of snow on the Antarctic polar plateau have been stressed by various authors[1,2]. These difficulties are basically due to the very low annual rate of accumulation which could give rise to complete disappearance of an annual or seasonal layer by wind erosion or by some other mechanism. Thus all methods based on identification of annual layers would tend to under-estimate the number of years, whether these methods be stratigraphic or isotopic.

In order to overcome this difficulty two methods based on radioactive measurements have recently been proposed; these methods avoid the subjective interpretations inherent in glaciological and isotopic methods.

The first method[2] is based on radioactive fall-out from the Castle thermonuclear bomb test which is used to identify a reference-level corresponding to the 1954–55 austral summer. This method could be used to measure the mean accumulation over the past nine years. The second method[3,4] is based on the radioactive decay of the lead-210 contained in the precipitation. This method would normally allow the dating of the snow layers for up to one hundred years in the past.

During the course of a summer campaign supported by the U.S. Antarctic Research Program (U.S. National Science Foundation), two of us (E. P. and W. D. B.) were able, in December 1962, to collect a series of samples of snow and firn to be investigated by both methods.

A number of samples, at depths of up to 26 m, were collected in the 'Snow-Mine'[5] of the Amundsen–Scott South Pole Station and were brought frozen to Belgium.

Estimations of the rate of accumulation of snow at the South Pole published so far are based on three groups of results:

(1) *Stratigraphic observations.* The most extensive are those of Giovinetto[5], which deal with the 26-m section of the 'Snow-Mine' representing a period of more than two hundred years. He reports a mean annual accumulation of 6·6 cm of water during 1760–1947 with, however, an annual rate of 7·4 cm over the past hundred years.

More recent observations[6] confirm the figure of 7·0 cm of water as the annual rate over the past few years.

(2) *Direct measurements carried out, since 1957, on stakes placed in the vicinity of the station.* The mean value of these measurements kindly communicated by L. Aldaz, indicates an accumulation of 20 cm/yr. in the relative level, which, taking into account a density of 0·35 for the surface snow, confirms the value of 7·0 cm of water.

(3) *Variations in the oxygen isotope ratio.* Sharp and Epstein[1] note a systematic disagreement between the values of the annual accumulation deduced from their measurements of the O–18/O–16 ratio and those obtained by direct measurement or deduced stratigraphically at various locations in West Antarctica. They suggest the possibility that the accepted rate of accumulation for the whole West Antarctica may have been under-estimated by a factor of 2.

They put forward an annual rate of accumulation of water at the South Pole of the order of 15 cm. This figure results from the analysis of an 80-cm ice section, showing only 3 isotopic alternations.

This article presents the results obtained by our stratigraphic observations, and by the measurements on the fission products and on lead-210.

(*a*) *Stratigraphy.* Fig. 1 presents the stratigraphic profile of a glaciological pit dug in the north-east quadrant, about 500 m from the Amundsen–Scott South Pole Station.

The stratigraphic features of the snow cover in this area have been previously described[5-7]. The identified summer layers are shown in Fig. 1. The average annual accumulation deduced for the period 1951–62 inclusive is 7·5 cm of water. One or more year-level having probably been missed, this value must be considered an upper limit. For the period 1955–62 inclusive, for which the stratigraphy is more clearly marked, the average annual increase is 6·3 cm.

(*b*) *Fission products.* Fig. 1 also shows the values of the gross β-activity of the snow as a function of depth in the same pit (cf. ref. 2 for experimental details and interpretation). According to the results obtained at the King Baudouin Base, the sudden increase in the β-activity noted above the − 145-cm level should correspond to early 1955. The results here reported confirm this con-

Table 1. Independent Estimations of the Annual Accumulation at the South Pole

Annual interval (estimated)	Method of measurement	Snow accumulation (cm)	Water equivalent (cm)	Ref.
Feb.– Nov. 1962	Direct ('New Field', 140 stakes)	20	7·0	L. Aldaz (private communication)
Feb. 1958– Nov. 1962	Direct ('Old Field', 36 stakes)	18·5	6·6	,,
(1947–1850)	Stratigraphy ('Snow-Mine')		7·4	Giovinetto (ref. 5)
(1958–1954)	0–18/0–16		15	Sharp and Epstein (ref. 1)
(1963–1951)	Stratigraphy	20	7·5	Present work
(1963–1955)	Fall-out	17·5	6·5 ± 0·5	,, ,,
(1963–1850)	Lead-210		6 ± 1	,, ,,

clusion and are in good agreement with the stratigraphic interpretation of the upper 140 cm. They indicate a mean annual accumulation of 6·5 ± 0·5 cm of water between 1955 and 1962.

(*c*) *Lead*-210. We have measured the lead-210 activity on a 2-m deep section covering the 1962–54 interval and on 60-cm thick specimens collected in the 'Snow-Mine' at intervals of about 4 m up to a depth of 26 m. The experimental details are described elsewhere[4]. The results are shown in Fig. 2 in which the logarithm of the lead-210 activity is plotted with respect to the depth, expressed in cm of water.

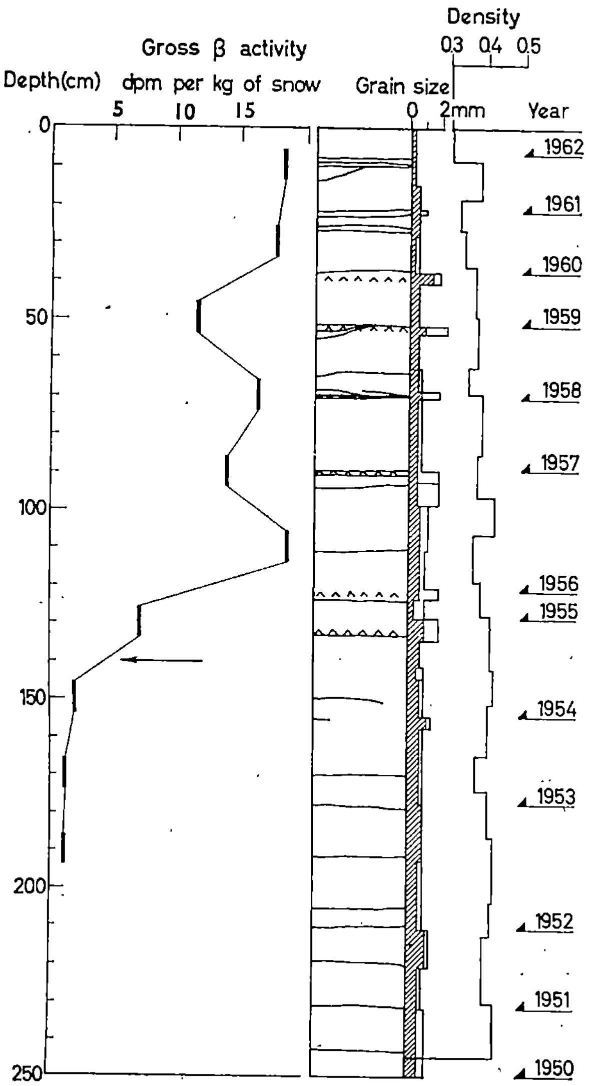

Fig. 1. South Pole: 'Pit 1'. Stratigraphic profile and gross β-activity. The interpretation of the stratigraphic profile in terms of annual layers is given on the right side of the figure

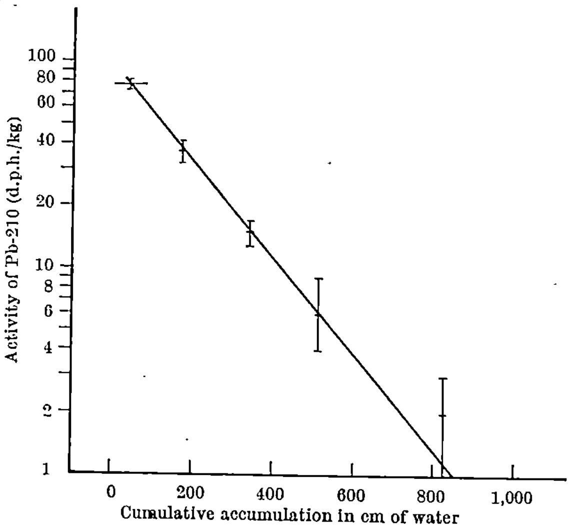

Fig. 2. South Pole: 'Snow-Mine'. Variation of the lead-210 activity in the firn as a function of depth. The slope of the line, in semi-logarithmic co-ordinates, corresponds to an annual accumulation of (6 ± 1) cm of water

It will be noticed that, within experimental error, the lead-210 activity decreases exponentially with the depth, the most plausible interpretation[3,4] being that the rate of accumulation of the water and the initial activity of lead-210 in the snow have remained constant over the past hundred years. Taking the half-life of lead-210 as 21·4 years[8], the mean annual accumulation over the past century is found to be 6 ± 1 cm of water.

This value is slightly lower than that deduced by Giovinetto from the 'Snow-Mine' stratigraphy for the same period, but confirms, however, the excellent quality of his observations carried out under particularly difficult conditions. The results are summarized in Table 1.

In conclusion, three completely independent methods (stratigraphy, fission products and lead-210) lead to a mean value of the annual rate of accumulation between 6 and 7 cm of water at the South Pole. The two former methods lead to an average over the past nine years, whereas the lead-210 activity decay (in agreement with the stratigraphic observations of Giovinetto) indicates that this average has not appreciably varied over the past hundred years.

The value of 15 cm of water put forward by Sharp and Epstein does not appear to be acceptable. Possible reasons for this disagreement have been already discussed[9].

This work was carried out under contracts *AA*-422 and *AA*-487 with the U.S. Antarctic Research Program, National Science Foundation, and was supported by the U.S.A.R.P. and the Task Force 43, U.S. Navy. Financial support was also supplied by the Institut Interuniversitaire des Sciences Nucléaires de Belgique.

A part of the equipment used in the work is the property of the 'Association EURATOM Université Libre de Bruxelles-Comitato Nazionale per l'Energia Nucleare', contract 013-61-7 *AGEC*.

We thank Mr. J. Deschamps for help in carrying out the radioactive measurements.

LETTERS TO THE EDITOR

PHYSICS

Bearing of Recent Experiments on the Special and General Theories of Relativity

In a recent communication Dr. L. Essen[1] concluded that special relativity cannot be applied to a rotating system. Jennison[2] and Synge[3] have previously treated the problem considered by Essen and have shown it to be consistent with special relativity. As the application of special relativity in this context is of considerable importance and in order to clarify its correct application the following points should be noted.

(1) Any point in the system may be considered to exist instantaneously in a Lorentz frame. This frame only applies momentarily to the elementary locality or neighbourhood around the point but is sufficient to establish local time and angular measure.

(2) If a signal is transmitted from any point participating in steady-state rotation and received by another point in the same rotating system, then, over any distance exceeding the elementary size of a Lorentz locality and within the range of velocities $\omega r \leqslant c$, the Lorentz frame associated with the neighbourhood of transmission always differs from the Lorentz frame associated with the neighbourhood of reception.

(3) The ray angle associated with the locality of transmission is related to the ray angle in the locality of reception by the usual relativistic aberration for the angles in the Lorentz frames appropriate to the velocities of the localities concerned.

(4) When the appropriate aberration is introduced the Doppler shift that is computed is precisely that observed in the Mössbauer experiments and predicted by general relativity. No Doppler shift occurs for transmission and reception between any two points equidistant from the centre, for the angles of transmission and reception are precisely those which are necessary for the transmission from one Lorentz frame to be received in another at the identical frequency.

(5) One should exercise care in considering distances in the Lorentz frame associated instantaneously with a point in the system, for the Lorentz frame embraces the conditions in only a vanishingly small locality of the rotating system. Only the identical instantaneous velocity and not the radius is required for the computation of the Doppler shift and local ray angles by special relativity.

It is in this respect that special relativity may be misleading, but not incorrect.

Consider the velocity of an inertially radial pulse of light relative to a rotating system of radius r and angular velocity ω. In a frame of reference containing the centre let the group velocity of the pulse relative to the system (and the system relative to the pulse) be c. Then the tangential velocity of the pulse in the system is ωr and the radial velocity $= c\left(1 - \frac{\omega^2 r^2}{c^2}\right)^{\frac{1}{2}}$. This defines the light path in the rotating system as a circular arc of length $s = \frac{c}{\omega} \sin^{-1} \frac{\omega r}{c}$.

It is now helpful to use brackets and subscripts to indicate where in the rotating system the measurements shall be made. Thus the rotating radius measured from the centre:

$$(r)_0 = \frac{c}{(\omega)_0} \sin \frac{\omega s}{c} = r$$

But the rotating radius measured from a rotating point at inertial radius r is given by:

$$(r)_r = \frac{c\left(1 - \frac{\omega^2 r^2}{c^2}\right)^{\frac{1}{2}}}{\omega} \sin \frac{\omega s}{c}$$

$$= \frac{c}{(\omega)_r} \sin \frac{\omega s}{c} = r\left(1 - \frac{\omega^2 r^2}{c^2}\right)^{\frac{1}{2}}$$

$(\omega)_r = \dfrac{\omega}{\left(1 - \frac{\omega^2 r^2}{c^2}\right)^{\frac{1}{2}}}$ is the rate at which the universe appears to rotate to a rotating observer at the rotating radius $(r)_r$. The unit of time is taken as the ticking of his own (standard) atomic clock and the unit of distance as the wave-length that he associates with the same clock. The relationships for $(\omega)_r$ and $(r)_r$ may also be obtained by considering radar signals transmitted and received by a single observer having an appropriate local time and restrained at constant distance from the centre. In individual inertial systems there appears no transverse relativistic contraction despite the dilatation of time, for when the observer is considered to be in motion relative to the target, the ray geometry introduced by the finite transit time cancels the contraction that might be expected by radar. The rotating system, however, is constrained so that the observer is maintained at the same distance from the target at all times and the result follows from the removal of the geometric factor. The radial contraction may also be demonstrated by considering signals continuously propagated between two radar transponders, one at the centre and the other in the rth ring, each triggering the other so that they set up a regular series of pulses. The pulse repetition frequency may be measured at each end in terms of local atomic clocks and thus gives the radar range; as the frequency of the clocks may also be transmitted for comparison it will be observed that the radar range contracts in the manner predicted. Similarly, if a signal is made each time that a point in the rth ring passes over a fixed point in the inertial system of the centre and this information is transmitted to the centre together with the ticking of a local clock, the increase in angular velocity is immediately apparent.

It should be noted that the product ωr is always equal to the associated product $(\omega)_r\ (r)_r$ for a given point or ring in the steady-state system, but:

$$(\omega)_r^2\ (r)_r = \frac{\omega^2 r}{\left(1 - \frac{\omega^2 r^2}{c^2}\right)^{\frac{1}{2}}}$$

Whence, multiplying both sides by m_0:

$$m_0(\omega)^2_r\ (r)_r = \frac{m_0}{\left(1 - \frac{\omega^2 r^2}{c^2}\right)^{\frac{1}{2}}}\ \omega^2 r$$

The left-hand side of this equation is the correct expression for the centrifugal force at the point where it is considered to act, and where the proper angular velocity and radius are $(\omega)_r$ and $(r)_r$ respectively.

It is of interest to consider the ray curvature and limiting radius (ref. 2, Fig. 3 of which requires slight amendment), in the plane normal to the spin axis, of a particle which has an independent spin parallel to the axis of rotation in a system which itself has a very high value of ω at the centre and therefore a much higher value at the particle. The theory predicts the possibility of completely isolating the particle in this plane, while maintaining the steady-state rotation, by virtue of the combined spin at the particle. The application of these principles to the understanding of the quantization of angular momentum deserves some attention.

Finally it is interesting to note that the observed geometry is such that a disk remains a disk under steady state rotation.

Note added in proof. Essen has courteously shown me his reply; the Lorentz frames in my treatment are permanent, only the co-existence (or coincidence) is fleeting.

R. C. Jennison

Department of Physics,
University of Manchester.

[1] Essen, L., *Nature*, **202**, 787 (1964).

[2] Jennison, R. C., *Nature*, **199**, 739 (1963).

[3] Synge, J. L., *Nature*, **198**, 679 (1963).

Dr. Jennison quotes only a part of my conclusion and it seems to me that he does not answer any of the points I raised.

In paragraph (1) of his communication it is stated that any point in the system can be considered to exist instantaneously in a Lorentz frame. In the experiment, however, the absorber is continuously accelerated and Jennison's assumption is therefore not in accord with the experimental conditions.

His definitions of 'instantaneously' and 'elementary locality' are both strange and variable. In his paragraph (1) the duration and extent are sufficient for local time to be established. For this the procedure described by Einstein must be adopted. A light signal is sent from the local clock to the distant clock and back again. The time is thus that of the double journey—which is double the time occupied in the actual experiment under discussion—and the 'elementary locality' includes the absorber and emitter. In (2), on the other hand, it is stated that for a distance exceeding the 'elementary size of a Lorentz locality' the absorber and emitter are in different frames. In (5) the elementary locality is called 'vanishingly small'. The assumptions in (2) and (5) thus contradict those in (1). Those in (1) cause the acceleration to be neglected while those in (2) and (5) enable the effects to be attributed to the acceleration. This is the very weakness in Einstein's argument to which I directed attention.

Later in his communication Jennison uses the practice so popular in discussions on relativity of propounding an imaginary experiment and of stating the result obtained. Although this artifice may occasionally have some illustrative value, it is in general useless and misleading. It is useless because an imaginary experiment cannot yield any information, and misleading because it appears to provide experimental support for what are mere assumptions. Jennison, for example, discusses the results observed in his experiment. In imaginary experiments there are neither observers nor observations and the use of such expressions is simply a misuse of language. Scientific theories, if they are to be of value, must be based on the results of actual experiments.

Scattering and Attenuation due to Snow at Optical Wave-lengths

The narrow beam-widths obtainable with coherent light permit one to examine forward scattering caused by atmospheric effects in some detail. For example, it is found that inhomogeneities of refractive index in the otherwise clear atmosphere give rise to considerable broadening of a narrow beam. However, when heavy snow is falling, scattering and the ensuing attenuation of the optical wave are caused predominantly by the flakes; this also holds true in propagation through droplets of fog and rain.

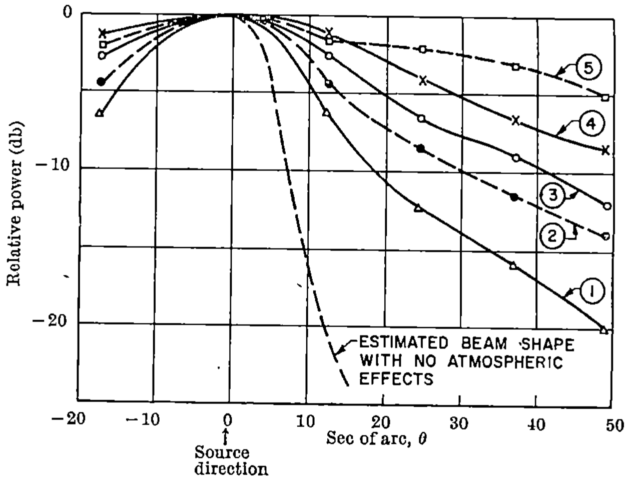

Fig. 1. Beam broadening due to snow: λ, 0·63μ; path-length, 2·6 km. Data of 2/10 and 2/11/64. Excess attenuations in curves 1–5 are 3·5, 5·0, 13·6, 15·6 and 17·9 db/km respectively, corresponding to increasingly heavy snowfalls. The attenuations are measured at dead reckoning, that is, with the receiving aperture on the maximum of the beam pattern ($\theta = 0$)

Fig. 1 shows beam patterns measured at a wave-length of 0·63μ over a path 2·6 km in length. The source consists of a helium–neon optical maser operating in several modes, and a cassegrainian telescope of 3·5 in. in diameter; the receiver is a 2-in. telescope with a photomultiplier. If the intervening path were vacuum, this combination would produce a half beam-width at the −5 db points of about 5 sec of arc as indicated by the narrow dashed curve. The broadening shown in curve 1, where the snowfall and corresponding attenuation are quite light, is due mainly to refractive effects, that is to say, it does not differ much from beam patterns measured during clear weather. However, as the rate of snowfall and attenuation increase, the beam-width does likewise, as indicated by curves 1–5. The patterns are normalized at $\theta = 0$. In curve 5, corresponding to an excess attenuation of about 18 db/km, the −5 db point of the pattern has increased to almost 50 sec of arc and the beam appears quite flat.

Although beam-broadening due to snow is a readily measurable effect, its onset occurs when the attenuation is fairly high. On the other hand, in the case of rain, broadening effects are observable at much lower attenuations; this is because raindrops are more efficient than snowflakes in forward scattering, the latter suffering from poor geometry and, more often than not, random orientation. Unfortunately, consistent data on beam-broadening due to rain are not obtained as readily as those of snow because of the time variability and inhomogeneity in rainfall along a given path.

Effect of Precompression on the Critical Tension of Liquids

A prior application of pressure may alter the properties of a liquid when subjected to tension. Harvey[1] found that precompression of water up to a pressure of 1,000 atm. increased its ability to withstand tension. In his experiments the tension was generated by means of a hammer blow, that is, the liquid was subjected to stressing under 'dynamic' conditions. In our work we have applied tension under 'static' conditions and have investigated the effect of precompression using the Berthelot tube method described by Temperley and Chambers[2].

Briefly, a Berthelot tube consists of a cylinder, closed at both ends, and is almost completely filled with the liquid under investigation. When this tube and its contents are heated the liquid expands at a greater rate than the tube and fills the tube completely at a certain temperature t_f, the 'filling' temperature. When the tube is later allowed to cool the liquid adheres to the walls and continues to fill the tube at temperatures below t_f. Thus as the temperature falls below t_f a gradually increasing tension is set up in the liquid until it eventually ruptures at a temperature t_b, the 'breaking' temperature. At the temperature t_b the sudden release of tension is accompanied by a sudden increase ΔV in the external volume of the Berthelot tube. The value of the critical tension T in the liquid just before the break can be estimated if ΔV can be measured. Furthermore, the value of T will depend on t_b; for a given Berthelot tube, the lower t_b the greater the critical tension set up and vice versa.

To investigate the effect of precompression on the value of t_b for water, a sealed steel Berthelot tube was chosen the t_f of which was previously determined as 59·5°C. The tube was then heated slowly to a temperature above t_f. As the temperature rose above t_f the water in the tube became subjected to a pressure which increased as the temperature rose. It can easily be shown that the internal pressure P at any temperature t' ($> t_f$) is given in atm. by:

$$P = (\beta - \alpha)\,\Delta t/K \qquad (1)$$

where $\Delta t = (t' - t_f)$, α is the coefficient of cubical expansion of steel, β that of water and K the compressibility of water in atm.$^{-1}$ over that range of temperatures. If such a precompression resulted in a change in the critical tension this should be accompanied by a corresponding change in the breaking temperature t_b. The results of one set of such experiments are shown in Table 1.

Table 1

Δt (° C)	P (atm.)	t_b (° C, mean of four readings)
5·6	80	51·7
10·8	146	51·6
15·3	204	51·6
21·1	286	52·0
25·8	350	51·7
30·5	414	51·9

The values of P in the second column were calculated from equation (1). From the last column it is seen that a precompression of the water of up to 414 atm. had no appreciable effect on the breaking temperature.

Again the length of time for which this maximum pressure of 414 atm. was applied had no significant effect on t_b. This was seen in another series of experiments in which the temperature t' was kept constant at 90° C for varying periods of time τ; the results are summarized in Table 2.

Table 2

τ (h)	t_b (° C, mean of four readings)
0·25	51·8
1·0	52·0
2·0	51·9

We conclude that a precompression of water to pressures of the order of 400 atm. had no discernible effect on the value of the critical tension set up in it. It is possible that the explanation for the difference between these results and those of Harvey lies in the fact that the tension in the water is built up far more slowly in our experiments than in those of Harvey. The matter is by no means straightforward and requires further investigation.

Preparation of Spherical Caps for Use on Terrestrial Globes in Investigations of Palæomagnetism and Continental Drift

In many different fields of geophysics and geology it would be convenient to be able to plot data on a terrestrial globe and then move the plotted data over the globe. For example, anyone interested in seeing how good the fit between the east coast of South America and the west coast of Africa really is would like to be able to trace an outline of South America on a transparent spherical cap and then move this outline against Africa.

Carey[1] used a terrestrial globe and a mould with the same radius of curvature turned from Huon pine. He stretched a suitable tracing plastic across this mould, fixed the film in place by a press and moulded the plastic to the shape of the globe by using boiling water and a drumstick swab. The moulded plastic film could be used for tracing directly from the globe.

I use the 12-in. terrestrial globes of the National Geographic Society. These globes are handy in use because there is no fixed axis which can get in the way and because they show the bathymetry of the oceans. They are large and accurate enough for rough work in continental drift and palæomagnetism.

A mould of plaster of paris was made from this globe. First, however, the globe was given two coats of clear plastic varnish which ensured that the entire globe was absolutely waterproof. A 16 in. × 16 in. box, 5 in. high, was made of 0·5 in. plywood, and this was filled with best quality plaster of paris. The globe was pressed into the plaster and held there for some time, so that a spherical cap mould with a semi-angle of about 50° resulted, which is large enough to accommodate every continent except Eurasia. After the plaster had set the undamaged globe could be removed, and the top surface of the block was scraped flat.

An arrangement was then made so that the space between the plaster mould and a plastic film lying flat on top of the mould could be partly evacuated by means of a vacuum pump. In an earlier arrangement, four horizontal tubes were used about 0·75 in. below the rim of the mould. In a newer model, there is only one tube which comes up vertically through the plaster and ends flush with the surface of the mould at its deepest point.

For the actual moulding two different processes are available—a wet process and a dry process. For the wet process, which is that of Carey[1] with vacuum suction added, a 16 in. × 16 in. piece of tracing plastic is stretched across the mould with its matt surface down and clamped in place by a circular wooden ring which has a sponge rubber gasket on its lower surface. Near-boiling water is poured on, vacuum applied and, without much rubbing, a perfect spherical cap can be moulded. The hot water is then gradually replaced by cold water with the vacuum still applied so that the plastic becomes firm again and preserves its shape.

One difficulty encountered in the wet process is that it is not always easy to obtain locally types of tracing plastic which become sufficiently plastic at temperatures less than 100° C as the present trend is towards dimensionally extremely stable tracing plastics. For this reason I now use a dry vacuum moulding process. The tracing film with its matt side down is stretched across the mould and firmly clamped in place as described before. The tracing film is then heated gently by means of heat lamps or any other source of radiant heat (two 250-W brooder lamps were used), vacuum applied and a perfect mould is made in a few minutes.

Though these spherical caps, on which one can trace and erase, are useful for many purposes, they are particularly useful for the fitting of land forms and geology in investigations of continental drift, and for plotting palæomagnetic results. For example, one may plot on one or several combined spherical caps the outline of a continent and the appropriate palæomagnetic pole position for a given period, and repeat this for all continents for the same geological period. One may then attempt a reconstruction of the ancient position of the continents by making the pole positions coincide (for example, on an inverted thumb tack fixed at the present geographic north pole of the globe). Each continent is then in its correct latitude and is oriented correctly. By rotating the continents around the common pole, the uncertainty in relative longitude can be fully explored. This may be repeated for every suitably documented geological period.

CRYSTALLOGRAPHY

X-Ray Scattering by Irradiated Single Crystals of Potassium Permanganate

HIGH-ENERGY radiation interacts with crystalline solids in a variety of ways, but in general the result is the creation of damage in the solids. Among the effects which may be produced is the creation of localized static lattice defects, that is, defects which are small in three dimensions, namely, interstitials, vacancies, or agglomerates of only several atoms at the most. Theoretical calculations of the X-ray diffraction effects to be expected when lattice atoms are given small displacements from their lattice sites have been carried out by Zachariasen[1], Ekstein[2] and Matsubara[3]. All show that such defects lead to the production of diffuse maxima surrounding the sharp Bragg reflexions at the reciprocal lattice points (relp).

Huang[4] has given a general theory of displacement disorders and their X-ray effects. He has considered the case of spherically symmetric elastic singularities in a face-centred cubic lattice and has predicted the following X-ray scattering effects: (1) an isotropic expansion of the lattice; (2) an artificial temperature factor; (3) no broadening of the Bragg reflexions; (4) diffuse scatter surrounding the reciprocal lattice points; the region of scatter taking the form of a lemniscate.

Konazaki[5] has also calculated the X-ray scattering effects due to lattice defects. Several examples were treated in the case of a face-centred cubic lattice, and it was found that there are two possible types of diffuse maxima around a reciprocal lattice point. One is the lemniscate type and the other is the ellipsoid type, showing a closed surface surrounding the reciprocal lattice point. In general, in cubic crystals isolated defects (vacancies or interstitials) show the lemniscate, and pairs of defects the ellipsoid. Expansion of the lattice was also predicted due to distortion around the defects.

Effects of the type predicted here have been observed to varying degrees in neutron-irradiated boron carbide, diamond, silicon carbide and magnesium oxide crystals[6]. The artificial temperature factor was not very strong with magnesium oxide. Lattice expansions of the order of 1 per cent were observed in irradiated diamond and silicon carbide while that in magnesium oxide was about 0·1 per cent. Pronounced diffuse scattering with the diffuse reflexions being roughly ellipsoid in shape was also found. Rochelle salt irradiated with cobalt-60 γ-rays (dose $3{\cdot}1 \times 10^7$ r.) also showed pronounced diffuse reflexions[7]. The diffuse reflexions are not diminished in intensity at liquid air temperature.

Pre-irradiation of crystals of potassium permanganate by cobalt-60 γ-rays produces crystal damage, which has a profound effect on the subsequent isothermal decomposition[8]. In an attempt to determine the nature of the radiation damage X-ray diffraction investigations have been made of heavily irradiated (500 Mrads) single crystals of potassium permanganate. The following lattice expansions were found: *a*, 0·21 per cent; *b*, 0·31 per cent; *c*, 0·45 per cent. No observable artificial temperature factor is apparent, but pronounced diffuse scattering is present. Laue photographs were taken with the crystal mounted with the *b* axis (needle axis) perpendicular to the X-ray beam (unfiltered copper radiation, 40 kV, 20 m.amp). A flat-plate camera loaded with Kodak 'Industrex' film was exposed for 4 h at a distance of 4 cm from the crystal, which was rotated 5° between successive exposures. The resulting photographs showed a large number of pronounced diffuse maxima. In Fig. 1, a similar set of photographs, but with smaller angular rotations, indicate the nature of the diffuse reflexions associated with the 210 relp. Fig. 1(*a*) shows the appearance of the 210α diffuse spot. Fig. 1(*b*) shows the 210β diffuse reflexion, and the Laue reflexion (*L*) approaching the 210α diffuse spot. Coincidence of the latter two spots occurs in Fig. 1(*c*), and of 210β diffuse and Laue spots in Fig. 1(*d*). Oscillation and stationary crystal photographs of irradiated and unirradiated crystals using filtered (Ni) copper radiation confirmed the location of the diffuse maximum as being at the 210 relp. The full three-dimensional form of the diffuse maxima around the relps is being investigated. It is suggested that the observed effects are due to the breaking of the Mn–O bonds in MnO_4 with the production of oxygen vacancies and oxygen interstitials. Difference Fourier syntheses of irradiated and unirradiated crystals are being computed to test this possibility.

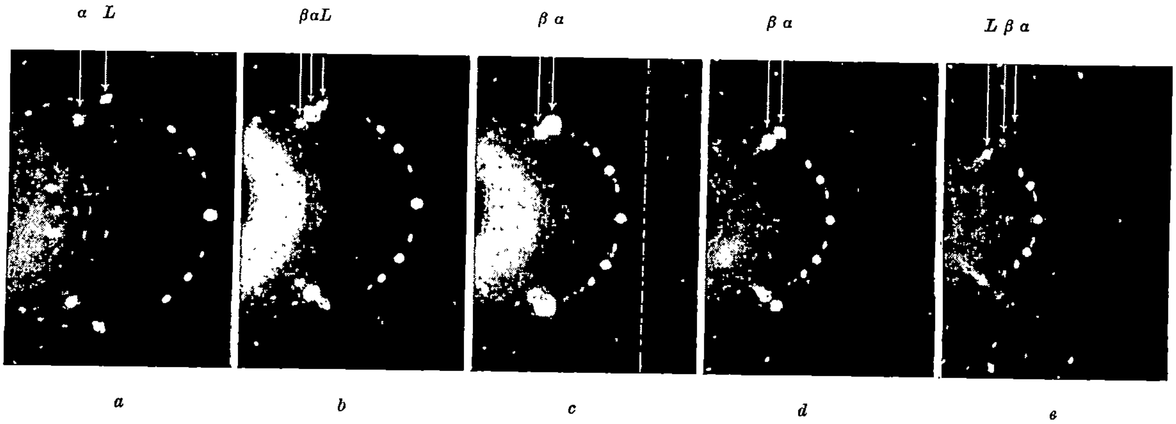

Fig. 1. Laue photographs of a crystal of potassium permanganate mounted with the *b* axis perpendicular to the X-ray beam. The angles between the *a* axis and the X-ray beam were: (*a*) 70°, (*b*) 72°, (*c*) 74°, (*d*) 76°, (*e*) 78°. The Bragg positions corresponding to the reflexions for copper K_α, copper K_β, and the Laue reflexion (*L*), from (210) are indicated

Co-crystallization of Two Tautomers: Crystal Structure of Isocytosine

DURING the course of investigations on the crystal structures of purines, pyrimidines and related compounds, we have determined the crystal structure of isocytosine and, in so doing, have uncovered an example of two different tautomeric forms of the same molecule co-crystallizing in a 1 : 1 ratio. The two tautomeric molecules of isocytosine are hydrogen-bonded to one another in a manner analogous to the pairing proposed by Watson and Crick for DNA[1].

Isocytosine crystallizes in the monoclinic space group $P2_1/n$, with unit-cell dimensions $a = 8{\cdot}745$ Å, $b = 11{\cdot}412$ Å, $c = 10{\cdot}441$ Å and $\beta = 94{\cdot}79°$. There are eight molecules in the unit cell and, accordingly, two crystallographically distinct molecules in the asymmetric unit. Complete three-dimensional intensity data for copper X-radiation were obtained from Weissenberg photographs about the *a* and *c* axes; approximately 1,750 non-zero intensities were measured. A trial structure was deduced from a sharpened three-dimensional Patterson map and was confirmed and improved by Fourier projections on to the (010) plane. Refinement was by three-dimensional least-squares methods, including anisotropic temperature factors for the heavier atoms but a single, fixed temperature factor for the hydrogen atoms. The disagreement factor *R* between observed and calculated structure factors is now 6·8 per cent. In order to obtain direct

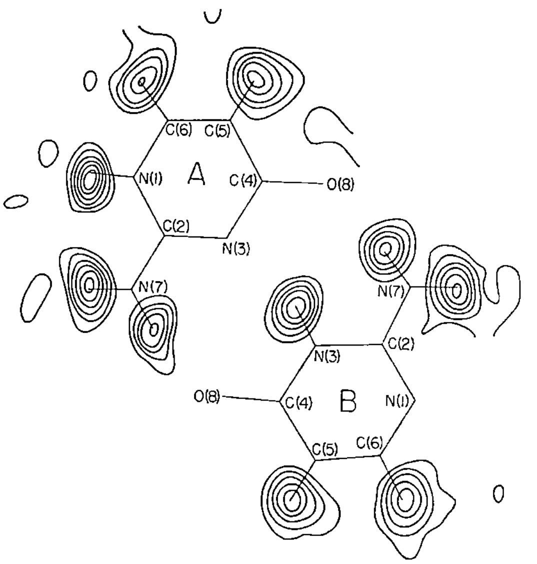

Fig. 1. The 'difference' electron density in the planes of the two tautomeric molecules of isocytosine, showing the positions of the hydrogen atoms. The coefficients used in the Fourier summations were the differences between the observed structure factors and the structure factors calculated on the basis of the carbon, nitrogen and oxygen atoms

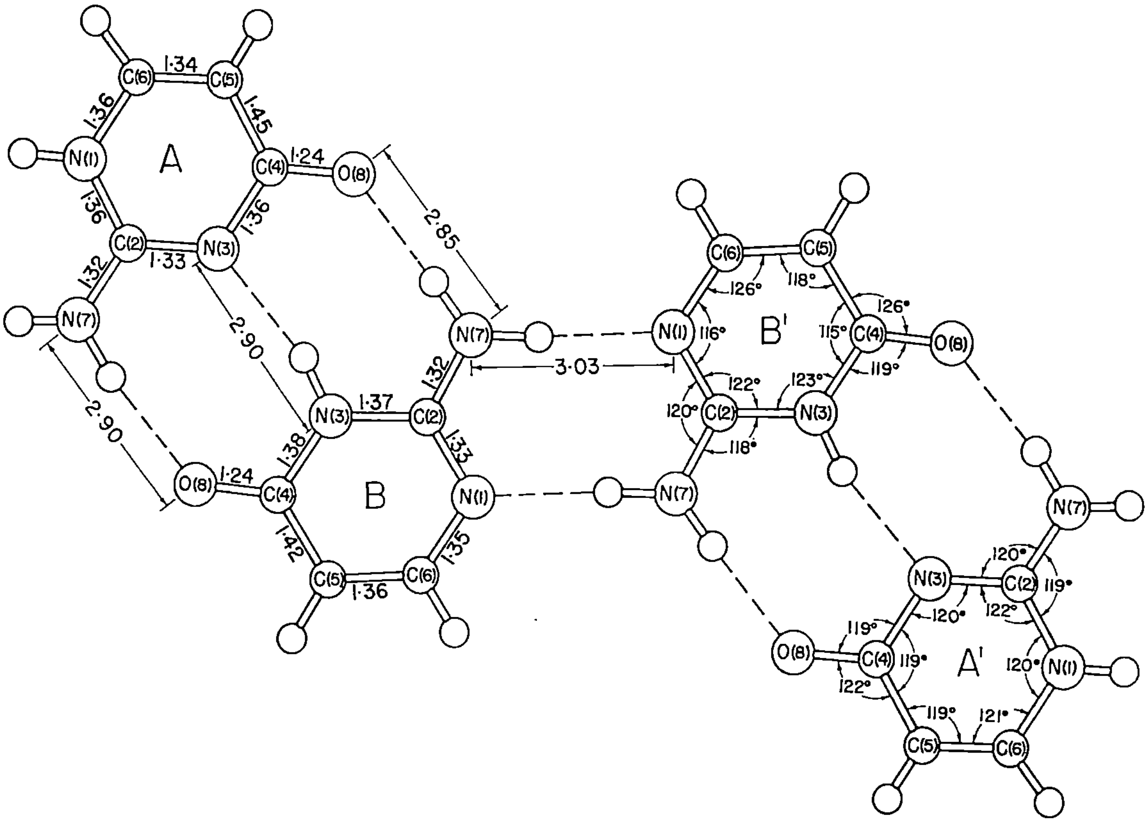

Fig. 2. Interatomic distances and angles and the hydrogen-bond arrangement in crystals of isocytosine

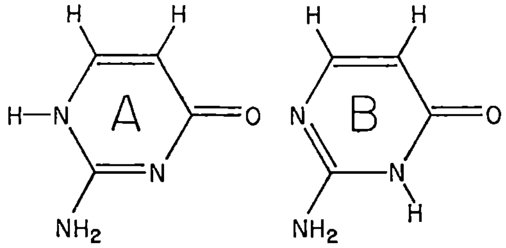

Fig. 3. The two tautomeric forms of isocytosine

evidence for the locations of the hydrogen atoms, difference Fourier syntheses were calculated in the planes of the two non-equivalent molecules, which are inclined at an angle of about 9° to one another. A composite drawing of these difference syntheses is shown in Fig. 1. The values for the bond distances and angles at the present stage of refinement are shown in Fig. 2.

The two tautomeric forms of isocytosine are shown in Fig. 3. In the crystal, a molecule of form *A* is linked to a molecule of form *B* through three hydrogen bonds, forming a hydrogen-bonded pair analogous to the purine–pyrimidine pairs proposed by Watson and Crick for the structure of DNA[1]. Each of these hydrogen-bonded pairs is, in turn, linked to another pair through two N–H · · · N hydrogen bonds arranged around a centre of symmetry, as shown in Fig. 2. Finally, the two protons at N(1) and N(7) of molecule *A* form hydrogen bonds to oxygen atoms of adjacent molecules (not shown). All the hydrogen bond lengths are typical of relatively strong bonds; with the exception of the N(1)–H · · · O and N(7)—H · · · O bonds, where the acceptor oxygen atoms are pushed apart by intermolecular van der Waals forces, the hydrogen bonds are approximately linear.

The existence of these two tautomers in the same crystal strongly suggests that they are of about equal stability, and points out the necessity of considering *p*H and the distribution of protons in formulating structures for the nucleic acids and their derivatives.

RADIATION CHEMISTRY

Synthesis of Deoxyadenosine under Simulated Primitive Earth Conditions

Recent experiments have demonstrated that many organic compounds of biological significance can be produced in a wide variety of experiments simulating primitive Earth conditions. The synthesis of the purines, adenine[1,2] and guanine[3], and the sugars, ribose[4] and deoxyribose[4,5], have been reported. It was therefore of interest to find out whether the nucleosides and nucleotides present in RNA and DNA could be synthesized under similar conditions.

Previously we found that adenosine, AMP, ADP, ATP and A4P were formed by the ultra-violet activation of adenine in the presence of ribose and ethyl metaphosphate[6]. The investigation reported here shows that deoxyadenosine in appreciable yield may be synthesized by the use of conditions which appear to be far more likely to have occurred on the primitive Earth. The dehydration reaction needed to link the purine adenine and the sugar deoxyribose can be effected by the use of hydrogen cyanide. This reaction appears to be activated by ultra-violet light. The deoxyadenosine is, however, formed even in the absence of ultra-violet light. The function of the ultra-violet light appears to enhance the yield.

100 µl. each of solutions of adenine-8-^{14}C (specific activity: 100 µc./1·7 mg), deoxyribose, $NH_4H_2PO_4$ and NaCN, were used in a series of experiments as outlined in Table 1. The concentration of the solutions used was approximately 10^{-3} M. The glass tubes containing these mixtures were frozen in liquid nitrogen, evacuated and sealed. Two sets of tubes were prepared. The first ('Vycor' glass) was exposed for 2 h to a total ultra-violet flux of approximately 10^8 ergs/cm^2 from four General Electric ultra-violet germicidal lamps, type 782*H*-10, which emit 95 per cent of their light in the mercury resonance line at 2537 Å. The 'Vycor' tubes were maintained at room temperature during this reaction. The second was allowed to stand at room temperature for 3 days.

Table 1

	Ultra-violet (per cent)	Room temperature (per cent)
(1) Adenine + deoxyribose	—	—
(2) Adenine + deoxyribose + $NH_4H_2PO_4$	5	—
(3) Adenine + deoxyribose + $NH_4H_2PO_4$ + CN^-	1	1
(4) Adenine + deoxyribose + CN^-	7	1

100 µl. of the solution from each of these tubes was spotted on a thin layer plate using 'Ecteola' cellulose as a supporting medium, together with 25 µg of non-radioactive deoxyadenosine as carrier. The thin-layer chromatogram was developed in two dimensions using water in the first dimension and butanol/acetone/acetic acid/ammonium hydroxide (35 : 25 : 15 : 25 v/v) in the other. The position of the non-radioactive carrier deoxyadenosine, which performed the function of a marker, was located by its ultra-violet absorption. Autoradiographs of the thin-layer chromatography plates on X-ray film showed coincidence of radioactivity with the location of the carrier deoxyadenosine. This area was then scraped off the thin-layer plate, eluted with N/100 ammonium hydroxide and re-chromatographed on Whatman No. 4 paper using tertiary butanol/methyl ethyl ketone/formic acid/water as solvent (40 : 30 : 15 : 15 v/v). Once again there was coincidence between the ultra-violet absorbing area on the shadowgram[7] and the radioactive spot on the autoradiograph. This coincidence, perfect in location and precise in shape, clearly established that radioactive deoxyadenosine was being synthesized from carbon-14-labelled adenine and deoxyribose. Fig. 1 illustrates one such example of coincidence. The bright spot on the shadowgram represents the carrier deoxyadenosine. The dark area on the autoradiograph shows the radioactive deoxyadenosine synthesized when a mixture of adenine, deoxyribose, and $NH_4H_2PO_4$ is exposed to ultra-violet light in the presence of CN^- The identity of the deoxyadenosine synthesized was further confirmed by ion exchange chromatography. In a control experiment where adenine and deoxyribose were subjected to the entire procedure, except treatment with CN^- and ultra-violet light or ambient heat, no detectable amount of deoxyadenosine was produced. This control experiment also established that any synthesis due to microbial action was minimal.

The results are summarized in Table 1. No deoxyadenosine was detected in the absence of CN^- or $NH_4H_2PO_4$. The maximum yield was in the experiment where CN^- alone was used with ultra-violet light. The quantitative aspects are being further investigated.

The synthesis of nucleosides and nucleotides involves a dehydration reaction. In our previous work this was effected by the use of phosphoric acid or ethyl metaphosphate in the case of adenosine, and by ethyl meta-

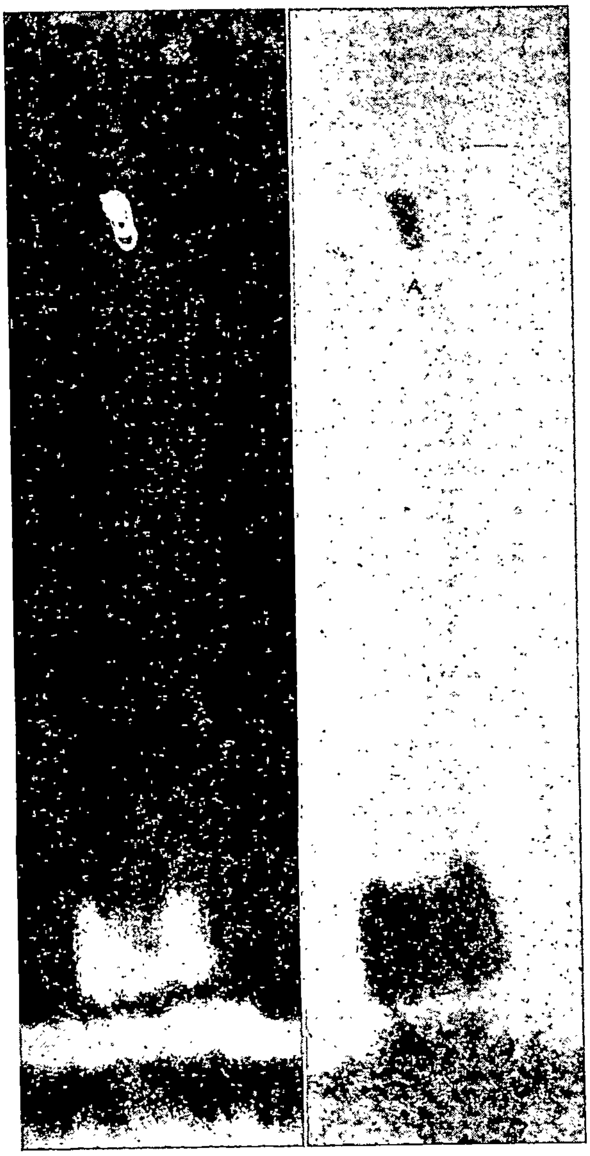

Fig. 1. Chromatogram illustrating formation of deoxyadenosine by the action of ultra-violet light on a solution of adenine and deoxyribose in the presence of CN^-. Shadowgram is on the left and the autoradiograph on the right

phosphate in the case of the nucleotides of adenosine. We now find that the same result can be obtained by the use of materials which could have occurred under primordial conditions. Hydrogen cyanide is one of the primary products of the electric discharge on mixtures of methane, ammonia and water[8], and presumably was readily available on the primitive Earth. It can react with a molecule of water to give formamide, which in turn can be hydrolysed to ammonium formate. While this report establishes the formation of deoxyadenosine by the use of CN^-, the preliminary evidence indicates that the synthesis of nucleotides and peptides can be effected by this means.

There is also evidence to indicate that cyanamide or Mg^{++} can replace CN^- to produce deoxyadenosine[10] in this reaction. The action of cyanamide may be analogous to that of di*cyclo*hexylcarbodiimide[9], which has been so extensively used by Khorana *et al.* for the synthesis of nucleotides. The presence of cyanamide, however, has not yet been detected in simulation experiments; but urea, which is formed by the addition of a molecule of water to a molecule of cyanamide, has been identified in them[8]. The chemical role of Mg^{++} in this experiment is obscure, and it is perhaps not altogether irrelevant to speculate on the relationship of this reaction to the extensive involvement of magnesium in biological processes. These results are under further investigation.

CHEMISTRY

Synthesis of Glucopeptides

THE provision of model compounds[1-5] containing amino-acids attached to sugars is of importance in evaluating the stability of the various types of carbohydrate–peptide linkages which may occur in glycopeptides. Hitherto, investigations[1,2,6-8] with hexosamines (usually D-glucosamine) have been confined largely to the synthesis of compounds (the so-called glucopeptides) involving single amino-acid residues, and instances of the condensation of hexosamines with dipeptides and higher peptides are rare. Bertho and Maier[9], for example, synthesized *N*-(dialanyl)-D-glucosamine by treatment of 1,3,4,6-tetra-*O*-acetyl-*N*-alanyl-D-glucosamine with 2-azidopropionylchloride followed by reduction of the azide group to an amine. Such syntheses involve several stages and are difficult to accomplish.

The selectivity of amide bond formation in the presence of di*cyclo*hexylcarbodiimide[8] provides a simple method for direct, selective *N*-acylation of unprotected amino-sugars. The exclusive formation of *N*-substituted derivatives in aqueous pyridine has been attributed[8] to the specific action of di*cyclo*hexylcarbodiimide and to the instability of *O*-acyl derivatives under these conditions. This reagent has been used recently in the synthesis[10] of several *N*-aminoacyl derivatives of D-glucosamine and the amino-acid moiety extended in length to di- and tri-peptides. Thus, reaction of *N*-glycyl-D-glucosamine with *N*-carbobenzoxyglycine afforded *N*-(*N*-carbobenzoxydiglycyl)-D-glucosamine from which the protecting group was later removed by catalytic hydrogenation. We have used the alternative approach in which D-glucosamine has been condensed directly with suitably protected dipeptides by the following general procedure.

To a cooled (0°) and stirred solution of D-glucosamine hydrochloride (1·2 g) in water (5 ml.) was added 2 N sodium hydroxide solution (2·8 ml.) and thereafter a solution of *N*-carbobenzoxyglycylglycine (1·5 g) in pyridine (25 ml.). To this was added a solution of di*cyclo*hexylcarbodiimide (1·75 g) in pyridine (25 ml.) and stirring was continued for 24 h at room temperature. The precipitated di*cyclo*hexylurea was filtered off and unreacted di*cyclo*hexylcarbodiimide was extracted with ether (2 × 50 ml.). The aqueous layer was concentrated under reduced pressure to an amorphous residue which was crystallized from methanol to give pure *N*-(*N*-

carbobenzoxydiglycyl)-D-glucosamine (0·74 g), m.p. 185°–187° (decomp.), $[\alpha]_{Hg}^{20}$ + 77° (equil., *c*, 0·37 in pyridine) (lit.[10] m.p. 190°–192° (decomp.), $[\alpha]_{D}^{20}$ + 56·7°→ + 58·4°) (found: C, 50·7; H, 5·7; N, 9·6. $C_{18}H_{25}N_3O_9$ requires C, 50·6; H, 5·9; N, 9·8 per cent). The product gave a positive response on paper chromatograms with aniline hydrogen phthalate[11] and potassium iodide-starch[12] sprays but no response with ninhydrin[13].

The foregoing procedure has been used in the synthesis of *N*-(*N*-phthalyldiglycyl)-D-glucosamine, m.p. 220°–222° (decomp.) (from aqueous ethanol), $[\alpha]_{Hg}^{21}$ + 71° (*c*, 0·93 in pyridine) (found: C, 51·2; H, 5·2; N, 10·0. $C_{18}H_{21}N_3O_9$ requires C, 51·0; H, 5·0; N, 10·0 per cent). The products resulting from a similar condensation of D-glucosamine with *N*-phthalylglycyl-DL-leucine are diastereoisomers. Fractional recrystallization from methanol gave a pure isomer, m.p. 238°–242° (decomp.), $[\alpha]_{Hg}^{23}$ + 138° (*c*, 0·02 in pyridine) (found: C, 54·9; H, 6·3; N, 9·0. $C_{22}H_{29}N_3O_9$ requires C, 55·1; H, 6·1; N, 8·8 per cent). Attempts to separate the diastereoisomers following condensation of D-glucosamine with *N*-phthalylglycyl-DL-alanine were unsuccessful.

The commercial availability of a number of di- and tri-peptides renders this procedure of potential, general application in the synthesis of glucopeptides incorporating these units. The stability of the amide linkages in the foregoing compounds to acidic hydrolysis will be discussed in a subsequent publication.

Optical Investigations of Film Formation and Removal on Gold Anodes in Acidic Oxalate Solutions

RECENT investigations of the oxidation of oxalate ions in acidic solutions using gold anodes have provided electrochemical evidence for the formation of a film on this anode during steady-state electrolysis at potentials well below that for Au_2O_3 formation, 1·36 V normal hydrogen electrode[1]. The determination of the nature of the film on gold at potentials below 1·36 V using electrochemical techniques has introduced uncertainties as to whether the film is a 'three dimensional' oxide film or a 'two dimensional' chemisorbed oxygen film. Some investigators[2–5] using charging curves as their basis conclude that the formation of an oxide occurs only above 1·36 V, the formation of a chemisorbed oxygen film being the process occurring below this potential. The formation of this chemisorbed oxygen film begins at potentials as low as 1·15 V (ref. 6). Other work, however, also based on electrochemical evidence, indicates that the formation of an oxide film does occur below 1·36 V (ref. 7).

This communication describes work that is directed at resolving these uncertainties and supplementing the evidence for concurrent film formation with oxalate oxidation[1] by applying an optical technique, ellipsometry[8]. This technique enables one to study the formation and decay of films on anodically polarized metal surfaces. With ellipsometry it is possible to determine in a more direct way the nature and extent of formation of the film found on gold below 1·36 V than by the purely electrochemical methods used in the previous studies described here.

All observations were made in a cell similar to that previously described[9] with the exception that no attempt was made to exclude air. The solutions were prepared directly from reagent grade sodium oxalate and c.p. sulphuric acid. All experiments were performed at room temperature. The gold electrodes (both foil and rod were used) were degreased in spectroscopic grade acetone and methanol, then flamed in a burner briefly before use. They were then placed in the cell and the potential of the gold brought to selected potentials by means of a potentiostat. The gold surface was either cleaned by evolving hydrogen vigorously or by reduction at 0·0 V. Either treatment was equally satisfactory. Ellipsometer readings were then made at various anodic potentials in two different concentrations of oxalate—4 g/l. and 20 g/l. in 1 M sulphuric acid or in a 1 M sulphuric acid solution containing no oxalate.

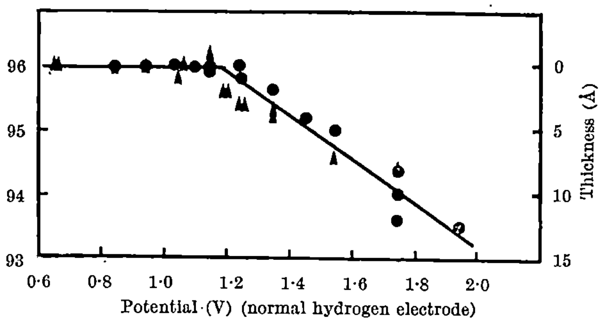

Fig. 1. ▲, 1 M sulphuric acid; ●, 1 M sulphuric acid and 4 g/l. $Na_2C_2O_4$

A film formed in the 1 M sulphuric acid solution with and without 4 g/l. $Na_2C_2O_4$ as indicated by the observation that relative phase retardation, Δ, varied linearly with the anode potential above 1·1 V (Fig. 1). The relative amplitude reduction (tan Ψ) was essentially constant in this potential region. The fact that Δ decreased while tan Ψ was essentially constant with increasing potential (increasing film thickness) indicates that a film having a refractive index greater than that of the solution (1·33) was forming[9]. This would strongly indicate that an oxide of gold, which would be expected to have a refractive index higher than the solution, would be formed rather than an oxygen film, the optical constants of solid oxygen films on gold being 1·25 (ref. 8). For such a film, calculations using the equations connecting Δ and tan Ψ (ref. 8) show that, if a film is thin (< 30 Å), a reasonable estimate of the film's thickness can be made without knowing the exact value of its refractive index; namely, a 2° decrease in Δ corresponds roughly to a 10 Å increase in film thickness. This is the basis for the estimated thickness values shown in Fig. 1. This figure also shows that the growth of a film on gold (above 1·1 V) occurs in a continuous manner, and not at discrete potentials, in general agreement with the type of mechanism proposed by Laitinen and Chao[10].

The time-interval between successive values of potential was several minutes. If, however, the potential was kept constant, the film continued to grow very slowly with a logarithmic dependence on time. Thus after 1,000 min at 1·74 V the film thickness was observed to be $\sim$ 20 Å. The fact that optical changes occurred while the potential was constant indicates that these changes were due to film growth rather than to changes in optical parameters occurring in the solution at the metal-solution interface produced by a change in the potential of the metal surface.

Once the film had begun to form in the solution containing 4 g/l. of $Na_2C_2O_4$ the rate of oxalate oxidation decreased. Lowering the potential from 1·74 V to 1·24 V resulted in a fairly slow first-order decay of the film. The same was true on open circuit. The film was easily reduced by setting the potential to values below 1·1 V with the potentiostat. Essentially the same results were obtained in 1 M sulphuric acid alone, but the film was not readily removed by the acid either on lowering the potential to about 1·2 V or on open circuit. With a sodium oxalate concentration of 20 g/l. the rate of reaction of oxalate with the film was so rapid that no film formation was observed up to 1·94 V, within the limit of detection of the ellipsometer.

Infra-red Spectra of Aqueous Solutions by the Attenuated Total Reflectance Technique

IT has recently been suggested[1,2] that the attenuated total reflectance (ATR) technique is superior to the conventional transmission technique for obtaining the infra-red spectra of aqueous solutions, with the implication that the intense absorption bands of liquid water appear to be relatively weaker in ATR spectra. We have examined the spectra of a number of aqueous solutions by both methods and have in no case found the ATR spectra to be superior.

It is generally accepted that in the ATR system the radiation beam interacts only with the surface layer of the sample although the exact depth of penetration is a function of the complex refractive index, angle of incidence and wave-length. Parker[2] reports an apparent transmission of about 50 per cent for pure water by ATR methods at the 6·3 μm absorption peak. The transmission spectra of Ackermann[3] show that a path length of the order of 5 μm does in fact allow 50 per cent transmission at this wave-length.

It seems, therefore, that the ATR technique possesses no inherent advantage over the transmission technique for the examination of aqueous solutions. For concentrated solutions in regions of intense water absorption, the ATR technique circumvents the practical difficulties of filling and cleaning very short path length transmission cells. Where adsorption on the ATR prism surface allows higher solute concentrations to be established, the multi-reflexion ATR technique could probably be used with advantage, although the spectrum of the adsorbed material will not necessarily be the same as that of the material in true solution. These observations in no way detract from the value of the ATR technique for obtaining the spectra of intractable water containing samples which would be difficult or impossible to examine by transmission methods.

We thank the Research and Industrial Instruments Co., London, for assistance in the examination of ATR spectra.

Electronic Structures of Kryptates and Xenates

THE recent preparation of kryptates[1] and xenates[2] by Grosse *et al.* opens a new chapter in rare-gas chemistry. Up to now the compounds that have been made have presented no new problems in chemical bonding; no problems that were not already present in the chemistry of iodine and tellurium, etc. Most of the fluorine and oxygen compounds of xenon that have been prepared have isoelectronic analogues in the chemistry of iodine, for example, $XeF_6(IF_6^-)$, $XeF_4(IF_4^-)$, $XeF_2(ICl_2^-)$, XeO_3 (IO_3^-) and $XeO_6^{4-}(IO_6^{5-})$. Xenates based on XeO_6^{6-} are therefore a new type of compound. Similarly krypton forms $KrO_3(BrO_3^-)$, but kryptates (KrO_4^{--}, KrO_6^{6-}?) have no isoelectronic counterparts.

Rubidium and cæsium follow krypton and xenon in the periodic sequence, and in these elements the circum-rare-gas electron is in a 5*s* or a 6*s* orbital. While these electrons are loosely bound (Rb, 4·2 eV; Cs, 3·9 eV) it seems reasonable to suppose that such orbitals may play some part in bonding in rare-gas compounds. Calculations by Craig and Zauli[3] have shown that many ligands and especially electron attracting ligands can, by polarizing the valency-shell electrons of a non-transitional element, confer on the diffuse and loosely bound *d* orbitals an enhanced bonding potential. The empty 5*s* and 6*s* orbitals that surround krypton and xenon should be similarly affected by ligands such as oxygen and fluorine. These ligands will also enable the krypton 4*d* and the xenon 5*d* and 4*f* orbitals to play some part in bonding. Oxygen's 2*p* orbital is less tightly bound than fluorine's. It is, therefore, nearer in energy to the 5*s* (Kr) or 6*s* (Xe) orbitals and, being more diffuse than the fluorine orbital, it will overlap better with the loosely bound rare-gas orbitals. These two effects combine[4] in making the outer orbitals of krypton and xenon more important in bonding to oxygen than to fluorine.

In the tetrahedral oxy-anions, germanate, arsenate, etc., the four oxygen ligands may be thought of as each having one *p* orbital directed towards the central atom. These four *p* orbitals will belong to irreducible representations a_1 and t_2 of the point group T_d. The a_1 oxygen orbital will, therefore, interact with the valency 4*s* orbital and the empty 5*s* orbital in these anions. Ignoring the possible effect of the 5*s* orbitals it has been argued[5] that since the 4*s* orbital becomes more tightly bound in going from germanium to bromine the efficiency of a_1-type bonding will decrease. In BrO_4^- only the bromine 4*p* orbitals contribute effectively to the bromine–oxygen bonds. Thus BrO_3^- is stable, but, in the absence of other effects, BrO_4^- should be unknown. (In isoelectronic ClO_4^-, 3*d* orbitals form π-bonds with oxygen enhancing the anion's stability. Because of the presence of a spherical node $4d$ orbitals do not π-bond well.)

The effect, of including the $5s$ orbital, on bonding in these tetrahedral oxygen complexes is to change the 'antibonding' molecular orbital associated with the a_1 oxygen orbital into a 'bonding' orbital for krypton and possibly for bromine as well. In these elements the $4s$ orbital is very tightly bound (Br, 23·8 eV; Kr, 27·5 eV)[6] and so will play little part in bonding with the oxygen orbitals. Thus $5s$–a_1 is the more important interaction and a molecular orbital, bonding relative to the oxygen $2p$ atomic orbital, is generated.

When electrons are put into this orbital (a_1) framework the first two will contribute little or nothing to the bonding and KrO$_4$, like BrO$_4^-$, should be unknown. But the next two electrons can enter a bonding molecular orbital so that KrO$_4^{--}$ should be stable and perhaps BrO$_4^{---}$ as well. A further possibility is RbO$_4^-$, but the rubidium $4p$ orbitals are quite tightly bound (20·7 eV) and t_2 bonding to oxygen might be too weak for the anion to exist.

Octahedral co-ordination of the third row elements is rare. While this may be due to the radius–ratio effect[7], it may also be ascribed to the absence, if $4s$, $4p$, $4d_{z^2}$ and $4d_{x^2-y^2}$ are all used for σ bonding, of enough suitable orbitals with which oxygen might form π bonds. In the fourth-row elements a small effective nuclear charge (~ 3) is sufficient to bring the radial maximum of $4f$ hydrogen like orbitals[8] into the bonding region. Elements such as tin, iodine and xenon can enjoy octahedral co-ordination by oxygen and also the formation of π bonds. Kryptates are, therefore, expected to be KrO$_4^{--}$ but xenates XeO$_6^{6-}$. Cæsates based on CsO$_6^{5-}$ might also be formed, and since the $5p$ orbitals of cæsium are less tightly bound than the $4p$ orbital of rubidium, they might be more stable than rubidiates.

As with krypton, xenon's outer $6s$ orbital may well interact strongly with the 'antibonding' a_{1g} molecular orbital derived from $5s$–a_{1g} (oxygen) interaction (weak with xenon because the $5s$ orbital is tightly bound, 23·4 eV), making it bonding relative to the oxygen $2p$ atomic orbital. In per-xenates (XeO$_6^{4-}$) this bonding pair is absent but π bonding strengthens the bonding in both anions. Tetrahedral co-ordination of tellurium and iodine by oxygen is also known (TeO$_4^{--}$, IO$_4^-$). In these anions π bonding probably strengthens weak σ bonds as in ClO$_4^-$. Xenon might, therefore, form isoelectronic XeO$_4$ and xenates based on XeO$_4^{--}$ may also be formed.

The models for xenates and kryptates considered here have been based on regular octahedra and tetrahedra. This is reasonable only if the $4s$ (Kr) and $5s$ (Xe) orbitals are so tightly bound that they have no stereochemical effect. Since the formation of these anions depends on the s orbitals being tightly bound this does not seem too extreme an assumption.

Note added in proof. Since this communication was submitted the preparation of XeO$_4$ has been reported[9].

Free Radicals from Selenium and Sulphur Antioxidants

Research on the biochemical function of trace selenium in animal nutrition indicates it probably functions in lipid antioxidant and free radical acceptor reactions. Selenoprotein fractions from selenate-fed animals have up to 500 times the antioxidant activity of vitamin E (ref. 1). Selenoamino-acids were very effective in reducing free-radical damage to enzymes and amino-acids when aqueous solutions were exposed to ionizing radiation[2]. Woodbridge[3] found organic selenium compounds to be powerful antioxidant agents. These unusual properties of selenium compounds in reacting with free radicals suggested that an electron paramagnetic resonance investigation of selenium amino-acids and antioxidants and their sulphur analogues would be of interest.

Sulphides and selenides were irradiated at 2537 Å at liquid nitrogen temperature in quartz tubes for periods up to several hours. Spectra were immediately taken on an X-band electron paramagnetic resonance spectrometer with the samples maintained at liquid nitrogen temperature. The electron paramagnetic resonance spectra fall into four categories characteristic of the radicals formed by irradiation. These are: alkyl radicals, benzyl-type radicals, sulphur radicals and selenium radicals.

Alkyl radical, —CH$_2\dot{\text{C}}$HCH$_2$—, spectra were obtained from di-n-dodecyl and di-n-octadecyl sulphide and selenide. These consist of eight-line spectra centred at $g = 2{\cdot}002$.

Dibenzyl sulphide, dibenzyl selenide and dibenzyl diselenide each gave a simple spectrum centred at $g = 2$ and 30 gauss wide. Since no sulphur or selenium spectra are observed we interpret the results as the spectrum of a benzyl radical, —X—ĊH—. A similar spectrum from selenocystine suggests that it may form the radical HOOCCH(NH$_2$)ĊHSe - - -.

Electron paramagnetic resonance spectra of the sulphur radicals gave a derivative pattern with seven points of inflexion indicating three unequal g values (Table 1).

Table 1. g Values of Sulphur Radicals

Irradiated compound	g_1	g_2	g_3
Cystine	2·001	2·022	2·062
Cysteine	2·000	2·025	2·052
Dibenzyl disulphide	1·995	2·024	2·053
Di-n-butyl disulphide	1·998	2·025	2·058
Di-n-dodecyl sulphide	1·998	2·022	2·057

Spectra that we assign to selenium radicals have derivative shapes characteristic of axially symmetric g factors. The g factors are designated as $g_{\parallel}$ and $g_{\perp}$ for directions parallel and perpendicular to the symmetry axis. As a check on this interpretation, an average g value was calculated, $\langle g \rangle_{\text{calc}} = 1/3\ g_{\parallel} + 2/3\ g_{\perp}$, and compared with the experimental $\langle g \rangle$ value. The g values for selenium are given in Table 2. The agreement between $\langle g \rangle_{\text{calc}}$ and $\langle g \rangle_{\text{exp}}$ is within experimental error. The g values for selenium are higher than those for sulphur, as would be expected since the g-value shifts depend on the degree of spin-orbit coupling which increases rapidly with atomic number.

Table 2. g Values for Selenium Radicals

Substance	Radical	$g_{\parallel}$	$g_{\perp}$	$\langle g \rangle$	$\langle g \rangle_{\text{calc}}$
Di-n-octadecyl selenide	CH$_3$(CH$_2$)$_{17}$Se·	2·115	2·083	2·095	2·094
Di-n-dodecyl selenide	CH$_3$(CH$_2$)$_{11}$Se·	2·122	2·088	2·098	2·099
Benzyl selenomercaptan	–CH$_2$Se·	2·124	2·091	2·099	2·102

General results of ultra-violet irradiation and electron paramagnetic resonance examination of these sulphur and selenium antioxidants are: (1) in disulphide compounds the disulphide bonds always rupture; (2) in diselenide compounds the diselenide bond does not rupture; but a radical may be located elsewhere, usually on a methylene carbon; (3) in thiol and —SeH compounds the proton on sulphur or selenium is labile; (4) in di-aliphatic sulphides and selenides the C—S or C—Se bond usually ruptures; (5) in dibenzyl sulphide and selenide compounds the C—S or C—Se bonds do not rupture; instead, a proton is removed from the methylene group.

BIOPHYSICS

Light-induced Absorption-change Transients in Some Blue-green Algae

As reported recently[1,2], in aged chloroplasts of spinach the decay of the light-induced absorption decrease at 430 mμ becomes biphasic when the system is coupled with ascorbic acid and an appropriate amount of the redox dye phenazine methosulphate. It was further found that the slowly decaying portion becomes saturated at a lower actinic intensity and the rapidly decaying portion starts to appear only when the actinic intensity exceeds the threshold-level. The biphasic decay was attributed to the re-reduction of two separate photo-oxidized species, possibly the chlorophyll complex *P*700 and cytochrome *f*.

In this communication is reported the finding of a decrease in light absorption at 430 mμ with a similar complex decay kinetics in whole cells of several blue-green algae. *Plectonema boryanum, Phormidium luridum, Glœocapsa alpicola*, and *Anacystis nidulans* have been examined, and all show more or less the same characteristics. Fig. 1 shows a typical transient absorption change at 430 mμ obtained from *Plectonema*, which gave the largest signal among the species studied. The total optical density change shown in Fig. 1 was about 0·006. Broad-band red (645–745 mμ) flashes of 20-μsec duration spaced at 2-sec intervals were used for excitation. The signal shown in Fig. 1 was obtained by integration of 30 flashing cycles through the *CAT*-computer. Detailed experimental procedures have been described previously[3].

On the average, the decay constants of the rapid and slow portions are 10 and 300 ± 50 msec, respectively. In most fresh blue-green algal cells, the ratio of the two signal heights is nearly unity. The extent of the rapidly decaying portion usually decreases on storage. *Plectonema* stored in the dark at 0° C for one month still retained 50 per cent of the activity without change in the signal ration. Preliminary examination indicates that the light-minus-dark difference spectrum of the rapidly decaying portion resembles that of an oxidized cytochrome while the difference spectrum of the slowly decaying portion agrees closely with that of the oxidized *P*700[4-6].

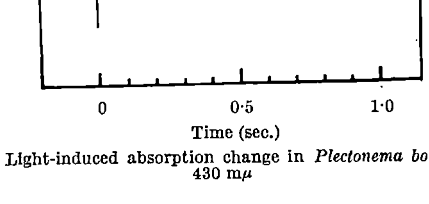

Fig. 1. Light-induced absorption change in *Plectonema boryanum* at 430 mμ

Since blue-green algae are relatively heat-resistant, the transient absorption changes are little affected when the cells are heated for 5 min at temperatures up to 50° C. When heated to higher temperatures, the rapidly decaying portion is affected and begins to disappear, while the slowly decaying portion remains intact. When heated above 60° C, both signals are eliminated.

The actinic-intensity dependence of the composite signal in blue-green algae is similar to that of aged chloroplasts[1,2]. At the threshold intensity of approximately 2×10^{14} quanta cm^{-2} per flash, the rapidly decaying signal starts to appear. At lower actinic intensity, only the slowly decaying portion can be observed.

Cells incubated with 3×10^{-5} M 3(3,4-dichlorophenyl)-1,1-dimethyl urea yielded practically the same composite signal. Sonicated cells, from which phycocyanin was liberated, yielded transients of smaller signal height, but with similar complex decay kinetics. The 430 mμ transient presented here is associated with the long-wave-length reaction centre. This is shown by the fact that 10 mμ-wide flashes at 680 or 690 mμ can also induce the complex transient signal but it has smaller overall height. Preliminary examination with actinic flashes at 620 or 590 mμ, at which phycocyanin absorbs, showed that the accessory pigment has a quite different behaviour of sensitization. Detailed investigations of the action spectrum are in progress and will be reported elsewhere.

BIOCHEMISTRY

Direct Extraction of Actin in the Fibrous Form from Fish Muscle

Water extraction of an acetone-dried muscle powder preparation of rabbit[1] is one of the standard methods of producing a solution of globular or *G*-actin. Such a solution possesses no birefringence of flow and has a low specific viscosity[2]. On making this solution 0·1 M with respect to potassium chloride, 0·001 M with respect to Mg^{++} and allowing to stand, a marked birefringence of flow develops and the solution has a considerably increased specific viscosity. These changes have been classically considered to be a result of the polymerization of the *G*-actin, as extracted, to the fibrous or *F*-form.

During the course of investigations of the muscle proteins of various animals it was observed that actin can apparently be extracted directly from fish acetone-dried muscle powders in the *F*-form. Acetone-dried muscle powders were prepared from salt- and fresh-water fish of various species by the method of Barany, Barany and Guba[1]. The fish were killed by decapitation or a blow on the head, the dorsal muscle dissected out as quickly as possible and minced twice through an ordinary kitchen mincer. The muscle was then treated twice with 10 vol. 0·4 per cent sodium bicarbonate, washed with 15 vol. of water and dried thoroughly with pre-cooled acetone. The powder was allowed to dry in the air overnight at room temperature and stored at 4° C. The muscle powder must be prepared very carefully, particularly during the stage of acetone drying. For example, in the case of chub, which appears to have an unusually loose texture of the myonemes, unless great care is taken to express water from the muscle granules during the final acetone drying procedure a preparation results which on extraction gives actin in the *G*-form.

Actin was obtained from the acetone-dried muscle powder by treatment with 10 vol. of boiled out de-ionized water for 1 h at room temperature without stirring. Such a water extract of fish muscle powder possesses a marked birefringence of flow and a relatively high specific viscosity, suggesting that a proportion of the extracted actin is in the fibrous form. *F*-actin extracted directly in this manner has been termed *Fn*-actin to distinguish it from *F*-actin prepared by the normal polymerization process. Table 1 shows the results obtained from various species of fish together with the results of a rabbit muscle extraction for comparison.

Table 1. COMPARISON OF ACTIN EXTRACTED FROM RABBIT AND FISH ACETONE-DRIED MUSCLE POWDER

	Protein conc.	Before adding salt		After adding salt	
		Birefringence	η spec.	Birefringence	η spec.
Rabbit	2·7	0	0·03	+	0·31
Fresh-water fish					
Trout	2·95	+	0·45	+	0·65
Chub	8·0	+	0·47	+	0·74
Barbel	7·1	+	0·28	+	0·79
Dace	—	+	—	+	—
Perch	4·4	+	0·29	+	0·54
Salt-water fish					
Cod	15·0	+	—	+	—
Pollack	2·5	+	0·23	+	0·93
Plaice	3·0	+	0·36	+	0·80
Conger eel	4·2	+	0·15	+	0·83

The fact that the fish actin is not extracted completely in the fully polymerized form is suggested by the increase in viscosity on the addition of salt.

It has also been noted that the ability to extract *Fn*-actin from a muscle powder decreases with time of storage at 4° C as may be seen from Table 2. After seven days the proportion of actin extracted directly in the *F*-form is considerably decreased, although the fact that the actin is still polymerizable is demonstrated by the viscosity increase on adding salt. Thus to obtain a good *Fn*-actin extraction it is necessary to use freshly prepared muscle powder.

Table 2. AGEING OF FISH ACETONE-DRIED MUSCLE POWDER AT 4° C

Age (days)	Viscosity (η spec.)	
	Before adding salt	After adding salt
1	0·44	0·61
7	0·23	0·52
30	0·18	0·22

The observation that actin may be extracted directly from fish muscle in the *F*-form appears to reinforce the argument that actin is present in the intact myofibril in the fibrous form, as suggested by Barany, Barany and Guba's[1] experiments on the preparation of actin from muscle without prior extraction of myosin, and Martinosi, Gouvea and Gergely[3], who came to the same conclusion as a result of isotope investigations. Further support to this theory comes from Tsuboi and Hayashi's[4] recent demonstration that acetone-dried muscle powder itself contains no ATP (the bound nucleotide component of *G*-actin) but that it is synthesized from the ADP present during the water extraction procedure, and they further suggest that there must be complicating reactions in the generally accepted preparative procedure for actin.

If it is accepted that actin is present in acetone-dried muscle powder in the *F*-form, as indicated by the absence of ATP, then it would follow that one of the reactions proceeding during water extraction is that of depolymerization. The fact that actin may be extracted in the partially polymerized form from fish muscle would suggest that the depolymerization reaction is possibly under the control of some system which is absent or inhibited in the case of fish. The figures in Table 2 indicate that the ability of a muscle powder to produce *Fn*-actin decreases at a faster rate than the 'activity' (as measured by ability to polymerize) of the *G*-actin. This could be explained by the presence of a labile polymerizing–depolymerizing system in muscle, the balance of which varies in animals from different species or may be altered by the technique of preparation of the muscle powder or its subsequent treatment. In order to substantiate this hypothesis, a close examination must be made of the reactions occurring during the process of extraction of actin from acetone-dried muscle powder together with a comparison of this process in muscle powder extraction systems from various species. This work is in progress and the results will be published elsewhere.

Conjugated Oxosteroids in Human Urine

IT has long been known that oxosteroids are excreted in human urine in conjugated form chiefly as sulphates or glucuronidates. In order to test the hypothesis that the choice of either sulphate or glucuronidate in different individuals may be wholly or partially determined by genetical factors it was necessary to devise a simple and rapid method for the separation and identification of these two groups of conjugates. In the course of these experiments it was found that a third type of conjugate, oxosteroid phosphate, also occurred in human urine.

Methods for the high-voltage electrophoretic separation of steroid conjugates have been described[1,2]. It was found, however, that the conjugates could be very conveniently separated at lower voltages by the following procedure.

The K or Na salts of dehydroepiandrosterone sulphate, androsterone sulphate[3], and androsterone glucuronidate[4], as well as dehydroepiandrosterone phosphoric acid and its sodium salt[5], were prepared. These substances were assayed without previous hydrolysis by a modified Zimmermann reaction. The steroid moieties were 94 and 91 per cent respectively of the theoretical values for dehydroepiandrosterone sulphate and androsterone sulphate, 99 per cent for the dehydroepiandrosterone phosphoric acid and 95 per cent for the androsterone glucuronidate. The glucuronic acid moiety was 93 per cent of theory. The pyridinium salts of androsterone and dehydroepiandrosterone potassium sulphates were also prepared[6]. The steroid content was 100 and 95 per cent respectively of theory.

Electrophoresis was carried out in a horizontal glass tank using Whatman No. 3 *MM* paper and veronal buffer *p*H 8·6–8·9. The paper was 52 cm in length and separate lanes were made by cutting out 2-mm strips. Androsterone potassium sulphate and androsterone glucuronidate were applied in the first lane, dehydroepiandrosterone potassium sulphate and androsterone glucuronidate in the second lane, and a mixture of the three conjugates in the third lane. Electrophoresis was carried out at 320 V for 4 h at room temperature and the

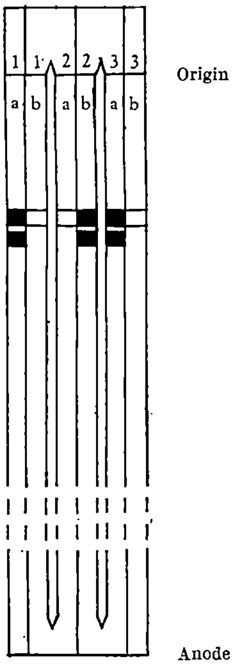

Fig. 1. Copy of electrophoretogram showing separation of: (1) ASO_3K from A gluc.; (2) $DHASO_3K$ from A gluc.; (3) ASO_3K and $DHASO_3K$ from A gluc. Strips *a*, developed with Zimmermann reagent, strips *b*, with naphthoresorcinol. Electrophoresis 4 h, veronal buffer *p*H 8·6, 320 V, Whatman No. 3 *MM* paper

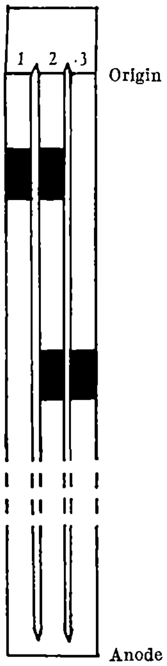

Fig. 2. Copy of chromatogram showing separation of $DHASO_3K$ from $DHAPO_3H_2$ in Schubert's system *E*: (1) $DHASO_3K$; (2) mixture of (1) and (3); (3) $DHAPO_3H_2$

paper then dried at 65°–70° C for 30 min. 1 cm of each of the 2-cm strips was developed for glucuronidate by dipping into a modified naphthoresorcinol reagent and heating to 120° C for 10 min. The remaining strips were developed with the Zimmermann reagents.

Fig. 1 shows that the steroid sulphates separate well from androsterone glucuronidate but not from each other, neither do their pyridinium sulphates separate from each other.

Dehydroepiandrosterone phosphate was also separated effectively from dehydroepiandrosterone sulphate, the latter having the greater mobility. For the location of the phosphate, published methods[7,8] were modified as follows: the paper was dried at 65° C for 30 min, cooled to room temperature, dipped into molybdate reagent and the excess solution allowed to drain off before reheating for 7 min at 85°–90° C. The paper was cooled, drawn through the reducing reagent and dried in a current of air. After a few minutes a light blue colour developed.

Effective separations were also achieved for sodium pregnandiol glucuronidate and glucuronic acid from each other and from dehydroepiandrosterone potassium sulphate, and for glucuronic acid from androsterone-glucuronidate.

Urinary 17-oxosteroid sulphates were extracted as pyridinium salts[6]. Total pyridinium salt in the extracts ranged from 2·2 mg to 5·5 mg/g creatinine in the urine. Electrophoresis of 80 μg of these mixtures showed 3 well-defined Zimmermann reacting zones. The zone with least mobility contained steroid phosphate.

A chromatographic separation of dehydroepiandrosterone phosphate from the potassium salt of dehydroepiandrosterone sulphate was also effected in Schubert's system *E* (ref. 9).

The mobility of dehydroepiandrosterone phosphate was 3 times that of the potassium salt of dehydroepiandrosterone sulphate as shown in Fig. 2.

Polymorphism of Zinc-α_2-Human Glycoprotein

Genetically determined variants of a large number of proteins, including many blood proteins, have been discovered, especially since the introduction by Smithies[1] of the gel-electrophoresis technique. α_1-Acid glycoprotein, one of the low-molecular-weight normal human plasma proteins, proved to be polymorphic near its isoelectric point. Pooled α_1-acid glycoprotein revealed seven and, after enzymatic removal of its sialic acid, two bands[2]. The human β_2-mucoid the molecular weight of which is similar to that of the mentioned α_1-globulin showed a very similar resolution[3]. We report in this communication the polymorphism of a low-molecular-weight α_2-glycoprotein, zinc-α_2-glycoprotein[4].

Zinc-α_2-glycoprotein was isolated as described earlier[4] from large pools of outdated normal plasma collected in the New England area. This glycoprotein appeared homogeneous on ultracentrifugation, electrophoresis, chromatography, and NH_2-terminal amino-acid analysis. Its extinction coefficient was again found to be 18 (ref. 4). Horizontal starch gel electrophoresis[1] was carried out in the cold over the *p*H range of 2·7–8·6.

At *p*H 8·6 in borate or *tris*-EDTA-borate buffer zinc-α_2-glycoprotein exhibited a single band. Near *p*H 6 in cacodylate, citrate or phosphate, one main band was observed. Between *p*H 5·5 and 4·7 this plasma globulin revealed eight zones, whereas twelve bands were found in the *p*H range 4·0–3·5. The higher resolution noted over the latter *p*H region is probably related to the partial denaturation of this protein, which is known to occur at *p*H values acid to its isoelectric point[4]. At *p*H 3·0 in phosphate buffer, zinc-α_2-glycoprotein showed

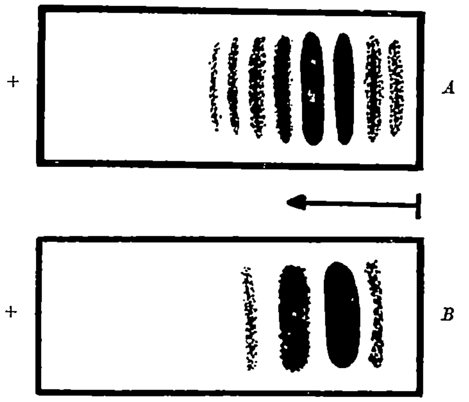

Fig. 1. Starch-gel electrophoretic patterns of zinc-α_2-glycoprotein. Native zinc-α_2-glycoprotein was analysed at *p*H 5·0 (*A*) and its sialic acid-free form at *p*H 5·6 (*B*). The ionic strength of the acetate buffers used for the gel was 0·02 and that of the electrode compartments 0·1

five bands and at *p*H 2·5 one broad zone. The best resolution was achieved on the slightly alkaline side of the isoelectric point of this globulin (Fig. 1*A*). After essential removal of its sialic acid by neuraminidase, zinc-α_2-glycoprotein was again analysed. The most distinct separation resulted between *p*H 5·5 and 6·0, and essentially two bands were observed (Fig. 1*B*). Comparable findings were obtained by investigating the barium-α_2-glycoproteins[5].

The present state of knowledge on the chemical differences between the genetic variants of certain blood proteins appears to indicate that these differences reside in the polypeptide chains of these macromolecules. Several human plasma glycoproteins with molecular weights near 45,000 reveal a resolution on starch-gel electrophoresis which is higher than that of their sialic acid-free native forms. However, transferrin, a plasma glycoprotein with a higher molecular weight and a significantly lower carbohydrate moiety, and its derivative obtained by neuraminidase digestion, show patterns the respective numbers of bands of which are in inverse ratio to those of the mentioned glycoproteins[6,7]. Thus, the present work points to the importance not only of elucidating whether the polymorphism of zinc-α_2-glycoprotein reported here is an expression of genetically determined variants, but also of initiating enquiries into the significance of the sialic acid of the plasma glycoproteins.

Biological Activity of Natural and Synthetic Insulin *A*-chain Preparations on the Isolated Rat Diaphragm

The possibility that separated insulin chains may be active to a certain extent on some of the insulin activity tests at present available has been repeatedly put to question within recent years either with insulin derivatives[1,2] or with other disulphide hormones[3]. Dixon and Wardlaw[2] demonstrated that, when all disulphide linkages of insulin were cleaved by sulphitolysis, none of the resulting thiosulphate derivatives of the *A* and *B* chains was active on glycogen deposition in the isolated mouse diaphragm or in the mouse convulsion test. If, however, the primary action of insulin on the receptor tissue is mediated by a disulphide–sulphydryl interchange, as suggested by the action of *N*-ethylmaleimide on the cell membrane[4–6], an at least partially intact disulphide structure would be required for this action.

An insulin *A*-chain derivative with an intact intra-chain disulphide bridge, *A* chain-6-11-disulphide-7,20-*bis*-thiosulphate, has been recently isolated from beef insulin by a modified sulphitolysis procedure[7].

We have now found that this compound exhibited insulin-like activity in the following three tests which have previously been proved to be mutually independent[8]: (*a*) glucose uptake by the isolated rat diaphragm (1–2 per cent activity as compared with native insulin); (*b*) incorporation of labelled inorganic phosphate (^{32}P) into 'energy rich' compounds of isolated rat diaphragm[9]; (*c*) incorporation of ^{14}C-labelled methionine in a protein fraction of the diaphragm according to Manchester[10]. However, the biological activity of *A*-chain preparations isolated from natural insulin might originate from traces of intact insulin or contaminating *B* chain which could have escaped detection by chemical means.

We have, therefore, examined a synthetic *A*-chain preparation. It was obtained from *N*-carbobenzoxy-6,7,11,20-tetra-*S*-benzyl-heneicosipeptide[11] by random air oxidation for 18 h in 0·05 per cent concentration in *tris* buffer at *p*H 8·3 after removal of the protecting groups by sodium in liquid ammonia. It may be assumed that during random air oxidation a partial recombination of the 6–11 intra-chain disulphide ring of the native *A* chain would occur. The synthetic *A*-chain preparation exhibited insulin like activity in all three tests: this activity amounted to 0·513 per cent (based on native insulin) according to the glucose uptake of the isolated rat diaphragm ($\lambda =$ 0·12, limits of error for $P = 0{\cdot}95$: 0·22 per cent and 1·49 per cent). The stimulating effect of synthetic *A* chain on the two other metabolic tests is summarized in Tables 1 and 2. Control experiments with performic acid oxidized *A* chain isolated from beef insulin showed no stimulation of uptake of glucose, even at very high levels of the *A* chain-6,7,11,20-tetra-sulphonic acid.

Thus it appears that isolated diaphragm of the rat responds to *A* chain-6-11-disulphide-7,20-*bis*-thiosulphate and to randomly oxidized synthetic *A* chain qualitatively in the same way as it does with intact insulin. The results suggest that the 6–11 intra-chain disulphide bond of insulin *A* chain may play a specific part in the mechanism of insulin action and provides a new argument in favour of a primary disulphide–sulphydryl interchange between

this hormone and its receptor in the muscle. In addition, we want to point out that recombination studies with insulin *A* and *B* chains should be considered with some caution in cases where the activities obtained are not larger than those which may be elicited by *A* chain alone. In our work (Table 3) recombinations of natural and synthetic *A* and *B* chains yielded higher activities.

Mutagenic Action of Hyponitrous Acid and Glucose Oxime

One of us has demonstrated[1-5] with his co-workers that hydroxylamine, nitrous acid, hydrogen peroxide, hyponitrous acid and oxime can induce viral nuclear polyhedrosis in healthy silkworms. Among these, the mutagenic action of the first-mentioned three substances has recently been proved by Freese[6], Gierer[7] and Wyss[8]. We have now found that acidified hyponitrite and glucosoxime produce a mutation in a bacteriophage.

Sodium hyponitrite ($Na_2N_2O_2 \cdot 8H_2O$) was prepared immediately before use, according to the method of Jones[9]. As hyponitrite is unstable, a resin was applied to remove a greater part of sodium ions: 'Amberlite *IR*-120' (Rohm and Haas Co.) was treated with hydrochloric acid, washed with water and dried under 80° C. About 200 mg of sodium hyponitrite were dissolved in 1 ml. of water, passed through a column of 2-g resin and washed with 0·5 ml. of water. The *p*H of the solution obtained was 3·5. The loss of hyponitrous acid by this treatment was negligible.

The phage used was *T*4 (Benzer), the host *E. coli B* and the medium bouillon. In order to estimate the inactivation of *T*4 and the production of its mutants, 1·3 ml. of the hyponitrous acid solution was mixed with 0·1 ml. of *T*4-phage suspension in 0·1 M phosphate buffer of *p*H 7·0 and kept at 35° C. The *p*H of the mixture was 5·2 at the beginning of incubation and 5·7 after 3 h. The concentration of hyponitrous acid in the mixture was 0·4 M and the decomposition of the acid during the incubation was less than 10 per cent. The mutants produced were *T*4*r* (*r*) and mottled *T*4*r* (*m*). Some of the results are given in Table 1.

Table 1. Inactivation and Mutation of *T*4 by Hyponitrous Acid

Reaction time (min)	Inactivation rate (*T*4/ml.)	Mutation rate ((*r* + *m*) × 100/*T*4)
0	$2 \cdot 6 \times 10^8$	0·035
60	$1 \cdot 2 \times 10^8$	0·135
180	$7 \cdot 6 \times 10^6$	0·301

In the control, it was observed that the rate of spontaneous mutation for *r* plus *m* is 0·034 per cent on the average. The experiments further showed that the production of mutants increases to a certain degree with the elevation of hyponitrous acid concentration, and that both the inactivation and mutation do not occur at the neutral reaction.

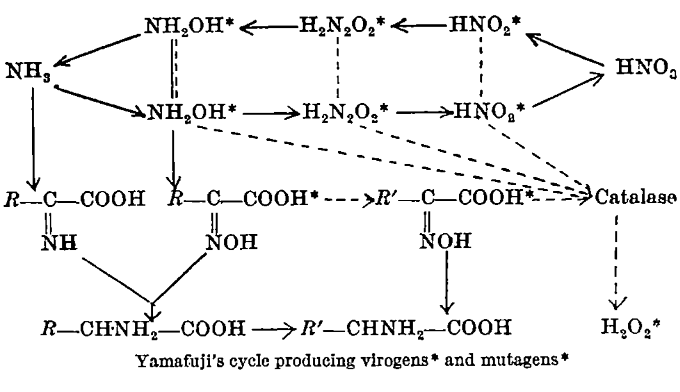
To investigate the mutagenic activity of glucosoxime, 1·8 ml. of 1·1 M oxime solution in 0·1 M phosphate buffer of *p*H 5 was mixed with 0·2 ml. of *T*4-phage suspension in 0·1 M phosphate buffer of *p*H 7 and maintained at 35° C. The *p*H of the mixture was 5·6 and there was almost no change in the acidity during the incubation. Some of the data obtained are given in Table 2.

Table 2. Inactivation and Mutation of *T*4 by Glucose Oxime

Reaction time (min)	Inactivation rate (*T*4/ml.)	Mutation rate ((*r* + *m*) × 100/*T*4)
0	$4 \cdot 7 \times 10^7$	0·040
40	$2 \cdot 8 \times 10^7$	0·077
200	$5 \cdot 0 \times 10^6$	0·533

The reaction mixture contained 0·05 M hydroxylamine at *p*H 5·6, owing to the partial hydrolysis of glucose oxime. It was confirmed, however, that the hydroxylamine of this concentration causes no mutation. The mutagenic function of hydroxylamine itself, as reported by Freese[6], can be detected in a solution of much higher concentration, in the presence of a fairly large amount of sodium chloride. We observed further that both the phage inactivation and mutant production do not take place in the mixture at *p*H 6·6.

On the basis of our discovery[10-12] of six new enzymes, we have established a nitrogen cycle[13]. On the other hand, we found that the intermediates in this cyclic reaction, hydroxylamine, hyponitrite, nitrite and oxime, inhibit cellular catalase without lowering respiration, thus leading to an accumulation of hydrogen peroxide[14-17], and that the enzymes participating in the cycle are widely distributed in animals, plants and microbes[18]. Based on these findings and the foregoing observations, Yamafuji now proposes the following scheme:



Yamafuji's cycle producing virogens* and mutagens*

It is noteworthy that normal nutritional or metabolic reactions produce a series of virogenic and mutagenic substances.

Biosynthesis of L-Serine Ethanolamine Phosphodiester

From recent work[1] it would seem that L-serine ethanolamine phosphodiester (L-SEP) is found only in the tissues of fish, amphibians, reptiles and birds. D-SEP, on the other hand, appears to be confined to earthworms[2], where it is the biological precursor of lombricine[3]. The status of the work on both isomers has been summarized by Ennor and Rosenberg[4]. These authors had previously shown[1] that dinitrophenol (3×10^{-4} M) completely inhibited the biosynthesis of L-SEP and that cytidine triphosphate (CTP) appeared to be required. Thus it was shown that chicken kidney homogenates, supplemented by CTP, incorporated more inorganic phosphorus-32 into L-SEP than when this nucleotide was omitted.

This communication is concerned with an extension of this observation and with the development of a theory to account for the biosynthesis of L-SEP.

Crude chicken kidney homogenates have been used throughout and were prepared by homogenizing 10 g of fresh kidney in 20 ml. of ice-cold 0·25 M sucrose containing EDTA (10^{-3} M) in a Potter–Elvehjem type homogenizer for 30 sec. The homogenate was centrifuged at 500*g* for 10 min at 0° and the supernatant was used without further treatment. Incubation mixtures containing 1·0 ml. of the supernatant were incubated for 1 h in phosphate buffer *p*H 7·2 at 37° in the presence of various compounds labelled with carbon-14 and in a total volume of 2·0 ml. (Table 1). At the end of the incubation period trichloroacetic acid was added; a crude phospholipid fraction was prepared from the precipitated material and L-SEP was isolated from the supernatant by previously described chromatographic techniques[6]. The radioactivities of the phospholipid fraction and of L-SEP were determined in a Packard 'Tricarb' scintillation counter.

Table 1. Incorporation of ^{14}C-Ethanolamine into L-SEP and Phospholipid in Chicken Kidney Homogenates

Additions	% of added c.p.m. recovered in	
	L-SEP	phospholipid
(1) CDP-^{14}C-ethanolamine (*a*)	8·1	22
(*b*)	8·2	7·4
(*c*)	9·5	30
(2) As (1*a*), enzyme boiled	0·4	2·0
(3) As (1*a*) + unlabelled ethanolamine phosphate	7·7	38
(4) ^{14}C-ethanolamine phosphate	0	0
(5) ^{14}C-ethanolamine	0·1	0·5
	0·4	2·0

The labelled compound added in each experiment had a radioactivity of approx. 5,000 c.p.m.

The results (Table 1) indicate that appreciable incorporation of ^{14}C-ethanolamine into both phospholipid and L-SEP was achieved only when CDP-^{14}C-ethanolamine was the isotopic source and that this incorporation was enzyme dependent. It should also be noted that neither ^{14}C-ethanolamine nor ^{14}C-ethanolamine phosphate was incorporated into the phospholipids or L-SEP and that no isotopic dilution occurred when unlabelled ethanolamine phosphate was added together with CDP-^{14}C-ethanolamine.

These results suggest that the final step in the biosynthesis of L-SEP involves the reaction:

$$\text{cytidine diphosphate-ethanolamine} + \text{L-serine} \rightarrow \text{cytidine monophosphate} + \text{L-SEP}$$

which is presumably catalysed by a specific enzyme. Work now in progress is designed to determine the existence of this reaction and the results, together with full details of the present work, will be submitted for publication elsewhere.

We thank Dr. K. P. Strickland, of the Department of Biochemistry, University of Western Ontario, for a gift of CDP-^{14}C-ethanolamine.

PHYSIOLOGY

A Biologically Active Metabolite of Vitamin A and Vitamin A Acid

A recent report by Zachman and Olson[1] described the formation of acidic water-soluble metabolites from vitamin A (retinol) and vitamin A acid (retinoic acid) by perfused rat liver. We have isolated an acidic metabolite, with potent vitamin A-like activity, from both retinol and retinoic acid. No compound metabolically related to retinol or retinoic acid with growth-promoting activity has hitherto been described.

Circumstantial evidence has for long suggested[2] that retinol is changed into an 'active form' in the course of its metabolic function. When the vitamin A-like activity of retinoic acid was discovered by Dowling and Wald[3], this acid was at first considered to be the 'active form'. However, it could not be detected in the rat, even after administration of it to deficient animals which were being cured[4]. Apparently it was extremely rapidly metabolized. Therefore, the thought arose that retinoic acid, too, is changed into the actual metabolically active compound. The metabolite reported here may be closer than retinoic acid to the active compound, or may be the active compound itself. Whether it arises naturally from retinol via retinoic acid, or independently from either, has not been determined.

Retinol-deficient rats were given retinol (1 mg in 0·2 ml. cottonseed (Wesson) oil per day) orally by intubation or retinoic acid (1 mg in 0·2 ml. aqueous saline, *p*H 8, per

† Specific activity 6·45 μc./mg (compound given orally in Wesson oil).

‡ Compound administered orally, 1·24 μc./rat/day, the last feeding 4 h before termination.

day) by intraperitoneal injection for 2 weeks and then received an intraperitoneal injection of ^{14}C-retinol or ^{14}C-retinoic acid, respectively, in amounts indicated in Table 1. The animals were killed after the time indicated, and the large and small intestine were removed and homogenized in 0·25 M sucrose containing 0·025 M potassium chloride and acetone. The supernatant solution obtained after centrifugation was concentrated and then saponified with ethanolic potassium hydroxide for 1 h at room temperature under nitrogen. After acidification, an acidic fraction could be extracted with ether. The ether extract was concentrated and the resulting mixture separated by thin-layer chromatography on Merck 'Silica gel *G*', in benzene (10): $CHCl_3$ (2·5) : CH_3OH (2·5). The mixture separated into 9 spots as shown by the faint yellow fluorescence in ultra-violet light, but 10 spots were revealed by iodine vapour. Spot No. 5, 'compound 5' (R_F 0·32), and spot No. 9, 'compound 9' (R_F 0·85), as detected by iodine vapour and counting the origin as spot No. 1, were the only radioactive spots. They were eluted separately, re-chromatographed and eluted. An ester of compound 5 could be obtained from the intestinal extract prior to saponification. On thin-layer chromatography it remained at the origin. On saponification it yielded compound 5.

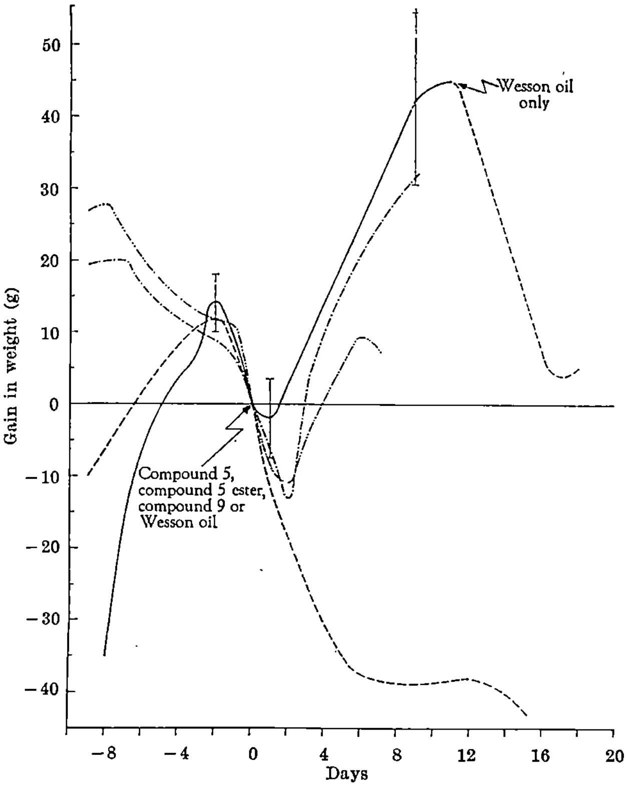

Fig. 1. Gains in weight of rats fed retinol-deficient diets and given compounds indicated, 8 μg dissolved in 0·2 ml. cottonseed (Wesson) oil per day orally by intubation, or Wesson oil alone. Vertical lines show standard deviations of weight gains for 4 rats 2 days prior, 1 day after and 9 days after administration of compound 5. Rats on compound 9 died of the deficiency on the seventh day. —, Compound 5 (4 rats). Average weight on day of administration, 141·5 g; —· —·, compound 5 ester (2 rats). Average weight on day of administration, 173·5 g; —··—··, compound 9 (2 rats). Average weight on day of administration, 135·0 g; — — —, Wesson oil (1 rat). Average weight on day of administration, 148·0 g

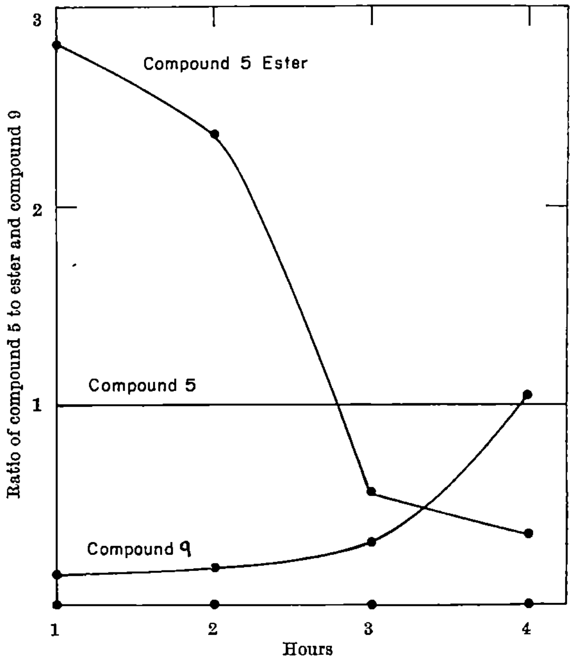

Fig. 2. Ratios of radioactivity of compound 5 ester and compound 9 to compound 5, in relation to time after injection of 6,7-^{14}C-retinoic acid, with compound 5 taken as unity

Growth curves of rats on retinol-deficient diets when given compound 5, its ester, compound 9 or Wesson oil as control are shown in Fig. 1. The curves demonstrate that weights returned to normal after feeding compound 5 or its ester for 3 days, but not compound 9; and dropped to the deficient level after withdrawal of compound 5. The rats cured from the deficiency by compound 5 not only regained their weights, but also lost their eye-lesions and ruffled fur. That compound 5 was not contaminated by retinoic acid was shown by the fact that it was radioactive after administration of labelled retinoic acid, whereas, in the same experiment, retinoic acid, when added as carrier in the isolation procedure, and obtained along with compound 5 by thin-layer chromatography, was not radioactive. Besides, the R_F of compound 5 (0·32) differs greatly from that of retinoic acid (0·82) in the solvent system used above.

The yields of compound 5 from labelled retinoic acid and retinol are shown in Table 1. It can be seen that it appears rapidly, and begins to decline after 2 h. Concomitantly, compound 9 concentration increased. The same relation holds between compound 5 ester and compound 5 (Fig. 2). It would, therefore, be tempting to suggest a sequence such as this: retinol → retinaldehyde → retinoic acid → compound 5 ester → compound 5 → compound 9.

The last column of Table 1 shows that compound 5 can also be formed from retinol. The identity and purity of compound 5 obtained from retinoic acid and retinol was further demonstrated by reversed-phase paper chromatography in 2 different solvent systems (MeOH : BuOH : H_2O, 70 : 25 : 5, and $CHCl_3$: 1 per cent acetic acid in MeOH, 2 : 1; silicone impregnated paper). Only a single spot was found for compound 5 from either precursor, different from the spots given by retinol or retinoic acid. Compound 5 occurs also in liver and kidney.

Rats cured from retinol deficiency by compound 5 are totally nightblind as determined by electroretinogram. Therefore, a conversion of compound 5 back to retinol is excluded. A conversion of compound 5 back to retinoic acid was shown to be unlikely because, when radioactive compound 5 was given to 2 rats for 3 weeks, no label was detectable in added carrier retinoic acid.

Compound 5 is obviously a carboxylic acid derived from retinol and retinoic acid, by loss of at least the carbon atom No. 15, since 15-^{14}C-retinoic acid does not yield radioactive compounds 5 or 9. Compound 5 occurs naturally as an ester with an unknown alcohol, as well as in the free form. It does not produce any colour with the Carr–Price reagent. Its ultra-violet spectrum shows a peak at 252 mμ. The infra-red spectrum shows a broad absorption band between 3,550 and 3,450 cm^{-1} (OH-group), CH_3 and CH_2 peaks (at 2,937 and 2,898 cm^{-1}), a $C{=}O$ peak (at 1,589 cm^{-1}) and a COO^- peak, possibly conjugated (at 1,715 cm^{-1}). Compound 5, therefore, has presumably 2 double bonds in conjugation with the carboxyl group, and a hydroxyl group. Attempts are now being made to determine the structure of compound 5.

We thank Prof. O. Wiss, of Hoffman-LaRoche and Co., Basle, for a gift of labelled retinol and retinoic acid, and Dr. J. E. Dowling, of Harvard University, for performing the electroretinograms. This work was supported by U.S. Public Health Service grant *HE* 07157 (*NTN*).

Hæmagglutination of Erythrocytes coated with 6-Aminopenicillanic Acid

SINCE unaltered benzylpenicillin has not been shown to be capable of forming stable covalent bonds with proteins[1], it has been suggested that the hapten complex associated with penicillin hypersensitivity involves the intermediate degradation compound D-benzylpenicillenic acid[2-4]. Levine and Ovary[4] have shown that D-benzylpenicillenic acid will react with serum proteins, especially lysine ε-amino groups, to form the mixture of diastereomers of ε-*N*-(D-α-benzylpenicilloyl)-lysine groups. Such compounds are stable antigens giving wheal and erythema reactions in sensitized individuals. De Weck and Eisen[2], on the other hand, have produced evidence that D-benzylpenicillenic acid enters into mixed disulphide linkages especially with proteins enriched with SH groups and that antibody to such complexes has an affinity for the oxazolone ring structure of D-benzylpenicillenic acid.

Previous investigations have shown that sera from certain patients treated with benzylpenicillin will agglutinate erythrocytes coated with this substance[5,6]. However, the majority of such individuals show no evidence of clinical hypersensitivity and no information is available concerning the possible identity of antigenic determinant groups involved in hæmagglutinin production and in hypersensitivity, although De Weck and Eisen[2] have suggested that the erythrocytes may in fact be coated with D-benzylpenicillenic acid, which forms rapidly in aqueous solutions of benzylpenicillin. If so, the hæmagglutinin would most likely be spatially orientated to fit the determinant oxazolone ring. The reaction of 6-aminopenicillanic acid with carbon dioxide suggested a means of determining whether this view is correct.

If human group O, Rh-negative erythrocytes are added to 6-aminopenicillanic acid, which has been dissolved in 0·85 per cent saline and the *p*H adjusted to 7·0 with sodium hydroxide to increase solubility, no hæmagglutination occurs in the presence of sera capable of agglutinating benzylpenicillin-coated erythrocytes. However, hæmagglutination occurs if 6-aminopenicillanic acid is dissolved in sodium bicarbonate solution[7]. Johnson and Hardcastle[8] have shown that in these circumstances 6-aminopenicillanic acid rearranges to form 8-hydroxypenillic acid according to Fig. 1, which involves the formation of two intermediate compounds. Compound 3 is of great interest since its attachment to erythrocytes could leave exposed a reactive determinant group, either the oxazolone ring or the thiazolidine ring depending on the mode of attachment.

Hæmagglutination tests were performed with positive sera obtained from patients treated with benzylpenicillin as previously described[6], with the modification that tubes were incubated for 0·75 h instead of 1·5 h. Successful agglutination was found to be dependent on the concentration of bicarbonate and also on the time of reaction of 6-aminopenicillanic acid with bicarbonate before addition of erythrocytes (Table 1).

Table 1

A	Conc. of $NaHCO_3$ (g %)	16	8	4	2
	Hæmagglutination	++++	++	–	–
B	Time of reaction 6-APA with $NaHCO_3$ (h)	1	4	8	24
	Hæmagglutination	++++	++++	±	–

Maximum hæmagglutination was obtained with saturated bicarbonate solutions prepared at 37·0° C (approximately 16 g per cent), and also when erythrocytes were added immediately or within 4 h to the mixture. Specifically, no agglutination occurred with bicarbonate concentrations of 4 per cent or less or when erythrocytes were added after 24 h. It appears that 8-hydroxypenillic acid is unable to coat cells and leave an active determinant group exposed to antibody in the same way that penillic and penicilloic acids also give negative results. Of the two intermediate compounds, compound 3 seems most likely to constitute the active hapten. In this event, it seems that 8-hydroxypenillic acid may in fact inhibit optimum coating of the cells since optical density measurements at 322 mμ (which is specific for the oxazolone ring structure of penicillin degradation compounds), after 24 h interaction of 6-aminopenicillanic acid and bicarbonate solution, showed that compound 3 was still present and that the reaction had not proceeded to completion under the conditions of the experiment. However, it is not clear whether this represents inhibition of attachment to the cells or a steric hindrance effect on the cell surface.

Inhibition investigations with various haptens showed that equimolar concentrations of 6-aminopenicillanic acid dissolved in either sodium hydroxide or bicarbonate

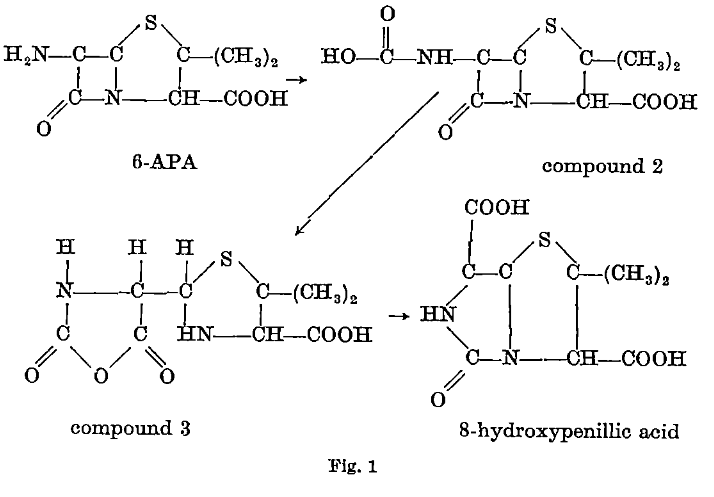

Fig. 1

gave identical degrees of inhibition (effective concentrations of 0·00075 M with a 1/8 dilution of a positive serum which agglutinated benzylpenicillin-coated cells to a titre of 1/256). Since the oxazolone ring structure would not be produced in the presence of sodium hydroxide the results suggest that the antibody is more likely to present a complementary pattern to the thiazolidine ring. This would explain the ability of penicilloic acid to inhibit the reaction and also the observation of De Weck and Eisen[2] that penillic acid and 6-aminopenicillanic acid have only very slight activity in inhibiting precipitation of D-benzylpenicillenic acid-protein conjugates in the presence of D-benzylpenicillenic acid antisera. Furthermore, hæmagglutination was inhibited by cephalosporin *C* at a molar concentration about 250 times greater than with 6-aminopenicillanic acid, suggesting a cross-reaction with the related dihydrothiazine ring.

Since hæmagglutinin is often present in sera in the absence of evidence of hypersensitivity, antibody formation associated with each of these phenomena may not depend on identical determinant groups forming *in vivo* during the degradation of benzylpenicillin.

HÆMATOLOGY

A Relationship between the *H* Chain Groups of 7*S* γ-Globulin and the Gm System

EVIDENCE has been obtained recently that 7*S* γ-globulin and myeloma proteins can be divided into three types on the basis of antigenic characteristics as well as other differences in the *H* chains[1-3]. A variety of antisera in rabbits to individual myeloma proteins as well as monkey antisera to *H* chains have served to bring out these variations. Splitting of γ-globulin with papain has also brought out differences in these three types[2]. Since the determinants involved in the Gm system have been localized to the *H* chains[4,5], it was thought of interest to test γ-globulins of the three types for the various factors involved in the Gm system. For this purpose, myeloma proteins of the three types were utilized[6,7]. Also included were investigations of the newly described Gm(*f*) factor[8], which has been found in the majority of myeloma proteins which were previously found to be negative for the Gm(*a*) and Gm(*b*) factors[9]. Striking differences in the distribution of the Gm factors were encountered for the proteins of each type.

Myeloma proteins were isolated by zone electrophoresis and were typed for Gm(*a*) (*b*) and (*f*) characters as described previously[6,7,9]. For the Gm(*a*) determinations several normal serum agglutinators were used. The Gm(*b*) reagents included both several normal serum agglutinators and agglutinators from patients with rheumatoid arthritis. Some of the Gm (*b*+) myeloma globulins were typed with three different Gm(*b*) systems with concordant results; one had been typed with five different anti-Gm(*b*), including Harboe's original anti-Gm(*b*) J. K.[10]. Two different anti-Gm(*f*) sera were used, both from donors without rheumatoid arthritis[8].

Table 1 shows the reactions of three absorbed antisera with different representative myeloma proteins. These have been selected and the numbers in different groups do not indicate the exact relative incidence. It is apparent that these antisera recognize at least four different classes of 7*S* γ-globulin. The first three groups are recognized both in a positive and a negative fashion and appear to be clear-cut classes, and are termed Vi, We and Ge groups, respectively. The fourth type at the bottom of Table 1 was only recognized as deficient by all the antisera. Other antisera in addition to those shown showed similar breakdown of the different types. Particularly striking was a monkey antiserum to *H* chains of the Vi group which gave the exact same distribution of reactivity as that obtained with the Vi rabbit antiserum. Fig. 1 illustrates the reaction of anti-Vi antiserum, unabsorbed and absorbed with Sp, with members of the Vi group of myeloma proteins as compared to those from the second groups of Table 1 (the We group).

Determination of the Gm phenotype of the myeloma proteins of the different groups brought out marked differences. All the Gm(*b*+) myeloma proteins fell into the Vi group. Four of these are illustrated in Table 1. An additional eleven Gm(*b*+) myeloma proteins were also tested and they all fell into the Vi group antigenically. The '*H* chains' from a patient Zu with H chain disease[11,12] also were Gm(*b*+) and fell into the Vi group. Two myeloma proteins which fell into the Vi group were (*a*–*b*–*f*–) including myeloma Vi itself. The incidence in a total of 84 7*S* type, myeloma proteins which were not selected on a basis of Gm type was ten Vi group myeloma proteins with eight Gm(*b*+) and two Gm(*b*–).

The majority of myeloma proteins (approximately 60–70 per cent) were found in the We group. All the Gm(*a*+) or Gm(*f*+) myeloma proteins fell into this group. No single myeloma protein contained both factors but contained one or the other factor.

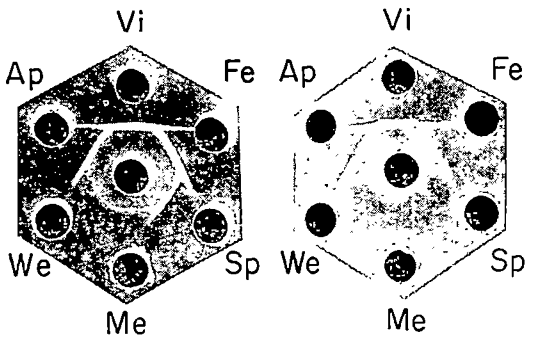

Fig. 1. Reaction of anti-Vi antiserum, unabsorbed and absorbed with Sp, with myeloma proteins of the Vi group (Vi, Ap, Fe) and heterologous myeloma proteins of the We group (We, Me, Sp)

Five myeloma proteins of the Ge group, three of which are shown in Table 1, were negative for all the Gm characters. These myeloma proteins were found to show a unique fast mobility for the F component produced by papain splitting not found with other myeloma proteins[2]. This suggests a considerable degree of individuality for this class of protein although they still cross-reacted in the F fragments with myeloma proteins of the other groups.

In addition to the Ge group, the Gm(*b*–) members of the Vi group, and the rare member of the We group, a number of other myeloma proteins were encountered which were also (*a*–*b*–*f*–). Two of these are shown at the bottom of Table 1. Most antisera showed these myelomas to be deficient but as yet no antiserum has been obtained which recognizes them in a positive fashion. Evidence also was obtained indicating that this was not a homogeneous group but consisted of a mixture of types.

Experiments on the distribution of the various groups among the molecules of normal γ-globulin indicate that they in general parallel the incidence among myeloma proteins. Quantitative precipitin analysis on twenty normal sera indicates a range for the Vi type protein from 0·1 to 1·1 mg/c.c. (ref. 2). A counterpart for the Ge group was also found and this occurred at a lower level. All sera examined, including those from whites of different Gm phenotype, negroes, Chinese and American Indians contained the Vi, We and Ge type proteins.

It has been thought in the past that genes Gm^a and Gm^b are alleles in Caucasians[10]. Certain unusual features, however, have been encountered in other racial groups[13,14]. The results presented here showed that types Gm(*a*+) and Gm(*b*+) did not occur in the same group of 7*S* γ-globulins. All Gm(*a*+) and Gm(*f*+) myeloma proteins fell into the We group which, furthermore, did not include any Gm(*b*+) proteins. It is known that the distribution of Gm(*b*) and of Gm(*f*) is very similar in Caucasians, because white individuals are, with rare exceptions, positive for both or for neither[8,9]. Combining these results, it seems possible that Gm^f (certainly not Gm^b) may be the true allele of Gm^a. It is then a reasonable concept that the 'We locus' (with Gm^a and possibly Gm^f as major alleles) and the 'Vi locus' (with Gm^b and at least one unknown allele) are closely linked. Reasoning along these lines leads to the prediction that Gm(*b*–) γ-globulins of the Vi group contain the product of the true allele(s) of Gm^b and that genes at a third locus, the 'Ge locus', as well as other loci, determine characteristics of the *H* chains of other 7*S* γ-globulin molecules.

We thank Dr. R. Bachmann, Dr. C.-B. Laurell and Dr. U. Nilsson, of the Department of Clinical Chemistry, Malmö General Hospital, for certain of the myeloma sera and myeloma fractions.

PHARMACOLOGY

Transfer of Oxytocin from the Maternal to the Fœtal Circulation in the Ewe

LITTLE is known of the transfer of peptides between the maternal and fœtal circulation. In their exhaustive review, Hagermann and Villee[1] mention the results of the work of Krzysztoporski[2], who showed that simple peptides cross the placental barrier, and those of Knobil and Josimovitch[3] that insulin crosses the mono-layered placenta of the rat. Other information on the placental penetration of peptide hormones is sparse and contradictory. High concentrations of oxytocin in maternal blood during parturition have been reported[4] and it seemed therefore of interest to investigate the possibility that oxytocin in the maternal circulation might reach the fœtus.

Table 1. OXYTOCIC ACTIVITY IN FŒTAL LAMB PLASMA BEFORE AND AFTER INJECTION OF OXYTOCIN INTO THE MATERNAL UTERINE ARTERY

Ewe No.	Days before full term	Dose of oxytocin (units)	Interval between oxytocin injection and starting collection of blood sample (seconds)	Oxytocic activity of plasma extracts mU/ml. blood	
				Control	After oxytocin injection
1	25	40	10	3·0	3·0
2	17	40	90	2·3	3·4
3	17	40	90	3·3	6·0
4	16	20	90	1·2	2·7

The experiments were carried out in pregnant ewes of the Welsh breed, in which the dates of conception were known. The ovine placenta is cotyledonary and has five layers, the fœtal and maternal circulations coming into juxtaposition in the cotyledons. About 20 days before term, the lamb or lambs were removed from the uterus by Caesarian section under spinal nerve block anæsthesia with the umbilical cord intact. (The operations were kindly carried out by Prof. Messervy and his staff.) Control samples of about 20 ml. of blood were withdrawn from the umbilical artery into heparinized syringes. Oxytocin (20–40 units 'Syntocinon', Sandoz) was injected into the uterine artery of the ewe, and a second sample of arterial blood withdrawn from the cord either before or after the oxytocin-induced contraction of the uterus. After centrifugation at 0° C the plasma was separated and extracted by treatment with acetone and ether according to the method of Ginsburg and Smith[5]. Oxytocic activity in the extracts was assayed on the superfused rat uterus[6] using 'Syntocinon' as standard. The results are shown in Table 1. Oxytocic activities equivalent to 1·2–3·3 mU oxytocin/ml. were found in control plasmas. In one experiment the second sample of umbilical arterial blood was collected 10 sec after the injection of oxytocin and before the uterus contracted; there was no difference in the oxytocic activity of the plasma before and after injection. In the remaining three experiments, in which the second samples were collected 90 sec after oxytocin injection when the uterine contraction was apparently maximal, the oxytocic activity of the second plasmas was 50–125 per cent greater than that of the controls. Treatment of the extract of the second sample of plasma in experiment 3 with thioglycollate[7] reduced the oxytocic activity from 6 mU/ml. to 3 mU/ml. blood, that is, to the level found in the control sample. It seems likely that the oxytocic activity in the control sample was due to the presence of kinins in the extract[8] but that the additional activity after injection was due to oxytocin, suggesting that the placental barrier is not impermeable to oxytocin.

A Non-cholinergic Synaptic Inhibition in the Central Nervous System of a Mollusc

Tauc and Gerschenfeld[1,2] have shown that in *Aplysia depilans* and *Helix pomatia* acetylcholine (ACh) possibly mediates synaptic excitation on neurones conventionally named *D* cells and also synaptic inhibition in other neurones called *H* cells. *D* neurones are recognized because they have only one type of input which is excitatory in character and cholinergic in nature. The analysis of synaptic activity in intracellular recording in the isolated nervous ganglia of the Argentine land-snail, *Cryptomphallus aspersa*, reveals also the presence of typical *H* and *D* cells. Besides them the perio-œsophagic ring of this snail contains also other types of neurone that in addition to a cholinergic excitatory input as in *D* cells, show a direct inhibitory synaptic input. These cells will be conventionally named here *DInhi* (*D* cells with *Inhi*bition) neurones.

DInhi neurones constitute a group of cells having a typical pattern of synaptic activity and pharmacological response. They are located in the caudal pole of the visceral ganglion, and their number is difficult to ascertain although it is certainly more than 5 or 6. In these cells, the inhibitory input may be mainly evoked by electrical stimulation of the visceral nerve, but sometimes an afference entering through the right pallial nerve could evoke a response. The inhibitory synaptic action is conveyed through an interneurone. The visceral nerve not only brings inhibitory afferences but also some excitatory ones. A single shock stimulation of this nerve provokes after a short latency period a direct inhibitory synaptic potential followed by depolarization and an excitatory burst (Fig. 1*A*). A single shock, or more often a short repetitive electrical stimulation at low frequency, provokes a repetitive firing of the inhibitory interneurone following the excitatory burst (Fig. 1*A*). This repetitive response consists of a long discharge composed by a variable number (generally 20–30) of elementary post-synaptic potentials lasting up to 40–60 sec (Figs. 1*A* and 2*A*). In Fig. 1*A* the repetitive elementary IPSP's completely inhibit the spike firing, but in other cases the IPSP only partially inhibit the spikes, and both spikes and IPSP appear intermingled in different proportions.

Inhibitory post-synaptic potentials appearing in *DInhi* cells have at the resting potential level (40–45 mV) mean amplitudes of 5–6 mV and a duration of 200–300 msec. The time course of this synaptic action is similar to that described by Tauc in *Aplysia* and *Helix*[3]. Impaling a *DInhi* cell with a double-barrelled microelectrode filled with 0·6 M sodium sulphate it was possible to pre-set the membrane potential to the desired levels. In Fig. 2, when the membrane potential is driven to − 70 mV (Fig. 2*E*), the repetitive elementary IPSP's are reversed. At a potential of about − 60 mV the inhibitory synapses do not show any overt action, and this level may correspond to the equilibrium potential of the ionic permeability change provoked by the transmitter (Fig. 2*C*). This inversion potential is similar to the reversal level of cholinergic IPSP's in *Aplysia* and *Helix*[4].

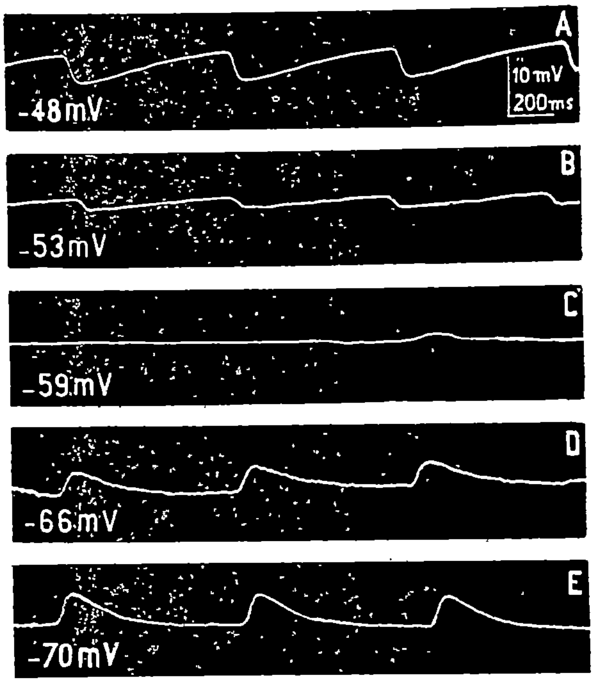

Fig. 2. *DInhi* cell impaled with a double-barrelled microelectrode. *A*, 'Spontaneous' appearing IPSP's resulting from the repetitive firing of an inhibitory interneurone. The membrane potential is driven to different levels injecting inward current through one of the barrels in *B*, *C*, *D* and *E*. Notice the reversal of IPSP's in *D* and *E*, and the inversion potential level in *C*. Potential levels are indicated in the left bottom angle of the recordings

Acetylcholine depolarizes and excites the *DInhi* neurones. Fig. 1*B* shows this effect when the drug is applied during the repetitive discharge of the inhibitory interneurone. From this evidence it becomes clear that acetylcholine cannot be the transmitter responsible for IPSP's. On the contrary, it is possible to demonstrate that D-tubocurarine and atropine sulphate block the excitatory post-synaptic potentials elicited in a *DInhi* cell by electrical stimulation of the left pallial nerve. This excitatory input generally shows up uncomplicated with an inhibitory action, as in the case of the visceral nerve stimulation.

Recent electron-microscopic[5], biochemical[6,7] and microphysiological[4] results have suggested that the gastropodal nervous system may have a complex pattern of possible synaptic transmitters. Of the other chemical substances supposed capable of acting as transmitters and normally existing in molluscan ganglia only dopamine has a constant strong inhibitory action on *DInhi* cells. These are sensitive to the drug down to a concentration of 10^{-9} M. α-Adrenergic blocking agents, such as dibenamine and dihidroergotamine, do not alter the inhibitory input to *DInhi* cells. It is not possible to demonstrate a specific activity of β-adrenergic blocking agents at the synaptic level; that is, dichloroisoproterenol blocks nerve conduction[8] and guanethidine impairs interneurone firing.

Other synaptic blocking agents, active on other vertebrate and invertebrate inhibitory synapses[9], such as picrotoxin, strych-

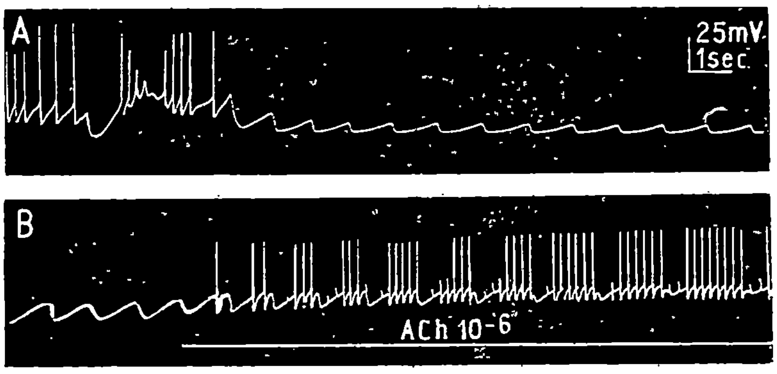

Fig. 1. Recordings from a *DInhi* cell impaled with an intracellular microelectrode. *A*, a single electrical stimulation of the visceral nerve evokes an IPSP immediately followed by an excitatory burst and the repetitive firing of the inhibitory interneurone. The latter results in a series of IPSP's giving an oscillatory appearance to the recording. *B*, during the discharge of IPSP's the application of acetylcholine 10^{-4} by perfusion depolarizes and excites the neurone

nine, tetanus toxin and metrazol, were not effective in modifying the inhibitory input to *DInhi* cells. Further work is being carried out to clarify the possible physiological role of *DInhi* neurones and the nature of the inhibitory transmitter involved in this non-cholinergic synaptic inhibition.

I thank Dr. L. Tauc for his advice. This work was supported by grants of the Consejo Nacional de Investigaciones Científicas, Argentina, and of the U.S. Air Force Office of Scientific Research (grant 654–64).

PATHOLOGY

Failure to induce Atherosclerosis in 'Triton' Hyperlipæmic Guinea Pigs

It has been shown that 'Triton-*WR* 1339', a non-ionic surface-active agent, induces high hyperlipæmia in rabbits[1], rats[2], mice[3], guinea pigs[1,4] and dogs[5]. Typical atheromasic changes of the aorta, coronary and pulmonary arteries have been demonstrated in 'Triton'-treated dogs[5]. These findings are of some interest, since dogs are usually less susceptible to atherosclerosis, and the atheromasic changes have been obtained in animals fed with a normal diet.

On the basis of the foregoing results, 37 guinea pigs of both sexes have been treated with 'Triton-*WR* 1339'. All the animals were divided into three groups and fed with a commercial standard diet to which carrots and green salad were added. Ten (first group) were not treated, 18 (second group) were given subcutaneously a 20 per cent 'Triton-*WR* 1339' in saline at a dose of 400 mg/kg every fourth day, for 19 weeks; 19 (third group) were given 'Triton' as the latter ones, and furthermore received subcutaneously a single dose of 1,000 viscosimetric units of lyophilized testicular hyaluronidase diluted into 3 ml. of saline, 30 days before the end of the treatment with 'Triton'. Treatment with hyaluronidase was given to enhance a possible atherogenic effect of 'Triton', as shown in cholesterol-fed rabbits[6-9]. All the animals were killed by cardiac puncture. The serum level of total cholesterol, phospholipids, total lipids and β-lipoproteins were determined. The entire aortæ, previously fixed in 10 per cent neutral formalin, and stained with Sudan III, were grossly and independently observed by three persons. Furthermore, the aortæ and the other organs were properly processed for histological examination.

Table 1. Average Values and Standard Deviations of Weight and Blood Lipids for the Animals of All the Groups

	No. of animals	Weight (g)		Total cholesterol (mg/100 ml.)	Phospholipids (mg/100 ml.)	Total lipids (mg/100 ml.)	Lipoproteins (%)
		At the beginning of treatment	At the end				
First group. Control untreated guinea pigs	10	435 76	432 114	48·9 13·4	51·4 28·5	192·5 40·6	93·9 3·9
Second group. Guinea pigs treated with 'Triton-*WR*' 1339	18	537 52	522 103	604·0 200·5	1,396·1 489·9	7,634·4 3,560·1	99·2 0·82
Third group. Guinea pigs treated with 'Triton-*WR* 1339' and hyaluronidase	19	517 64	500 113	572·1 187·3	1,176·2 315·2	6,761·0 2,380·5	98·8 0·54

Average values and their standard deviations of blood lipids for the three groups of animals are given in Table 1.

Serum total cholesterol, phospholipids, total lipids and β-lipoproteins are much higher in the second and third group than in the first group.

The organs and aortæ of the animals of all groups were found almost completely devoid of any change.

Chromotrope subintimal ground substance was very scarce in the arterial wall of the control guinea pigs, their endothelial cells lying just directly on the internal elastic membrane.

High blood lipids have previously been demonstrated in 'Tritonized' guinea pigs[4], but at lower levels, presumably because of the shorter period of treatment; moreover, no morphological studies on 'Triton'-treated guinea pigs have been carried out. In our experiments hyperlipæmia has not been followed by any significant change of the aortic wall or even by any lipidic infiltration of the liver, spleen and kidneys. These findings agree with the chemical results obtained by Patnode *et al.* on guinea pigs[4], although they are different from those observed in 'Triton'-treated dogs[5].

It has been shown[10] that lipolithic activity of intimal arterial layer of animals less susceptible to experimental atherosclerosis (for example, guinea pigs) is higher than that observed in the same tissues of more susceptible species (for example, rabbits). This could justify the unexpected lack of any atheromasic findings into the aortæ of the guinea pigs of the present experiments, since their endothelial cells may be particularly efficient in lipidic metabolism.

Moreover, our observations of scarce chromotrope ground substance in the intimal tissues of control untreated guinea pigs could also explain the failure to induce atherosclerosis in these animals, since the ground substance could favour the deposition of lipids into the arterial wall.

Comparative anatomical examination of the vascular structures of species differently susceptible to atherosclerosis might be worth while in this respect.

Impact of the Laser on Dental Caries

The characteristics of the laser beam which are of great interest and importance from the biomedical aspect are the ability to direct and to focus, intense energy density and some selectivity[1]. Since the laser beam is a light beam, it can be focused most accurately by using lens systems. Energy density is intense. In these experiments, the energy density was approximately 9,000 joules/cm² in the target area. Selectivity indicates that materials which are coloured absorb more of the incident beam of the lasers now available than uncoloured materials. In addition to these properties, of interest to the dentist is the fact that the duration of the impact is in the order of a millisecond.

Following a series of experiments of a study on impact of high-energy lasers, 300-joules exit energy, on bone, preliminary studies were done of the impact of the laser on teeth. These experiments were done with a pulsed ruby laser, 90-joules exit energy, beam width approximately 3/8 in., with an energy density of the focused beam of approximately 9,000 joules/cm². Some experiments were done also with special glass rods which transmitted the laser beam directly into the cavities. The teeth used in these experiments were fastened to holders on the optical bench. Pre- and post-impact pictures were obtained with a standard colour photography set-up. The teeth after impact were observed under a stereobinocular microscope. In these studies, sections have been made of the teeth by John Gray and will be reported later.

The report will be concerned with the effects on areas of caries. Subsequent reports will give details of effects of drilling of the tooth, temperature of the root canal after impacts, effect on calculi, vaporization of amalgams and porcelains and also the development of techniques to permit direct impact on selected areas of teeth in patients. In addition, impacts have been done to attempt to make the surface of the teeth more resistant to infection.

The teeth were not hot on the outside, even after repeated impacts. The effect on the area of caries varied from small 2-mm deep holes to complete disappearance of the caries tissue (Fig. 1), with some whitening of the rim around. With the use of lasers with high repetition rate of firing, the areas of destruction by focused beam will be greater. In several experiments, the unfocused beam of the laser was transmitted through special glass rods. Approximately 38 per cent of the energy was transmitted. These experiments were performed to show how the laser beam may be used in inaccessible areas on the tooth (Fig. 2). The unfocused beam with energy-levels as indicated produced broad but superficial areas of removal of the brownish carious material. Focused impacts produced deeper areas of removal of the infected material. In this series, no cultures were made pre- and post-impact, since the teeth specimens were not fresh. Thermistor readings were taken with large thermistors. Significant temperature rises were recorded. However, the response time of the thermistors was quite long and the experiments will be continued with faster thermistors.

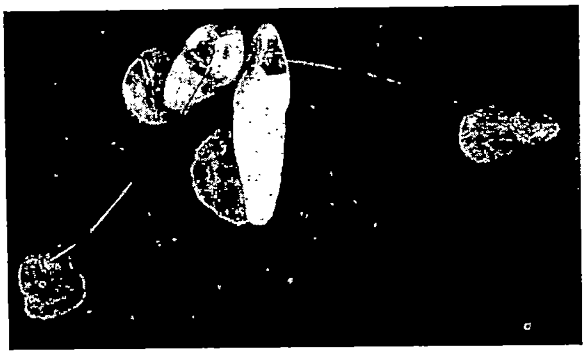

Fig. 1. Depth of impact on the buccal cusp of the lower bicuspid as compared with the impact on the mesial carious portion of the upper right central incisor. Impact from focused beam of pulsed ruby laser with exit energy of 90 joules. The increased penetration of the carious portion is due to the darker colour of this area

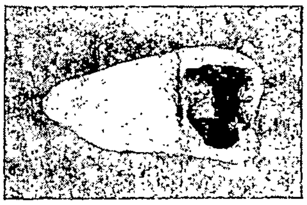

Fig. 2. Broad area of impact in a deep carious area by transmission of the laser beam through a special glass rod. The laser beam is from a pulsed ruby laser of 90-joules exit energy

Preliminary experiments indicate extensive destruction of carious areas of teeth by the unfocused and focused beams of the high-energy pulsed ruby laser. Areas of destruction were smaller but deeper with focused beams. These investigations indicate that the applications of the laser to dentistry should be examined in great detail, not only as regards basic studies, but also for the application for investigative clinical research.

IMMUNOLOGY

Production of *SV*-40 Complement-fixing Antigen

Mayer *et al.*[1] describe the preparation of complement-fixing antigen of vacuolating agent *SV*-40 in monkey kidney cell cultures. Strain No. 776 of *SV*-40 used for the work described here was obtained from Dr. H. M. Meyer. In our attempts to prepare a satisfactory complement-fixing antigen, two types of cell cultures were used: primary African green monkey kidney (AGMK) and serially propagated *BS–C*–1 (ref. 1). These cultures were obtained from Microbiological Associates, Inc., and maintained at 34° C on Eagle's basal medium containing 2 per cent agamma calf serum, 100 mg of streptomycin per ml., 100 units of penicillin per ml. and 2 mM of glutamine per ml.

Following inoculation they were fed once a week until appearance of definite cytopathic effect. With small doses cytopathic effect appeared within 3–4 weeks. With larger inocula incubation time was shortened to 2–4 days. Tissue cultures were collected at the time of maximum cytopathic effect by freezing at − 70° C. On thawing out, the cells were shaken off the glass and homogenized for 1 min at maximum speed in a Servall high-speed omnimixer. The resulting crude suspension was used as complement-fixing antigen. As antibody source, a 1/40 dilution of pooled 'normal' monkey serum with an original complement-fixing titre of 1/128 was used. At multiplicities greater than 10, relatively little complement-fixing antigen as measured in the 'microtitre' system[2] was obtained. The complement-fixing antigen yield increased significantly, however, at lower virus inputs (Table 1).

This observation was confirmed when 32-oz. flasks of AGMK and *BS–C*–1 cultures were inoculated with approximately 10–1,000 $TCID_{50}$ of *SV*-40 virus (Table 2).

Subsequent preparations of *SV*-40 complement-fixing antigen utilizing minimal amounts of seed virus and *BS–C*–1 tissue cultures have regularly yielded titres of 1 : 16 or greater and in almost every case complement-fixing and infectivity titres were higher than in cultures inoculated with the more concentrated seed (Table 3).

n, number of replicates incorporated in mean titre.
32 oz., 32-ounce flask, approximately 120 cm².
RT, roller tube cultures.
*CF 50; titres of test cultures harvested at 4+ cytopathic effect.

Preliminary experimental data suggest that the cause of this phenomenon is not interferon, nor the presence of toxin or a contaminating virus. Neither does age of the *BS–C*–1 or AGMK host cell cultures seem to influence virus yield sufficiently to explain the observed differences. Detailed investigations to elucidate this phenomenon are now being carried out.

I thank Dr. W. P. Rowe for his advice and Jean S. Y. Lee, Edith DeLong, and Jean Maryak for their assistance.

Proliferation of Transferred Spleen Cells after Antigenic Challenge

THE transfer of immunologically competent cells to an immunologically inert recipient is a technique which has been useful in the examination of the antibody-forming capacity of the donor cells. Under these conditions, circulating antibody may be found in the recipient, if the antigenic stimulation is given to the donor prior to transfer, or to the recipient after transfer[1,2]. That the donor cells are responsible for the antibody found in the recipient is evident in that disruption of the donor cells eliminates the antibody response.

In the intact animal it has been demonstrated that proliferation of antibody-producing cells occurs after the injection of antigen[3]. Lymphoid cells have been shown to proliferate after antigenic challenge in a transfer experiment, although there has been no direct evidence that the cells responsible for the antibody response undergo division. This experiment tested whether transferred antibody-forming cells divided after the injection of antigen. The combined fluorescent antibody–autoradiographic method as described by Baney *et al.*[4] was used. With this technique, antibody-forming cells are identified by the fluorescein conjugate method of Coons and the mitotic activity of the fluorescent cell is determined by an autoradiograph. The results indicate that mitosis of donor antibody-producing cells occurs after antigen injection in the recipient as well as in the intact animal.

Isologous donor B_6AF_1 mice (Roscoe B. Jackson Memorial Laboratories, Bar Harbor, Maine) were 8–10 weeks old at the beginning of the experiment. They were primarily immunized with the intraperitoneal injection of 46 μg bovine γ-globulin (BGG) nitrogen in 0·1 ml. 'Bentonite'–BGG suspension on each of three successive days 3–5 weeks prior to experiment.

A donor spleen cell suspension of 35–45 × 10⁶ nucleated cells was injected intravenously into the tail vein of X-irradiated B_6AF_1 (620 r. given one day prior to injection of cells) recipient mice of the same age.

Immediately after the injection of the primarily immunized donor spleen cells, recall antigenic challenge was provided by the injection of the recipients with 0·1 ml. of a 2 per cent solution of BGG intraperitoneally. Some recipient mice were given in addition 75 μg bacterial lipopolysaccharide (Difco) (one-half LD_{50} for these mice) in 0·15 ml. saline intraperitoneally as a non-specific adjuvant at the time of cell transfer. Each recipient received 3·3 μc. tritium-labelled thymidine (New England Nuclear, Boston, Mass.) (6·7 c./mM) in 0·1 ml. intraperitoneally three times daily. Isotope injections began immediately after cell transfer and continued until the time of killing on days 3 and 4.

After killing, brush smears of recipient spleens were made. Following fixation, the antibody-forming cells were identified by fluorescent staining. Localization of the cells was accurately recorded with the microscope vernier co-ordinates and a photograph. After autoradiography, the previously fluorescent antibody-forming cells were re-identified and an estimation of the previous mitotic activity of the cell made by counting the grains over the nucleus. Cell nuclei labelled with eight grains or more, greater than background, were considered positive.

Two experimental groups were studied. In the first, X-irradiated recipient mice received spleen cells from immunized donors plus antigenic stimulation with 325 μg N BGG. The second group was identical to the first except that 75 μg endotoxin was given to the recipient along with antigen and killed on day 3 and day 4. In both groups tritium-labelled thymidine injections began immediately after antigen injection and continued three times daily until killing. The number of antibody-producing cells which contained tritium label in the two groups is outlined in Table 1. In the first group 43 per cent of the antibody-producing cells also were tritium-labelled. In the second group, with death on day 3 and day 4, 60 and 53 per cent respectively of the antibody-producing cells were labelled with tritium-labelled thymidine. The differences in the percentages of cells labelled at the varying time periods is not significant.

Table 1. ANTIBODY-PRODUCING CELLS TRITIUM-LABELLED AFTER ANTIGEN INJECTION

	Cells + Antigen†			Cells + Antigen† + Endotoxin‡		
Day*	No. cells	No. cells labelled	Percentage	No. cells	No. cells labelled	Percentage
3				20	12	60
4	42	18	43	68	36	53

* After cell transfer and antigen injection. † 325 μg N BGG.
‡ 75 μg (one-half LD_{50}) endotoxin.

The number of non-fluorescent cells found to be randomly labelled was 4·4 per cent based on 1,000 cells counted. Control recipient animals receiving antigen alone or antigen plus endotoxin (without cells) had no clearly identifiable antibody-producing cells by this technique. No attempt was made to identify cells as to their morphological type. Hæmagglutination titration of a pool of donor sera revealed a titre of 1 : 500. Individual titrations of recipient serum at the time of killing failed to reveal significant hæmagglutinating antibody titres.

Tritium-labelled thymidine is known to be incorporated selectively into the DNA of dividing cells[5]. The presence of label in cells producing antibody is direct evidence of DNA synthesis and donor cell division in the recipient X-irradiated mouse.

RADIOBIOLOGY

Effect of Sulphydryl Reagents on the Frequency of X-ray-induced Autosomal Recessive Lethal Mutations in *Drosophila melanogaster*

IODOACETIC acid (or its derivative iodoacetamide) is known to enhance the lethal effect of ionizing radiation on mammals[1-3], mammalian cells in tissue culture[4], and bacteria[5,6]; but there are no reports of enhancement of damage which may unambiguously be called genetic. *N*-ethylmaleimide, on the other hand, enhances both the lethal and mutagenic effects of radiation on bacteria[7-9], but has not been reported to affect higher organisms. Indeed, it was shown to be quite ineffective in enhancing radiation damage to red blood corpuscles in contrast to iodoacetic acid[10].

It was decided to test for enhancement of genetic damage in an organism with structural chromosomes. The induction of autosomal recessive lethals in *Drosophila melanogaster* males was investigaged by means of the brood analysis technique[11], which tests germ cells irradiated at all stages of maturation from spermatogonia to mature sperm. Irradiations with X-rays (tube voltage 250 kV, half-value layer 1·2 mm copper) were carried out under anoxia since, with bacteria, *N*-ethylmaleimide is most effective under these conditions. Flies were placed in a container through which a rapid stream of B.O.C. 'white-spot' nitrogen was passed for 20 min before and during irradiation with 800 r. Injections (approx. 0·3 ml.) (ref. 12) of 0·4 per cent saline, or 0·4 per cent saline plus 5×10^{-4} M-*N*-ethylmaleimide (NEM) or iodoacetamide (IAAm), were carried out approximately 35 min before irradiation. Immediate survival from these treatments was 100 per cent.

Mutation frequencies in flies injected with IAAm and NEM but not irradiated did not differ significantly from the expected spontaneous frequency of 0·4 per cent. The mutation frequencies in the irradiated groups are shown in Fig. 1. So few mutants were observed in broods VI and VII that they could not be included in the statistical analysis. Cochran's test, which was applied to broods I–V, showed a significantly higher mutation frequency in the group treated with NEM compared with the saline injected group ($P \leqslant 0{\cdot}01$). The overall frequencies of induced mutants (after subtracting 0·4 per cent spontaneous mutants) were 3·99 and 2·03 per cent respectively. If mutation induction were linear with dose and if NEM acts as a dose-modifying factor[13] the enhancement ratio for NEM would be 1·97, that is, the same as that observed with bacteria[7-9]. It is not possible with the present data to compare the relative effect of NEM on different broods.

	Brood	I	II	III	IV	V	VI	VII
No. tested	Saline	347	328	342	281	351	323	276
	NEM	373	354	334	262	297	304	268
	IAAm	191	205	203	141	152	151	143

Fig. 1. The effect of injected *N*-ethylmaleimide and iodoacetamide on frequency of recessive lethal mutations after 800 rads under anoxic conditions. ○, Saline; △, NEM; ●, IAAm

Mutation frequencies in the IAAm and saline injected groups did not differ significantly from one another ($P \geqslant 0{\cdot}1$).

The induced mutations, the radiation-induced frequency of which is increased by *N*-ethylmaleimide, are probably the expression of chromosomal damage of a much grosser kind than that in *Escherichia coli*[9], where the lesion may well be confined to one of a few specific base pairs[14]. Work on enhancement with *N*-ethylmaleimide and its interrelations with the effect of oxygen is being continued.

Biological Vectors and Reservoirs of Strontium-90

THE dispersion of radioactive contamination in the environment by mobile organisms has been reported by several authors. Davis[1] noted significant amounts of radioactivity in caddis flies and midges (Orthocladiinae) attracted to lights from the nearby Columbia River. As the result of aquaria investigations on the uptake of radionuclides by aquatic insects, Peredelskii and Bogatyrev[2] concluded that a bioecological purification of contaminated reservoirs would occur as the consequence of emergent insects flying to the surrounding watershed. Auerbach[3] questioned their conclusions because the quantities of radioactivity transported by insects were less than that accumulated from fall-out. However, it was noted that lack of data on emergent insects biomass made it difficult to test the general applicability of the hypothesis. The purpose of this communication is to assess the role of emergent Chironomidae as vectors of strontium-90 and freshwater clams as reservoirs of strontium-90 in the Clinch and Tennessee Rivers.

A comprehensive investigation of the fate of low-level radioactive wastes released by Oak Ridge National Laboratory to the Clinch River has been in progress since 1959 (ref. 4). In connexion with this investigation a large collection of adult chironomids was caught in an insect light trap operated on the Clinch River bank at dusk. These adult chironomids contained $3·55 \pm 1·13 \times 10^{-6}$ μc. strontium-90/g or 8·76 times as much strontium-90 activity as an equal quantity of river-bottom sediment from that location. Investigations elsewhere[5–7] have shown emergent chironomid biomass ranges from several up to about 20 g/m^2/year, the higher productivities arising from eutrophic situations. The Clinch River is not greatly enriched with organic matter, therefore a productivity in the River of 10 g/m^2/year is a reasonable estimate. With this productivity emergent chironomids would remove $3·55 \pm 1·13 \times 10^{-5}$ μc. strontium-90/m^2/year from the river bottom. The average increment of strontium-90 from fall-out in the United States[8] between 1959 and 1960 was $4·2 \times 10^{-3}$ c./mile^2 ($1·62 \times 10^{-3}$ μc./m^2). Thus, fall-out entering the River directly would add 45 times as much strontium-90 as was removed by the emerging chironomids. Movement of insects from a contaminated terrestrial environment was found to play a similar inconsequential part in the dispersal of radioactivity[9]. It is apparent that the general dispersion of strontium-90 by insects is not of great importance.

Previous investigations[10] showed that freshwater clams concentrated strontium in their shells by factors of 2,500–9,000 times that in water and therefore are useful as indicators of strontium-90 in the environment. Since there is a commercial clam fishery on the Tennessee River downstream from the confluence of the Clinch River, calculations were made to estimate the removal of strontium-90 from the River in clam shells. The annual harvest[11] of shells ranges from about $4·5 \times 10^9$ to 9×10^9 g. By using the maximum harvest and the average strontium-90 concentration in clam shells ($7·0 \times 10^{-6}$ μc./g), the calculated removal of strontium-90 was 63 mc./year. If strontium-90 releases were constant, and if growth of the population was in equilibrium with the harvest, a similar amount of strontium-90 would be incorporated into the population each year. These mollusc populations were investigated recently[12] and from this investigation we can estimate a total population of approximately $4·5 \times 10^7$ clams in this area. Assuming a weight of 250 g for each clam (actually a high value) and using the average strontium-90 concentration, the reservoir of strontium-90 in the clams in the river is 79 mc. The annual removal and reservoir of strontium-90 in clams is small when compared with laboratory releases of strontium-90, which in the past have ranged from 22 to 150 c./year[13].

An organism having a significant biogeochemical effect on the distribution of an element in Nature must concentrate an element from its environment. In the instance of strontium-90 in molluscs, even though there is a significant concentration of strontium in their shells, there is no large reservoir of strontium-90. This is due primarily to the low specific activity ratio (^{90}Sr atoms/total Sr atoms) in the river water. In the Tennessee River[10] there are approximately 10^{10} atoms of stable strontium for each atom of strontium-90. This ratio suggests that it would be exceedingly improbable for significant quantities of strontium-90 to occur in biological reservoirs. Parker[14] estimated the total biomass that might be present in the Clinch River at any one time, and by using the maximum observed strontium-90 and cæsium-137 concentrations in fish, calculated that at most 39 mc. of strontium-90 and 8 mc. of cæsium-137 would be present in the fish population.

The transport of radionuclides by organisms within a stream[15] as well as from a stream[1] has been investigated. Detection of contaminated insects is a useful tool for examining their biology, but, when mass movement of radioactive material is considered, quantities are small. Localized problems may exist[1], but a general contamination of the landscape by mobile organisms is unlikely.

Potentiation of Virus Leukæmogenesis in *C57BL* Mice by X-irradiation or Urethane

LYMPHOID tumours can be induced in high incidence in strain *C57BL* mice by fractionated whole-body X-irradiation[1]. Urethane has also been shown to act as an independent leukæmogenic agent when administered to *C57BL* mice shortly after birth[2]. In adult mice, urethane acts as a co-leukæmogenic agent, potentiating the leukæmogenic effects of radiation or other carcinogenic agents, but exhibits little or no leukæmogenic activity when used alone[3].

The aim of the work recorded here was to examine the effect of X-irradiation and of urethane on lymphoma development induced by a virus (RLV) isolated from radiation-induced leukæmia of strain *C57BL* mice[4] and serially passaged in this and other strains for more than fifteen generations. It has previously been established that a high incidence of lymphoid tumours can be induced in *C57BL* mice by neonatal inoculation of RLV[4,5].

Strain *C57BL/Ka* mice of various ages were used in all experiments. RLV was obtained from virus-induced lymphoid tumours of strain *C57BL* mice. The pooled thymus glands, spleens, and lymph nodes were homogenized in 9 volumes of chilled phosphate-buffered saline.

The homogenate was centrifuged 10 min at 10,000*g*, and the pellet discarded. After 3 cycles of centrifugation, the final supernatant was used directly for inoculation. It was administered in intraperitoneal injections of 0·1 ml. each.

The mice were irradiated in groups of 6–10 in plastic boxes, except in experiments in which the bone marrow was to be shielded; then the mice were anæsthetized with amytal and irradiated under a 3 mm-thick lead shield, in which a window has been cut out in the area over the thymus. The physical factors of irradiation were 250 kV, 1·0 mm aluminium plus 0·25 mm copper filter, 83 r./min.

In the urethane experiments, new-born mice received a single inoculation of a cell-free centrifugate of RLV, followed by ten weekly intraperitoneal injections of urethane, starting at different intervals after RLV inoculation. When urethane administration was started 2 or 10 days after virus inoculation, the dose of urethane (dissolved in distilled water) was limited to 0·5 mg/g body-weight, to minimize leukæmogenesis by urethane itself. When urethane administration was delayed until 20 or 30 days after virus inoculation, the urethane dose was 1 mg/g body-weight.

Animals were caged in groups of 6–10, fed 'Purina Laboratory Chow' and water, and routinely autopsied at death or when moribund. The tissues were examined histologically in all but indubitable lymphomas.

Exp. 1. Mice aged three weeks were given three injections of RLV, 4 days apart. At 1–7 days after the last injection, they received the first of 4 weekly whole-body X-ray exposures of 100 r. each. Control animals received either treatment alone. In another group of mice, the treatment sequence was reversed; X-irradiation was begun at about five weeks of age, and RLV inoculations started 1–7 days after the last X-ray exposure. Control mice received RLV only at the corresponding age.

Table 1. LYMPHOMA DEVELOPMENT IN RLV-INJECTED AND X-IRRADIATED ADULT FEMALE *C57BL* MICE

Treatment RLV pre-X-ray	X-ray	RLV post X-ray	Net No. of mice	Mice with lymphomas No.	Per-cent	Age at death (days) Median	Range
+	+	–	29	28	96·6	164	125–217
+	None	–	30	8	26·7	194	109–359
–	+	–	39	17	43·6	197	155–351
–	+	+	45	35	77·8	201	152–345
–	None	+	32	4	12·5	233	180–357

The results are summarized in Table 1. Combined treatment with RLV and irradiation increases lymphoma incidence well above that resulting from either treatment alone and reduces the average latent period as well. The enhancement by the combined treatments, regardless of sequence, is significantly greater than mere summation of the components ($P < 0{\cdot}001$), suggesting a synergistic interaction between RLV and X-rays. It appears that enhancement is more marked if virus administration precedes rather than follows X-irradiation. The time interval between completion of one treatment and start of the other could be varied from 1 to 7 days without affecting the outcome. Experiments are at present under way to determine the effect of increasing this interval up to 30 days. It is not essential that the X-ray exposures be fractionated; we have obtained similar, though less pronounced, results with single 400 r. exposures.

Exp. 2. The experimental conditions were slightly modified to reduce the effects of the individual treatments. Weanling (30 ± 2 days) mice received only two injections of RLV at four-day intervals. One week later, whole-body X-irradiation was begun in four-weekly doses of 75 r. each. A second group of animals was treated similarly, except that they were shielded during irradiation, so that only the thymus area was exposed. Appropriate controls were included.

Table 2. LYMPHOMA DEVELOPMENT IN RLV-INJECTED ADULT FEMALE *C57BL* MICE AS A FUNCTION OF X-IRRADIATION

Treatment	Net No. of mice	Mice with lymphomas No.	Per-cent	Age at death (days) Median	Range
RLV injections only	41	8	19·5	215	141–304
RLV followed by whole-body X-irradiation	41	40	98	162	105–258
RLV followed by X-irradiation to thymus area	41	32	78	204	114–294
Whole-body X-irradiation only	43	2	4·6	314	294–334
Thymus X-irradiation only	41	0	—	—	—

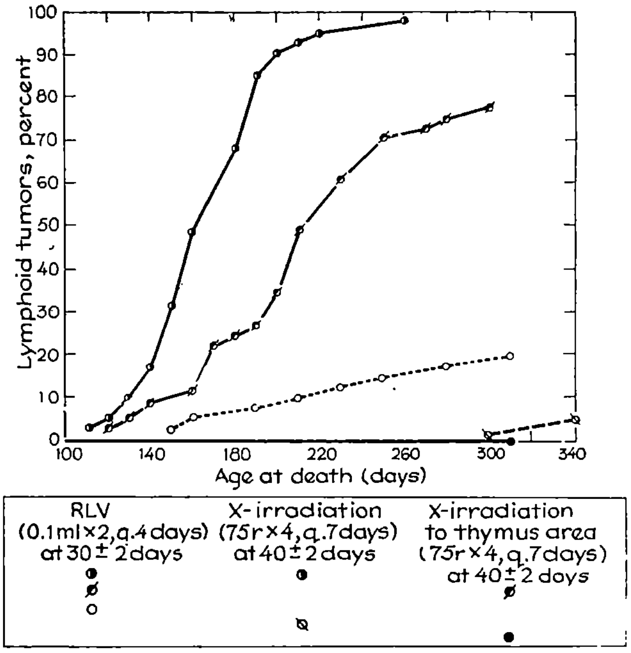

Fig. 1. Cumulative incidence of lymphomas in RLV-injected *C57BL* female mice as function of subsequent X-irradiation

The results are shown in Fig. 1 and Table 2. There is a striking enhancement of lymphoma incidence, coupled with a reduction of latent period. Synergism is even more evident here than in the previous experiment because of the low level of radiogenic lymphomas. It is interesting to note that enhancement also occurred in animals in which radiation was limited to the region of the thymus.

Exp. 3. Lymphoma incidence following combined RLV and urethane treatment was markedly increased, compared with that resulting from either treatment alone (Table 3). The response to combined treatment again exceeds expectation for simple additivity. When urethane administration was begun 2 or 10 days after neonatal virus inoculation, the average latent period for lymphoma development resulting from the combined treatment was markedly decreased, whereas when urethane treatment was delayed until 20 or 30 days after the virus inoculation, there was little decrease in latent period.

The potentiation of virus leukæmogenesis by urethane was also tested in 20-day-old mice, which received three RLV inoculations at 4-day intervals; seven days after the last inoculation, 10-weekly intraperitoneal injections

Table 3. EFFECT ON LYMPHOMA INCIDENCE IN STRAIN *C57BL* MICE OF COMBINED TREATMENT WITH RLV AND URETHANE

Treatment	Age at urethane injection (days)	Urethane dose (mg/g)	No. injections	Lymphoma incidence Nos. pos./total	Per cent	Average latent period (days)
RLV plus urethane	2	0·5	10	18/24	75	160
RLV alone	—	—	—	6/21	28	252
Urethane alone	2	0·5	10	6/29	20	312
RLV plus urethane	10	0·5	10	17/24	70	184
RLV alone	—	—	—	6/18	33	300
Urethane alone	10	0·5	10	8/36	22	330
RLV plus urethane	20	1·0	10	18/19	94	221
RLV alone	—	—	—	10/27	37	275
Urethane alone	20	1·0	10	8/38	21	320
RLV plus urethane	30	1·0	10	25/31	80	210
RLV alone	—	—	—	15/40	37	262
Urethane alone	30	1·0	10	6/31	20	322

Table 4. EFFECT ON LYMPHOMA INCIDENCE IN STRAIN *C57BL* MICE OF COMBINED TREATMENT WITH RLV AND URETHANE

Treatment	Age at RLV injection (days)	No. injections	Age at urethane injection (days)	Dose (mg/g) and No. of injections	Lymphoma incidence		Average latent period (days)
					No. pos./total	Per cent	
Group 1							
RLV plus urethane	20	3	35	1·0 × 10	24/24	100	215
RLV alone	20	3	—	—	6/9	66	212
RLV alone	1	1	—	—	10/10	100	117
Urethane alone	—	—	35	1·0 × 10	8/40	20	320
Group 2							
RLV plus urethane	20	3	35	1·0 × 10	17/30	56·6	215
RLV alone	20	3	—	—	1/16	6·2	366
RLV alone	1	1	—	—	0/15	0	> 388
Urethane alone	—	—	35	1·0 × 10	6/28	21	330

of urethane (1 mg/g body-weight) were administered. Two different serial passages of the leukæmia virus were used in this experiment. The results are presented in Table 4. In Group 1, the RLV preparation proved too active to allow full expression of the potentiating effect of urethane. Significant potentiation was observed in Group 2, using an RLV preparation from another serial passage, which had minimal activity alone in either newborn or 20-day-old mice.

In all experimental groups the tumours were typical lymphocytic lymphosarcomas, identical with those arising after irradiation of adult mice or RLV inoculation of neonatal *C57BL* mice[1,4].

It is concluded that X-irradiation and urethane potentiate the leukæmogenic activity of RLV in mice of strain *C57BL*. Enhancement of susceptibility to other oncogenic viruses by radiation has been reported[6-8]. The mechanism of this potentiation is not established. Depression of the host's immunological defences is probably not an important factor, since X-ray dosage was relatively low. A more likely explanation is perhaps provided by the fact that irradiation and urethane cause thymic injury and regeneration, with a concomitant repopulation by immature lymphocytes. The presence of these cells has been correlated with susceptibility to virus leukæmogenesis[9,10]. When bone marrow is shielded during irradiation, as in Exp. 2, thymic repair proceeds at a more rapid rate, thus shortening the period of prevalence of the immature lymphocytes. This may explain the lesser enhancement observed in these animals.

The present result with urethane is in striking contrast to the inhibition of lymphoma development by urethane in *C3Hf*/Lw* mice carrying the Moloney leukæmogenic virus[11]. Perhaps investigations of the latter strain, comparable to our work on strain *C57BL* with respect to the capacity of urethane to produce concomitant thymic and bone-marrow injury[12], would help to reconcile these apparently antithetical observations.

BIOLOGY

Effect of Photoperiod on Cyclic Patterns of Body Temperature in the Quail

THE nature of body temperature rhythms in gallinaceous birds can best be described when exogenous factors such as disturbances, movement (muscular activity), and temperature extremes are controlled. Normal fluctuations in body temperature usually are associated with concomitant forms of daily activity. The magnitude of variation differs considerably among species. In chickens kept in an uncontrolled, but moderate, environment the diurnal differential in body temperature is approximately 1·3° C (refs. 1 and 2). The highest body temperature occurs at 1700 h and the lowest at 0400 h. In a controlled environment where temperatures were held constant at 21·1° C, the diurnal body temperature change in chicken was 0·17° C (ref. 3). The body temperature of Gambel quail (*Lophortyn gambelii*) maintained at ambient temperatures between 24° and 26° C fluctuates between 40° and 41·5° C during the day and has a range approximately 1·5° C lower during the night[4]. Most investigators agree that activity *per se* is the principal factor which causes change in body temperature. Since the light period induces or exaggerates activity, it is of interest to determine the influence different photoperiods have on altering the circadian changes of body temperature in coturnix (*Coturnix coturnix japonica*).

The body temperature of six mature coturnix females kept in individual cages (5 in. × 7 in. × 10 in.) in a temperature and light-controlled chamber was measured continuously with a Minneapolis–Honeywell 16-point potentiometer. Average daily room temperature ranged from 19·5° to 25° C. The birds were subjected to artificial incandescent light.

Plastic coated copper-constantan thermocouples (24-gauge) were inserted into the abdominal cavity of each bird through an incision approximately 2·5 cm dorsal and 2·5 cm posterior to the tip of the keel. Each thermocouple lead was shaped snugly to the side of the body and secured to a harness ring on the top side of an adjustable quail harness (Le Captive adjustable quail harness, manufactured by Kennel Crafts, Inc., Orlando, Florida). The leads were laced through a piece of spiral plastic wrapping. One end of the wrapping was fastened to the upper ring of the quail harness; the opposite end was attached to the top of the cage. The coiled wrapping allowed the quail to move freely, except that it restricted rotational movement. Individual body temperatures were recorded every 8 min. The birds were given 7 days to recuperate after insertion of the thermocouple before the experiment was started.

Temperature curves for the five light treatments are shown in Fig. 1. In treatment 1, the daily body temperature fluctuated between 41·8° and 42·4° C. The average body temperatures for the light and dark periods were 42·2° and 41·9° C, respectively. Maximum temperature occurred at 1300 h and the minimum at 2400 h. The daily fluctuation in body temperature was less than that reported for chicken (1·3° C (ref. 2)) and for Gambel quail (1·5° C (ref. 4)).

Shifting the light period to the interval between 2000 and 1000 h without changing the total increment of

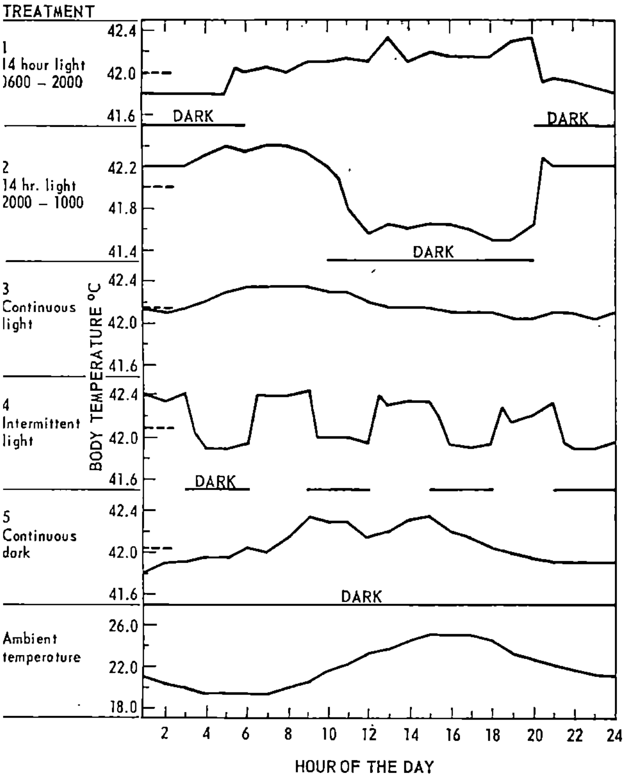

Fig. 1. Mean hourly body temperatures of *Coturnix* exposed to different photoperiods. Data for mean room temperature included. Broken lines represent mean temperatures for the 24-h period

light (treatment 2) resulted in a change of the body temperature pattern. In all birds the rhythm of the body temperature shifted in response to the new light schedule within 24 h. Average body temperatures during the light and dark periods were 42·3° and 41·6° C, respectively. The mean temperature during the dark period (1000–2000 h) was less than the mean of 41·8° C recorded in treatment 1, even though the period of darkness in treatment 2 occurred during hours of natural daylight.

The average daily fluctuation in body temperature of coturnix given continuous light was 0·3° C. The relatively small fluctuation in daily body temperature of coturnix kept in a moderately controlled environment is comparable to that reported for chickens[3]. From general observations it appeared that the birds became relatively inactive several times during the day.

The relationship between photoperiod and the period of activity is demonstrated clearly in treatment 4, where the birds were exposed to an intermittent light schedule of 3 h light and 3 h dark. The mean body temperatures for the light and dark periods were 42·4° and 42·0° C, respectively. The average minimum temperature of 41·9° C recorded during the 1st, 2nd and 4th dark periods approaches the minimum body temperature of 41·8° C recorded for the same birds in treatment 1. These data imply that, on the onset of the dark period, the temperature regulatory mechanism(s) rapidly can adjust the body temperature to a level typical of the resting stage.

The average maximum body temperature of the birds kept in continuous darkness (treatment 5) was recorded at 0900 h. The increase in body temperature started at 0600 h and began to decline at 1500 h. This period roughly coincided with the outside light period of the day. It is doubtful that the minor changes in room temperature would have initiated an activity response, since Bartholomew and Dawson[4] reported that in a sustained environmental temperature of 39° C the daytime temperature of Gambel quail was not elevated above that normally maintained in the absence of heat stress.

Table 1

Treatment	Duration of treatment (days)	No. of females	Light cycle on–off
1	5	6	0600–2000
2	7	6	2000–1000
3	7	6	Continuous light
4	7	5	Intermittent light (3 h L : 3 h D)
5	7	4	Continuous dark

During the experiment the quail displayed excitement when approached for the purpose of checking thermocouples or for servicing feeders and waterers. The degree of excitement depended on whether the birds were handled. When handled, their temperature increased approximately 1·0° C within 8 min; it returned to normal about 16 min later. This fright reaction is not uncommon in fowl. The body temperature of ruffed grouse (*Bonasa umbellus umbellus*) increased to 0·8° C when the birds were removed from the cage and forced to run for 10 min (ref. 5). The body temperature of the eastern house wren (*Troglodytes aëdon aëdon*) was reported to increase 2·2° C following capture[6]. However, the temperature dropped very soon after the birds quieted down.

From results of the tests recorded here, it appears that normal cyclic fluctuations in temperature of birds kept in moderate environments are associated with concomitant forms of physical activity which usually are restricted to the light period. In these tests, it was possible by imposing different experimental photoperiods to alter the rhythm of body temperature in coturnix.

Mechanism of Capacitation of Rabbit Spermatozoa

Rabbit spermatozoa must be exposed to the environment of the female tract for several hours before acquiring the capacity to fertilize ova[1,2]. This phenomenon was termed capacitation[1], and appears to be a general requirement for fertilization in several species[3,4]. Chang[4] later discovered that spermatozoa capacitated *in utero* could be decapacitated by brief incubation in seminal plasma. Decapacitation appeared to be due to a definite substance in seminal plasma[5].

With the discovery of the decapacitation factor in seminal plasma it appeared possible that capacitation was removal of the spermatozoa from seminal plasma and hence removal of the decapacitation factor as the spermatozoa progressed up the female tract. Two lines of evidence opposed this hypothesis. Austin[1] and Chang[2] showed that epididymal spermatozoa must be capacitated. Bedford and Chang[5] showed that the decapacitation factor existed in seminal plasma from vasectomized males. This evidence suggested that epididymal spermatozoa do not contact the decapacitation factor until the time of ejaculation yet must undergo capacitation. It occurred to us, however, that since the tubular portion of the male tract has a common embryonic origin, the decapacitation factor could exist also in the epididymis and hence contact the spermatozoa before ejaculation. Demonstration of the decapacitation factor in epididymal fluid would support the hypothesis that capacitation is the removal or inactivation of the decapacitation factor. We report in this communication the decapacitation of capacitated spermatozoa by epididymal fluid and their recapacitation on further *in utero* incubation.

Epididymal fluid was collected by distending the excised epididymis (still attached to the testis) with air injected through the stump of the vas deferens. A cut was made in the epididymis, the fluids pressed out, and the epididymis flushed with calcium-free Krebs–Ringer phosphate solution. The final volume was adjusted so that 1 ml. contained the flushings of two epididymes. Spermatozoa were removed by centrifugation at 1,100*g* for 10 min and the supernatant frozen. Uterine spermatozoa were obtained by flushing each excised uterus with 5·0 ml. of Krebs–Ringer phosphate solution 12–15 h after natural, multiple matings and observed for motility. The spermatozoa suspension was divided, centrifuged at 400*g* for 3 min and concentrated to 0·6 ml. The treated spermatozoa were incubated with 0·2 ml. of epididymal fluid for 30 min at room temperature. The control spermatozoa were subjected to an identical treatment except that Krebs–Ringer phosphate solution was substituted for epididymal fluid. Good motility was observed after both treatments. Two preparations of epididymal fluid were used in these experiments each of which produced 100 per cent decapacitation of uterine spermatozoa. 2 h after ovulation surgical insemination was performed on virgin New Zealand does, 6–8 months old, which had been in isolation for at least 21 days and had received 3·3 mg of pituitary luteinizing hormone (Armour-Baldwin Laboratories) by intravenous injection 12 h earlier. The rabbits were anæsthetized with sodium pentobarbital and ether, a midline incision was made, and 0·05 ml. of spermatozoa suspension containing $0·76–12 \times 10^4$ cells was injected into each oviduct through the infundibulum at a depth of approximately 2·0 cm. Treated spermatozoa were placed in one oviduct and the controls in the other. Following surgical closure, each doe received 100,000 units procaine penicillin *G* and 0·125 g streptomycin sulphate intramuscularly. Ova were recovered 26–40 h later by flushing from the oviducts and observed for regular division characteristic of fertilization. Table 1 illustrates the results of these experiments in which 40 out of 50 (80 per cent) of the control eggs were fertile, while none of the eggs inseminated with spermatozoa which had been incubated in epididymal fluid were fertilized. These results indicate that the spermatozoa had become capacitated and that treatment with epididymal fluid prevented fertilization.

Table 1. REVERSAL OF CAPACITATION WITH EPIDIDYMAL FLUID

Additions to capacitated spermatozoa	Ova recovered	Fertile	Non-fertile
None	50	40 (80%)	10
Epididymal fluid	38	0	38

Table 2. RECAPACITATION OF DECAPACITATED SPERM

Spermatozoa treatment	Ova recovered	Fertile	Non-fertile
Freshly ejaculated, washed	13	8	5
Decapacitated with epididymal fluid	16	15	1

To establish that the spermatozoa were not permanently damaged by incubation with epididymal fluid and to demonstrate that epididymal fluid contained a substance with decapacitation factor action, spermatozoa treated with epididymal fluid were recapacitated. The spermatozoa were capacitated as before, incubated in epididymal fluid, and injected into the uterine lumen with a 24-gauge needle 4 h prior to ovulation. Washed, ejaculated spermatozoa served as controls in this experiment.

The results in Table 2 show that capacitated spermatozoa decapacitated with epididymal fluid were recapacitated by *in utero* incubation. (In the control group one oviduct contained 5 ova in which spermatozoa had penetrated the zona pellucida, but the ova failed to cleave.) This demonstration of recapacitation shows that the decapacitation factor in epididymal fluid has the same functional properties as described for decapacitation factor in seminal plasma[5].

The data contained herein suggest the hypothesis that capacitation is the inactivation or removal of the decapacitation factor from sperm. This is not in conflict with Chang's[2] observations that epididymal sperm must be capacitated and that the decapacitation factor is also produced in the male tract below the vas deferens[5]. The hypothesis is also consistent with Austin's[1] suggestion that ejaculated spermatozoa contain an inhibited mucolytic enzyme which permits ovum penetration and capacitation is removal of the inhibitor.

Besides the foregoing experiments on the epididymal decapacitation factor, we have confirmed and slightly extended earlier work on the decapacitation factor of seminal plasma. Bedford and Chang[5] showed that decapacitation factor activity was removed from seminal plasma by ultracentrifugation and resuspending the pellet in the seminal plasma would restore activity. We have found that ultracentrifugation of seminal plasma at 105,000*g* for 4 h gave a pellet which retained activity after washing and resuspending in buffer, thus demonstrating that the supernatant of the seminal plasma was not necessary for decapacitation factor activity.

This investigation was supported in part by a U.S. Public Health Service fellowship 1–*F3*–*GM*–22,244, Grant *GM* 10034 and Career Award 5–*K3*–*GM* 483 from the National Institute of General Medical Sciences. We also thank the Population Council for Grant *M*–6424.

Mallophaga on Catarrhine Monkeys: *Colobus guereza*, a Natural Host of *Procavicola colobi**

ACCORDING to Hopkins and Clay[1] and Eichler[2] no Mallophaga exist on Old World monkeys. An adult female *Colobus* monkey (*Colobus guereza guereza* Rüppell, 1835), however, collected in Djam-djam, Shoa Province, Ethiopia, by Prof. D. Starck in 1956 and now in the collection of the Anatomical Institute of Frankfurt, was found to be heavily infested by *Procavicola colobi* (Kellogg, 1910). This species was first described as *Trichodectes colobi* from *Colobus guereza caudatus* Thomas, 1885, at Mount Kilimandjaro. Eichler[3] made *Trichodectes colobi* the type species of a new genus *Meganarionoides* based on the description by Kellogg. Werneck[4] has re-examined Kellogg's specimens and has found that they are members of *Procavicola*, a genus otherwise known from many species of hyraxes (Procaviidae) only. He recognizes *Meganarionoides* as a sub-genus of *Procavicola*. Werneck doubted that the natural host of *Procavicola colobi* was a *Colobus* monkey, especially as he has found a second lot of *Procavicola colobi* at his disposal contaminated with other mallophaga, obviously originating from Procaviidae. Consequently, he suggested that the natural host is *Dendrohyrax validus*. In this he has been followed by Hopkins[5] and Hopkins and Clay[1].

Our *Colobus* monkey from Ethiopia has never been in contact with a *Dendrohyrax* or any other Provaviidae after its death. Yet we have found hundreds of eggs and adult and larval *Procavicola* on it, all clasping the hairs tightly;

---

* Results of the Ethiopia Expedition, 1956, No. 10.

most of them on the back and on the throat. The eggs are clearly distinguishable from those of the sucking-louse, *Pedicinus pictus* Ferris, 1934, some specimens of which have also been found on this monkey. There is no doubt in our opinion that *Colobus guereza* is a natural host of *Procavicola* (*Meganarionoides*) *colobi*.

Considering the general host-specificity and the supposedly parallel phylogeny of hosts and Mallophaga, it is interesting to find a member of a group of Mallophaga, which is otherwise confined to Procaviidae, on a monkey. Eichler[3] had united the ischnoceran Mallophaga parasitizing primates in the sub-family Cebidicolinae of Trichodectidae. In 1963, after Werneck's investigation, he removed *Meganarionoides* from this sub-family. But even the relationship of the two remaining genera (*Lorisicola* from the slow lemur (*Nycticebus*), and *Cebidicola* from some New World monkeys) seems highly uncertain. Hopkins and Clay[1] consider *Lorisicola* "doubtfully distinct from *Felicola*", a genus widespread on carnivores. In any event, it seems hazardous to base any theories about the relationship of lemurs and New World monkeys on the relation of their parasites, *Lorisicola* and *Cebidicola*, as, for example, Vanzolini and Guimarães[6] have done.

The Mallophaga probably have never been able to colonize the primates in populations sufficient to enable them to follow the phylogeny of these hosts, due possibly to the intensive care given to the skin by most primates. Suitable niches have opened, for example, in the nocturnal *Aotes* (*Aotiella*, Amblycera) or the thumbless African *Colobus* monkeys, in which sucking-lice of the genus *Pedicinus* also have reached a climax in numbers of species and individuals among Old World monkeys[7]. These niches must have been occupied by different Mallophaga invading from different orders of hosts.

Nucleic Acid Content of Chloroplasts of Spinach isolated by a Non-aqueous Technique

THERE is strong evidence for cytoplasmic inheritance of chloroplasts in higher plants. This genetic autonomy, together with the demonstration of protein synthesis[1,2] and the presence of ribosomes[3-5] in chloroplasts, has generated considerable interest in the nucleic acids associated with chloroplasts.

Many investigators have reported the occurrence of chloroplast nucleic acids[6], but there is considerable quantitative disagreement in these results. This is undoubtedly in part due to differences in the material analysed and the analytical methods utilized. These methods include cytochemical procedures, which depend on the specific staining of RNA and DNA in the chloroplasts of intact cells, and the chemical analysis of RNA and DNA extracted from chloroplasts isolated in isotonic aqueous media. A more recent technique is the incorporation of tritium thymidine into *Spirogyra*[7] or tobacco leaves[8], and intracellular localization by means of autoradiography. Electron microscopy indicates the presence of DNA in *Chlamydomonas* chloroplasts[9]. Sedimentation investigations in cæsium chloride density gradients indicate that DNA extracted from higher plant chloroplasts[10], and algal chloroplasts[10,11], differs in density from that of the nucleus.

Table 1

	Mg polynucleotide per 100 mg non-aqueous chloroplasts			
Method of analysis / Treatment	Ultra-violet absorption (260 mμ)	Diphenylamine test for deoxyribose	Orcinol test for ribose	Phosphate
(1) Strong acid hydrolysate (5% perchloric acid, 15 min, 90° C)	7·95 (DNA + RNA)	0·40 (DNA)	7·80 (DNA)	8·10 (DNA + RNA)
(2) Mild alkaline hydrolysate (0·3 N KOH, 16 h, 34°C)	7·49 (RNA)	0	7·10 (RNA)	7·62 (RNA)
(3) Residue from (2) after strong acid hydrolysis, as in (1)	0·795 (DNA)	0·37 (DNA)	0	0·41 (DNA)

The amounts of nucleic acid reported in chloroplasts using cytochemical procedures are at the lower limit of the sensitivity of the method[6]. This lack of sensitivity is circumvented by direct chemical analysis of polynucleotide extracted from isolated chloroplasts. However, in this procedure, artefacts are encountered, owing to contamination of the plastids by nucleic acids from other cell components during isolation. This contamination has been elegantly avoided for chloroplasts DNA by Baltus and Brachet[12], whose results were confirmed by Gibor and Izawa[13]. These workers removed the nucleus of *Acetabularia*, prior to chloroplast isolation and analysis. Additional errors in these experiments may also arise by the loss of nucleic acids from chloroplasts either by leakage[14], or enzymatic degradation, particularly when aqueous isolation procedures are used. However, these difficulties are largely avoided if plastids are isolated by the non-aqueous method. This communication reports the chemical estimation of RNA and DNA in spinach chloroplasts isolated by a non-aqueous density technique.

Chloroplasts were isolated by modifications of methods by Heber[14]. Polynucleotides were estimated by the Smillie–Krotkov modifications[15] of the Schmidt–Thannhauser procedures. The purity of the chloroplasts was checked by phase microscopy after staining with methyl green, and an electron micrograph taken by one of us (R. B. P.) of a similar preparation has been published by Heber[16]. This micrograph, together with enzymatic checks by Heber, also demonstrates the purity of the preparations.

100-mg samples of non-aqueous chloroplasts were extracted with methanol, cold trichloroacetic acid, ethanol and ethanol–ether mixtures, and the insoluble residues were either subjected to mild alkaline hydrolysis for RNA nucleotides, or strong acid hydrolysis for total nucleotide estimations. The results are summarized in Table 1.

The confirmation of values obtained by analysis of deoxyribose and phosphate is good. However, the high value obtained from ultra-violet absorption at 2600 Å for DNA suggests interference by some hydrolysis products other than nucleotides. This emphasizes the necessity of working with several complementary analytical methods in such an investigation.

These results show that the chloroplasts prepared by the non-aqueous technique contain 0·5 per cent DNA, and 7·5 per cent RNA by weight. An objection to these data might be that a considerable portion of the plastid lipid was extracted during the isolation procedure, yielding high nucleic acid contents on a weight basis. That this is not the case is shown by other experiments[17], in which non-polar solvents were shown to extract not more than 5 per cent of the chloroplast mass.

The value obtained for the DNA content of non-aqueous chloroplasts is in good agreement with previous reports for aqueous chloroplasts. The value obtained for the RNA content is considerably higher than that reported previously (2–4 per cent), and this difference is probably due to the application of the non-aqueous technique for the isolation of chloroplasts. It is likely that RNA is leached from chloroplasts isolated from aqueous cellular homogenates, whereas this is minimized by using non-aqueous techniques. In addition, the action of the chloroplast RNase[18] is inhibited by operation in a non-polar medium.

In order to localize the polynucleotides within the chloroplasts, stroma and grana fractions were prepared[17] and analysed using the same procedures. The polynucleotides were found to be in the stroma fraction and easily leached out of the chloroplasts by means of aqueous buffers.

In summary, the DNA content of spinach chloroplasts prepared in non-aqueous media is similar to that of chloroplasts prepared in aqueous buffers. However, the RNA content of non-aqueous chloroplasts is higher than that of aqueously prepared chloroplasts by a factor of two. The RNA is localized in the stroma phase of the chloroplast and is not bound to the quantum conversion apparatus. It is suggested that the low RNA content of aqueous chloroplasts is due to leaching[6] of the polynucleotide during chloroplast isolation.

Thermophylaxis in Bean Rust

Thermophylaxis is here defined as sensitivity to heat resulting from a previous exposure to heat. The phenomenon has been demonstrated clearly only with bean (*Phaseolus vulgaris*)[1] and the uredinial stage of the bean rust fungus (*Uromyces phaseoli*) in bean, but preliminary results with cowpea and with the powdery mildew, *Sphaerotheca fuliginea*, indicate that thermophylaxis may be demonstrable in many species. This report deals only with *Uromyces*, with which the phenomenon seems better expressed than with the other plants indicated.

Pinto beans infected with rust and growing in a greenhouse at about 23° were first heated (predisposed) for 10–20 sec at 45° in a water bath at 2–4 days after inoculation. One primary leaf on each plant was predisposed and the opposite leaf of each plant served as a control. This predisposition dosage was about 1/3 the ED_{50} or 1/6 the ED_{100} for rust of this age, and in itself caused only a barely perceptible delay in rust development if the plants were allowed to remain in the greenhouse. In such plants the rust in the predisposed leaves soon became more tolerant to heat than the control rust[2]. In the work recorded here the inoculated and predisposed plants were placed in a dark incubator at an air temperature of about 38° for 1–7 h (predisposition lag), given a challenge heating of 0–50 sec at 50° in a water bath, returned to the greenhouse, and the number of living pustules counted or rated about 10 days after inoculation. Under these conditions rust in predisposed leaves was killed at a lower challenge heat dosage than rust in the control leaves (Fig. 1), and if the plants were left at 38° for more than 4 h the predisposed rust was usually killed without any additional challenge heat.

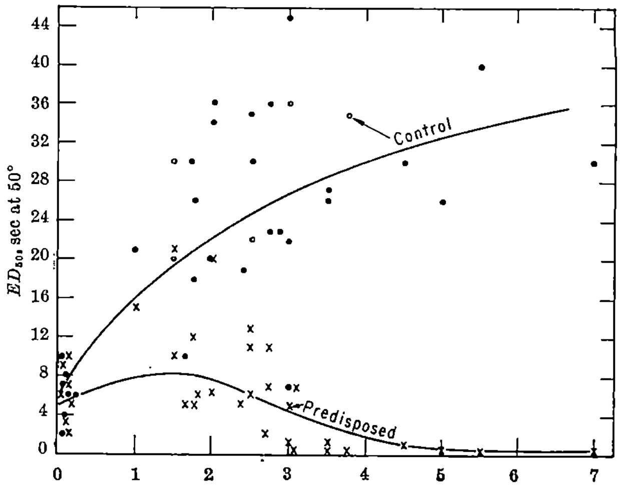

Fig. 1. Simultaneous adaptation and sensitization to heat in bean rust (*Uromyces phaseoli* on *Phaseolus vulgaris*) at 38° C

If predisposed plants were subjected to a range of challenge heats immediately after the predisposition heating of one leaf, the rust in the predisposed leaves was killed at a slightly lower challenge heat dosage than necessary to kill the rust in the control leaves, but this is regarded as an additive effect of the predisposition heat dosage plus the challenge heat dosage. Thermophylaxis can be said to occur only if the predisposed rust is killed at a dosage less than the combined predisposition heat dosage plus challenge heat dosage applied to the control leaf of the same plant. The degree of thermophylaxis can be expressed as an adaptation index[2] which is the ED_{50} of the challenge heat for the predisposed leaf divided by the ED_{50} of the challenge heat of the control. Adaptation indexes greater than 1 indicate adaptation. Adaptation indexes less than 1 indicate an additive effect of heat or thermophylaxis. Logically and experimentally (predisposition heat of 15 sec at 45°, ED_{50} for control of 5 sec at 50°, and a temperature coefficient of 120) an adaptation index less than 0·7 would not and has not resulted from the additive effect alone. Since the adaptation index after 2·5–7 h at 38° was always less than 0·7 in each of 16 trials (Fig. 1), and averaged only 0·13, it is concluded that thermophylaxis occurred.

Almost as interesting is the observation that adaptation in the control (non-predisposed) and sensitization in the predisposed rust mycelium occurred simultaneously in the same environment. That is, the ED_{50} of the control increased with increasing exposure to 38°, while the ED_{50} of the predisposed rust on the same plants decreased. The apparent rise in the ED_{50} of the predisposed rust between 0 and 2 h after the predisposition heat is likely a transient effect or an adaptation artefact because the temperature of the low heat capacity incubator (150 W) dropped temporarily to as low as 32° within a few minutes after the 6–12 pots of plants were placed in the incubator.

The degree of thermophylaxis reported here (0·03 times as much heat necessary to kill the rust in predisposed leaves as in control leaves) is much greater than the degree of heat adaptation previously reported[2], where 4 times as

Formative Response of *Amsinckia intermedia* to the Interrelated Effects of Low Temperature, Thiamin and 2,4-Dichlorophenoxyacetic Acid

THE adverse effect of temperature on plant growth may sometimes be corrected by the external application of certain essential metabolites. As early as 1943, Bonner[1], using *Cosmos sulphureus* Cav. as experimental plant material, found that the growth under sub-optimal temperature conditions was improved by thiamin application. Later work by Bonner[2] and more recently the experiments by Ketellapper[3] showed that both high- and low-temperature effects on several plant species were overcome by chemical treatments. The investigations recorded here were carried out to determine whether or not the response of fiddleneck (*Amsinckia intermedia*, Fisch and Mey) to 2,4-dichlorophenoxyacetic acid (2,4-D) when grown at a low temperature can be changed by treatment with certain metabolites.

Seedlings were grown in plastic pots containing 16-mesh silica sand in the greenhouse for one month and then placed in a growth chamber. Subsequent culture was at 10° C under an 18-h light régime. Illumination was provided by warm white fluorescent tubes supplemented with 60-W incandescent bulbs giving an intensity of 1,250 ft.-candles. Nutrients were supplied to all plants every other day with Hoagland's solution.

In the initial set of experiments, solutions of thiamin were applied with a pipette to individual mature leaves in 0·01 ml. droplets at rates of 0·05–50·0 μg per plant. At the same time, 500 μg of 2,4-D alone or in addition to each of the rates of thiamin was applied to similar plants.

In other experiments, fiddleneck seedlings were established as described here, and weekly treatments of certain metabolites were sprayed on the foliage. Thiamin (20 p.p.m.), vitamin C (1,000 p.p.m.), *d*-biotin (1 p.p.m.), pyridoxin (20 p.p.m.), nicotinic acid (40 p.p.m.), adenine (1 p.p.m.), 2-thiouracil (1 p.p.m.), and a mixture of amino-acids (L-cystine, L-cysteine, L-glutamic acid, DL-aspartic acid and glycine—each at 1 p.p.m.) were sprayed on the leaves. The plants were sprayed with the solutions weekly for four consecutive weeks and then gathered. The root and shoot of each plant were separated and the dry weight measured. The metabolites which caused an improvement in growth at this temperature (10° C) were then applied to similar plants in combination with 2,4-D to determine the interaction. Treatments were 275 μg 2,4-D per plant, plus one of the following additives: amino-acid mixture, *d*-biotin (0·1 and 10 μg), nicotinic acid (10 and 100 μg) or thiamin (10 μg). Observations were recorded one month after treatment.

The untreated and the thiamin-treated plants grew slowly at 10° C with no apparent morphological differences due to the thiamin. 2,4-D applications alone suppressed growth and produced a slight distortion of the apex, 2,4-D plus 0·05 μg thiamin caused 100 per cent mortality (Fig. 1), and 2,4-D plus 0·5 μg thiamin caused mortality to 40 per cent of the plants and severe injury and distortion to 60 per cent. The 2,4-D plus the higher rates of thiamin (2·5, 5·0 and 50 μg) caused severe injury but did not kill the plants.

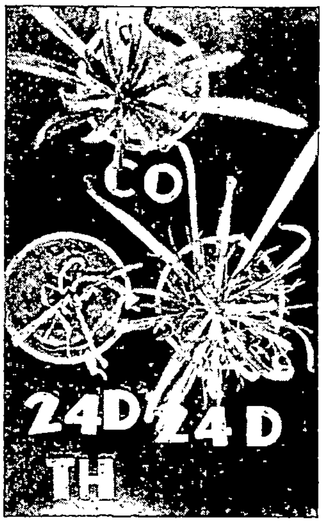

Fig. 1. *Amsinckia intermedia* plants growing at 10° C. Control plant (*CO*), plant treated with 2,4-D (2,4D) at lower right and plant treated with 2,4-D plus thiamin (24DTH) at lower left. Combination of thiamin and 2,4-D causes increased mortality at this temperature

The plants sprayed with the amino-acid mixture, *d*-biotin or nicotinic acid were darker in colour than the control plants and dry weight of both tops and roots was greater. 2,4-D applied to otherwise untreated plants caused a suppression of the apex and some distortion of the youngest leaves. *d*-Biotin (0·1 μg) plus 2,4-D caused severe swelling of the apex, suppression of new growth and discoloration and necrotic areas in the mature leaves. *d*-Biotin at a dosage of 10 μg plus 2,4-D had much less effect. Nicotinic acid at the rate of 100 μg per plant increased the response of the plant to 2,4-D but did not do so at 10 μg. Thiamin-treated plants were the most severely injured by the 2,4-D, although they showed no improvement in growth from the thiamin treatment.

The results show that: (1) low-temperature effects on *Amsinckia intermedia* may be partially overcome by the application of chemical substances; (2) certain metabolites in combination with 2,4-D are more effective in causing formative and toxic effects on *Amsinckia intermedia* growing at a sub-optimal temperature than 2,4-D alone. Of those tested, thiamin was the most effective.

A Steroid Growth Factor Requirement in a Fungus

THE homothallic oomycete *Phytophthora cactorum* is frequently grown on oatmeal agar[1], and on this medium it forms oospores readily. On a basal medium of sucrose or glucose, asparagine, mineral salts and thiamine its vegetative growth is less and oospores are not formed, or a very few are found after a long time, and then only at the edge of the colony. The basal medium evidently lacks some growth factor or factors present in oats. The addition of aqueous extracts of ground oat grains to the basal medium stimulates vegetative growth but does not lead to the production of oospores. However, the addition of 500 mg/l. of a petroleum ether or ethanol extract of oats both increases the rate and amount of growth and results in the production of oospores. Aqueous and ethanol extracts of peas have similar effects.

Aqueous extracts of peas and oats also stimulate the vegetative growth of *Phytophthora parasitica* and *P. palmivora*, but the alcohol or petroleum ether extract must also be added for sexual reproduction in these species.

In testing fractions of the extracts from ground oats (and later, pure substances) for their activity, *P. cactorum*, strain I.M.I. 21168, obtained from the Commonwealth Mycological Institute, was grown at 25° in 5-cm Petri dishes containing 4 ml. of medium. A known amount of material for testing was dissolved in diethyl ether and added to the basal medium[2] together with agar, and the medium was then autoclaved. (The activity of the crude extract was not lost on autoclaving the extract with the medium at 120° for 15 min.) The inoculum was a plug 4 mm in diameter cut from a culture growing on the basal medium. The resulting colonies were examined for the occurrence of oospores, and their number and time of appearance were noted; the diameter of the colony was also measured.

After removal of the phospholipids, the crude petroleum ether extract was chromatographed on alumina, to give three main components consisting of vegetable oils (60 per cent) and two more polar yellow oils (5 and 10 per cent respectively) eluted with benzene/chloroform (1 : 1) and ethyl acetate respectively. Activity was found to be associated with the second yellow oil; this material was saponified and yielded a neutral red waxy solid (5 per cent) and fatty acid material (75 per cent).

The red waxy solid afforded sterols on crystallization and these were found to be active. Sterols were also obtained from the vegetable oil by saponification and digitonin precipitation of the neutral material, and were likewise found to be active. Previous investigation[3] of the sterols from oat grains had demonstrated the presence of β-sitosterol together with two di-unsaturated sterols tentatively identified as $\Delta^{5,11}$- and $\Delta^{7,11}$-stigmastadienol respectively, and a trace of stigmasterol. The sterol mixture from the red waxy solid was separated into mono- and di-unsaturated compounds by chromatography of the acetates on 10 per cent silver nitrate on silicagel. Abundant oospores were produced when both these fractions were added to the basal medium at 10 mg/l., after 5 days with the former and 8 days with the latter. Examination of these two fractions by gas chromatography indicated that the former, mono-unsaturated fraction consisted largely of β-sitosterol together with small amounts of cholesterol, campesterol and Δ^{7}-stigmastenol, and the di-unsaturated fraction contained two principal components together with small amounts of brassicasterol and stigmasterol and a number of other unidentified trace components. The ultra-violet spectrum of the crude sterol mixture indicated the presence of about 1 per cent of a $\Delta^{5,7}$-diene system similar to that of ergosterol (cf. ref. 3).

Since it appears that sterols are active materials in inducing oospore formation, a number of pure steroids and related compounds were tested, at concentrations (in the final medium) of 10 mg/l., with the results shown in Table 1.

Leonian and Lilly[4] found a growth factor necessary for sexual reproduction of *Phytophthora cactorum* in an alcoholic extract of peas, but they considered the active fraction was not the sterols themselves but rather was merely absorbed on them. By the use of pure samples we have shown that sterols are in fact active growth factors.

It would appear that some step or steps in the synthesis of sterols is blocked; but the absence of exogenous sterols does not prevent vegetative growth. When 51 g (dry weight) of mycelium, produced from growth on 15 l. of liquid basal medium, was extracted with petroleum ether, and the resulting 10 per cent of fatty material saponified, no sterols could be detected in the neutral fraction on precipitation with digitonin followed by gas chromatography. The blockage in sterol synthesis thus appears to be complete. Further, we find that the vegetative growth in the basal medium is not inhibited by nystatin (up to 100 mg/l.), which is believed to act by combining with sterols in the protoplast membrane[5].

Table 1. EFFECTIVENESS OF STEROIDS AND RELATED SUBSTANCES IN OOSPORE PRODUCTION IN *Phytophthora cactorum*

Substance added to basal medium	No. of oospores	Distribution in culture	Time for production
Cholesterol	+ + + +	Throughout	5–6 days
Cholesterol acetate	+ + + +	Throughout	5–6 days
Ergosterol	+ + + +	Throughout	5 days
Stigmasterol acetate	+ + + +	Throughout	8–10 days
Cholest-5-ene-3-one	+	Only at edge	10–11 days
Cholest-4-ene-3-one	+	Throughout	10–11 days
Cholest-4,6-diene-3-one	+	Throughout	10 days
Cholestane	+	Only at edge	14 days
Coprostan-3-one	±	Only at edge	10 days
Calciferol	−	—	—
Diosgenin	−	—	—
Tomatidine	+	Only at edge	14 days
Δ^{5}-Pregnen-3β-ol-20-one	+	Only at edge	14 days
Progesterone	+	Only at edge	14 days
Testosterone	+	Only at edge	14 days
Dehydroepiandrosterone	+	Only at edge	14 days
Œstrone	+	Only at edge	14 days
Squalene	−	—	—
DL-α-Tocopherol	+	Only at edge	14 days
Sodium acetate	+	Only at edge	14 days
None (control)	+	Only at edge	14 days

±, Fewer oospores than in control; −, no oospores.

When sterols are added to the basal medium, growth is increased and sexual reproduction occurs. Of the substances we have tested (Table 1), the sterols themselves are most active. Dehydrogenation at C3 to the ketone (as in the cholestenones) results in lower activity, but it does not always seem to destroy it completely. With the cholestenones, the total number of oospores is not appreciably greater than in the controls, but the oospores appeared several days sooner and were (in two cases) found throughout the culture. Derivatives in which the side-chain is greatly modified (for example, diosgenin) or shortened (progesterone, testosterone, etc.) are apparently ineffective.

Sterols have been recorded as essential growth factors for certain protozoa[6,7], a *Labyrinthula*[8] and pleuropneumonia-like organisms[9,10], but this appears to be the first record of a sterol requirement by a fungus.

MICROBIOLOGY

Relationship between the Products of Aromatic Biosynthesis in *Mycobacterium smegmatis* and *Aerobacter aerogenes*

MYCOBACTERIA, when grown on Proskauer and Beck medium, accumulate salicylic acid[1]. This accumulation is greatly increased by iron-deficiency. The results presented here suggest that this acid originates from an intermediate in the main pathway of aromatic biosynthesis.

Mycobacterium smegmatis was grown either on Proskauer and Beck medium (which contains glycerol and asparagine) or on: quinic acid 5·0 g, L-glutamine 1·25 g, L-asparagine 1·25 g, glycerol 5·0 g, KH_2PO_4 5·0 g, $MgSO_4$ 0·4 g, and water 1 l., made to *p*H 6·8 with sodium hydroxide. In some cases a medium containing shikimic acid 0·1 per cent, $(NH_4)_2SO_4$ 0·15 per cent, with KH_2PO_4 and $MgSO_4$, as above, was used. *Aerobacter aerogenes* was grown on: quinic acid 2·0 g, glutamine 0·5 g, $(NH_4)_2SO_4$ 1·0 g, KH_2PO_4 5·0 g, water 1 l. and made to *p*H 6·8 with sodium hydroxide.

With both organisms, the medium, after growth, was freed from cells, reduced to 1/20th of its original volume, acidified to *p*H 2 and extracted with ethyl acetate. The extract, after drying, was evaporated to about 0·3 ml. and examined by paper chromatography.

Salicylic acid accumulated after growth of *M. smegmatis* on Proskauer and Beck medium. Iron-deficiency greatly increased this accumulation[1]. After growth on either quinic acid or shikimic acid, the amount of salicylic acid found was greater than before; also identified were anthranilic, 3 : 4-dihydroxybenzoic, 4-hydroxybenzoic and 4-hydroxyphenylacetic acids. When *M. smegmatis* was grown on Proskauer and Beck medium and this replaced either by a further quantity of the same medium or by shikimic acid medium, and growth continued for 24 h, more salicylic acid accumulated in the latter medium. Deficiency of iron increased the accumulation of salicylic acid in both cases.

Small amounts of anthranilic and 4-hydroxybenzoic acids were found after growth of *A. aerogenes* (wild-type *NCW*) on quinic acid medium, After iron-deficient growth a considerable amount of 2 : 3-dihydroxybenzoic acid was also produced. With a mutant of *A. aerogenes* (*N*5/36—blocked immediately after the synthesis of anthranilic acid). anthranilic acid, 3 : 4-dihydroxybenzoic acid and an *N*-acylanthranilic acid were found after growth on the quinic acid medium supplemented with 2 μg/ml. of L-tryptophan. Very little change was produced by iron-deficiency. The *N*-acylanthranilic acid derivative which was found had spectra in the ultraviolet region at several *p*H values which were very close to those given by both *N*-formyl- and *N*-acetylanthranilic acids. The material was shown not to be the formyl derivative by chromatographic mobility and by its greater stability to 3 N hydrochloric acid. Hydrolysis with 6 N hydrochloric acid at 100° gave anthranilic acid, but the rest of the molecule has not yet been identified.

Some work has also been carried out with *Escherichia coli* growing on 2 per cent glycerol (it is unable to utilize quinic acid): 2 : 3-dihydroxybenzoic, 4-hydroxybenzoic and 3 : 4-dihydroxybenzoic acids have been located on chromatograms of extracted medium.

Salicylic acid in *M. smegmatis* seems to arise from the main pathway of aromatic biosynthesis, as is shown by the stimulatory effect of shikimic acid, or quinic acid, on its output. Further, it seems to have an origin close to that of 2 : 3-dihydroxybenzoic acid in *A. aerogenes* and probably *E. coli* as well. This is suggested by the fact that iron deficiency affects only these compounds among the number of aromatic compounds produced, as well as by their closely related structures. The origin of 2 : 3-dihydroxybenzoic acid in *A. aerogenes* is after the paths of aromatic biosynthesis diverge and before the synthesis of either tyrosine or anthranilic acid[2]. Thus, this may also be the point of origin of salicylic acid. It is interesting to note that salicylic acid, like 2 : 3-dihydroxybenzoic acid, is not metabolized once it has been excreted into the medium.

It was suggested that salicylic acid might arise through non-introduction of an amino group into a precursor of anthranilic acid, and that its accumulation in iron-deficiency is due to a requirement for iron for the insertion of the amino group[1]. Some support for this idea is given by the finding by Srinivasan and Rivera[3,4] that Fe^{++} is a co-factor in the conversion of 3-enolpyruvylshikimic acid 5-phosphate to anthranilic acid by cell-free extracts of *E. coli.*

The *N*-acylanthranilic acid either is a precursor of anthranilic acid or a metabolite of it: it will be difficult to reach a conclusion on this until the acyl group has been identified. One interesting possibility arising from the first alternative is that in the conversion of chorismic acid[5] to anthranilic acid a bi-cyclic intermediate may be formed as in Fig. 1.

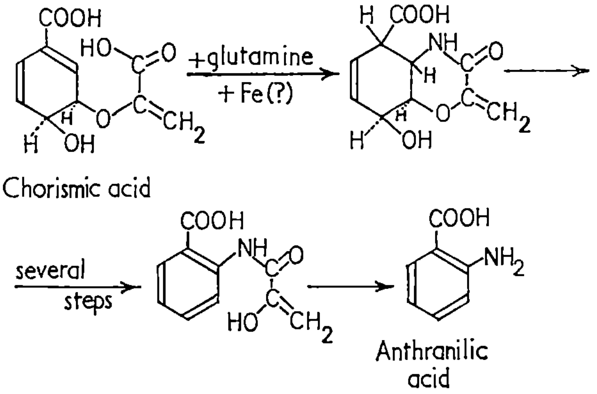

Fig. 1

It is possible that analogous steps, without the introduction of the nitrogen atom, are involved in the synthesis of an alternative bi-cyclic intermediate, which in *Mycobacteria* is hydrolysed to salicylic acid and in *A. aerogenes* yields 2 : 3-dihydroxybenzoic acid.

The wild-type and mutant *A. aerogenes* were part of a gift from Dr. F. Gibson, University of Melbourne. This work was supported by grant *AI* 02842 from the U.S. Public Health Service and by Arthur Guiness, Son and Co. (Dublin), Ltd. I thank Mr. Frank Winder for his criticism and help with this work, and Dr. V. C. Barry for his advice.

Effect of Deuterium on Starving Bacteria

The presence of high concentrations of deuterium oxide in growth media has been shown to be toxic to bacteria[1]. The effects are characterized by long lag periods before growth occurs and subsequent slow growth with the production of distorted forms. However, experiments designed to study the effect of deuterium oxide on bacteria starving in buffer solutions showed that deuterium oxide was not toxic under these conditions and that the longevity of the bacteria was increased.

Aerobacter aerogenes N.C.T.C. 418 was used as the test organism, and it was grown in continuous culture at 40° C in a synthetic medium with glycerol as limiting substrate[2]. The storage conditions were those used by Postgate and Hunter (*loc cit.*).

Although the increased longevity was easily detected in suspensions containing 15 μg dry weight of bacteria per ml.

and was found to be related to the concentration of deuterium oxide, the effect was more conveniently studied in suspensions containing about 1 mg/ml. dry weight, which represents about $2{\cdot}5 \times 10^9$ organisms/ml., in 75 per cent deuterium oxide. The results of an experiment carried out at this concentration of organisms are shown in Fig. 1. The mean half-life of the suspension stored in aqueous buffer is $12{\cdot}9 \pm 1{\cdot}0$ h and for storage in a buffer containing 75 per cent deuterium oxide, $16{\cdot}6 \pm 2{\cdot}9$ h. The limits represent 95 per cent fiducial limits and were kindly calculated by Mr. S. Peto. The survival curve in 75 per cent deuterium oxide is characterized by an extended initial phase during which the viability falls off more slowly than in the final part of the curve.

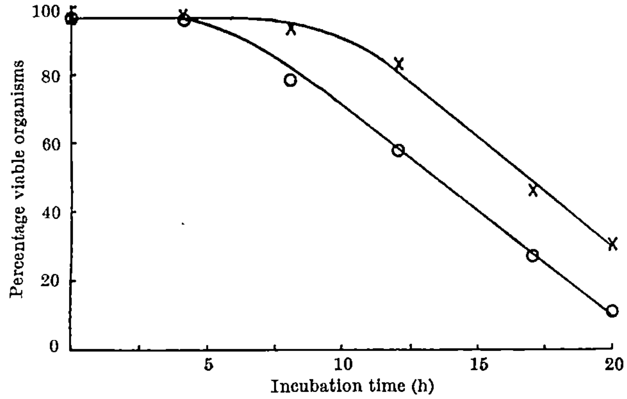

Fig. 1. Change in viability of washed suspensions of *A. aerogenes* incubated at 40° C in saline-*tris* buffer *p*H 7·1. ○, Aqueous buffer solution; ×, buffer solution containing 75 per cent deuterium oxide

Deuterium oxide will permeate the whole of the cell, and rapid exchange will occur with ordinary water present in the cell substance. An isotope effect could then occur if the processes involved in maintaining viability utilized deuterium oxide. Since energy is derived from ribonucleic acid and protein during starvation[2,3] investigations were carried out to see whether an isotope effect could be observed in the breakdown of these substances.

Little difference was found in the protein and ribonucleic acid content of samples of bacteria taken during storage in either aqueous buffer or buffer containing 75 per cent deuterium oxide. The suspending fluids and the materials released from the bacteria by treatment with cetyl trimethyl ammonium bromide were examined for substances absorbing at 260 mμ. It was found that a slightly slower release of these substances occurred from bacteria stored in buffer containing 75 per cent deuterium oxide.

Although a number of enzymes are involved in the breakdown of nucleic acids the effect of 75 per cent deuterium oxide on the endogenous ribonuclease, polynucleotide phosphorylase and phosphodiesterase was conveniently examined *in vitro* using the conditions described by Wade[4], and Wade and Lovett[5]. Deuterium oxide had very little effect on the rate of breakdown of nucleic acid by phosphodiesterase and polynucleotide phosphorylase, but the effect on the action of ribonuclease was considerable (Fig. 2). In view of this result, it was of interest to investigate the effect of deuterium oxide on a bacterium which had no ribonuclease. Wade and Robinson[6] have recently demonstrated that *Pseudomonas fluorescens* (N.C.I.B. 8248) does not contain ribonuclease, and preliminary experiments with organisms grown in continuous culture at 30° C in a medium similar to that used by Postgate and Hunter (*loc cit.*), except that citric acid was substituted for EDTA, showed that 75 per cent deuterium oxide did not increase the longevity of washed organisms suspended in a saline-*tris* buffer at 33° C. EDTA was omitted from the saline-*tris* buffer as it was highly toxic to the organisms.

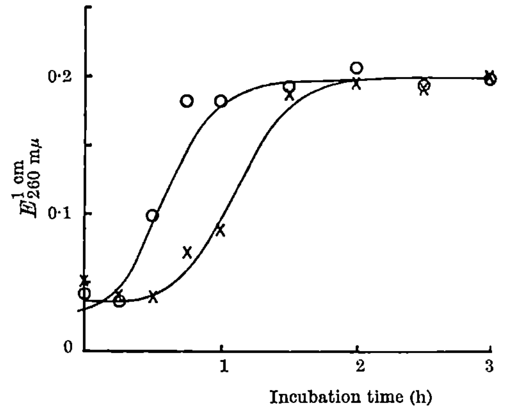

Fig. 2. Curves showing the release of acid-soluble substances adsorbing at 260 mμ from a suspension of 14 mg/ml. dry weight of *A. aerogenes* incubated at 37° C in a buffer containing 0·145 M NaCl, 10 mM magnesium chloride, 10 mM sodium phosphate and 40 mM EDTA. The final *p*H was adjusted to 7·0 with NaOH solution. The bacteria were killed before the experiment by treating with cold 50 per cent aqueous acetone and any remaining acetone removed by evaporation under vacuum at a temperature not exceeding 5° C. ○, Aqueous buffer solution; ×, buffer solution containing 75 per cent deuterium oxide

Although the effect of deuterium oxide on bacterial proteinases has not yet been investigated, the results so far obtained show that under the starvation conditions described for *A. aerogenes* deuterium oxide retards the rate of hydrolysis of ribonucleic acid which is partly used as an energy source in maintaining the viability of the organism. After a certain proportion of the ribonucleic acid is utilized another process ensues which is not retarded by deuterium oxide.

Antibiotics of *Alcaligenes faecalis*

Alcaligenes faecalis type cultures N.C.T.C. 8764 and A.T.C.C. 9220 were investigated for bacteriocin production against members of the same species[1] as well as a large number of *Escherichia*, *Salmonella*, *Serratia*, *Staphylococci*, Gram-positive aerobic bacilli and *Proteus*[1]. The methods used were those of Fredericq[2]. Organisms were grown on the Pr_3 media of Ben-Gurion and Hertman[3]. Electrophoresis was performed as previously described[4].

The two *A. faecalis* type cultures were found inhibitory for many members of the same species as well as strains of *Proteus hauseri*, *rettgeri*, and *morganii*. Large clear areas of inhibition were produced in the indicator lawns. In addition, A.T.C.C. 9220 was also inhibitory for a number of *Staphylococcus* strains. These antibiotics are bacteriostatic in that sub-cultures from the clear areas of inhibition always yield growth identical to the original strains and, despite repeated attempts, no resistant mutants have yet been obtained. The antibiotics pass through 10 mμ filters and cellulose-dialysis tubing.

Electrophoresis of these inhibitory agents was done with representatives of each of the sensitive *A. faecalis* and *Proteus* strains as indicators of activity (Fig. 1). In each case the same pattern was encountered. This consisted of a clear round area of inhibition towards the cathode. These results indicate that a single inhibitory substance is produced by each of the two strains.

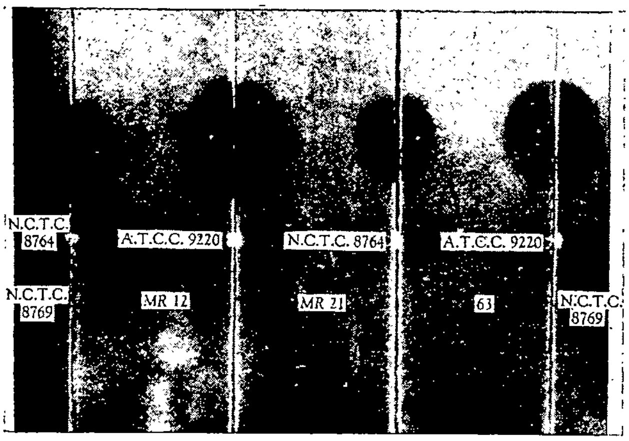

Fig. 1. Type cultures, N.C.T.C. 8764 and A.T.C.C. 9220, were each inoculated on two places in the centre of an electrophoresis plate and grown for 36 h. The growths were then killed with chloroform vapour and a potential of 50 V applied across the plate for 16 h in a refrigerator. The plate was divided into 5 compartments with glass strips through the centre of each inoculum and the plate again sterilized. The compartments were then covered with soft agar containing the indicator strains *P. mirabilis* 63, *P. rettgeri MR* 12, *P. morganii MR* 21 and *A. faecalis* strain N.C.T.C. 8769. The plate was incubated overnight

The antibiotic produced by A.T.C.C. 9220 was further investigated. Sterile cellulose disks were placed on agar plates and the organisms spread on the surfaces. After 3 days' incubation at 37° C, the disks and organisms were stripped from the surfaces and the clear agar stored at −15° C overnight. On thawing, the clear fluid was precipitated in the cold with an equal volume of alcohol–acetone (50 per cent v/v). The precipitate was collected by centrifuging at −10° C and freeze-dried. The freeze-dried material was dissolved in 0·1 M phosphate buffer *p*H 7·4. Dilutions were spotted on a freshly poured indicator lawn and incubated overnight. An inhibitory titre of 1 : 4 was obtained. No activity could be demonstrated with the above method without the use of cellulose disks to separate the organisms from the antibiotic produced in the agar. The activity of the antibiotic solution was destroyed by heating at 85° C for 0·5 h and was not affected by pepsin or trypsin. The spectrum of activity of the antibiotic in solution was identical to that produced by the organism on agar and showed the same electrophoretic mobility.

A large number of other *A. faecalis* strains examined were inhibitory for several members of the same species as well as *Escherichia*, *Salmonella*, *Shigella*, *Serratia*, *Staphylococci*, Gram-positive aerobic bacilli and *Proteus*.

Origin from Mitochondria of the Double-walled Viral Membrane in *Saccharomyces*

Investigation of the viral infections of *Saccharomyces*[1,2] has shown that this organism is parasitized by both a rod-shaped virus (like tobacco mosaic virus) and a double-walled, spherical, nucloid virus. Electron microscopy, in this laboratory, on the ætiology of yeast infection has been carried out on strains affected by the spherical, double-walled, nucleoid virus[3]. Electron micrographs show that the site of propagation of the virus is the mitochondrion and that the outer double wall of the virus is derived from the double-walled cristæ of the mitochondrion. Fig. 1 shows the mitochondria of a normal yeast cell. Fig. 2 shows a focus of viral infection multi-

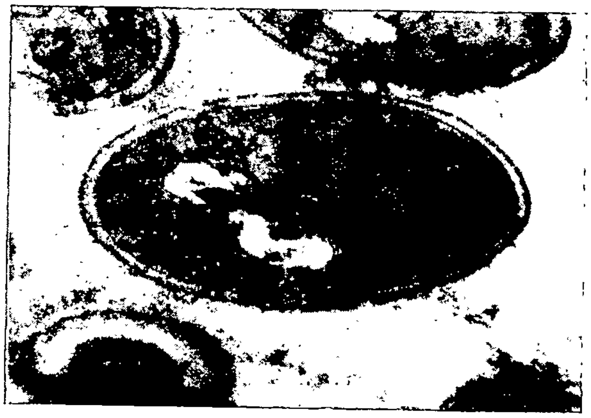

Fig. 1

GENETICS

Occurrence of Transferrin D_1 in Korea

So far, sixteen electrophoretically distinguishable transferrin variants have been distinguished by means of starch-gel electrophoresis[1,2]. Observations on the frequency and distribution of the variants have been recently summarized by Giblett[3]. In all populations examined transferrin C is by far the most frequently encountered. Those variants which occur in a measurable gene frequency are usually restricted to certain populations. Transferrin D_1 is widely distributed and has been reported most frequently in American and African Negroes. It has also been reported as occurring in New Guinea, Fiji, New Hebrides, Malaya, Thailand, Philippines, Formosa, Ceylon, India, Central and South America and Sweden.

Recently, however, using a modification of the vertical gel-electrophoresis technique, it has been possible to discriminate a transferrin variant with a mobility very similar to D_1. This variant was originally found in Chinese populations and has been designated $D_{\rm Chi}$ (ref. 4). Kirk, Parker and Bearn[5] re-investigated the transferrin D_1 variants previously reported from different populations to determine whether those transferrin previously classified as D_1 might represent $D_{\rm Chi}$ variants. The $D_{\rm Chi}$ variant was found exclusively in Ceylon, Thailand, north-east India, Malaya, Turk Islands, Formosa, and Japan. Since no transferrin D_1 variants were observed in these areas, it seemed likely that if a transferrin variant occurred in appreciable frequency in Korean populations, it would be of the $D_{\rm Chi}$ type.

Analysis of 120 samples of serum from individuals from Korea disclosed one in heterozygous D variant which proved to be D_1. The occurrence of the D_1 variant in a very low frequency could be ascribed to mutation pressure alone. It will be of interest to examine a larger sample to obtain an accurate estimate of the gene frequency of D_1 in the Korean population and to determine whether the $D_{\rm Chi}$ variant is also present.

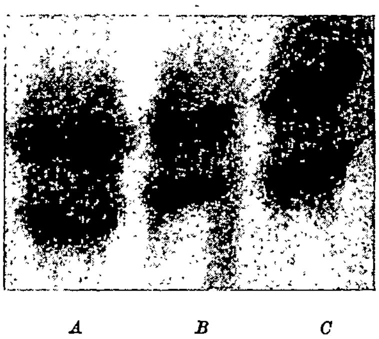

Fig. 1. Comparison of Korean transferrin variant and standard CD_1 and $CD_{\rm Chi}$ by autoradiography after starch-gel electrophoresis. Transferrin C is the faster migrating and transferrin D the slower migrating of the two components. $A = CD_1$, $B = CD_{\rm Chi}$, C = Korean samples (CD_1)

Does a Connexion exist between Blood Group Modifications observed in Leukæmia and Certain Chromosomal Alterations?

A LARGE number of blood group modifications have been observed during the evolution of leukæmias. They belong most often to the ABO system, and can be divided in two classes: (1) In the first group one can classify the cases where a transformation from groups A or B into A weak is observed, or a transformation into group O by a progressive substitution of the substance H, for the substances A or B. (2) In the second group one can classify the cases where the diminution of the antigen A or B is not accompanied by a corresponding increase in substance H, and the cases where, the patient being group O, one assists progressively in the disappearance from his red-cells of the substance H (ref. 1).

As these modifications occur most often in the course of acute myelogenous leukæmias, and as there are strong reasons for believing that the alterations of the chromosomes observed in the leukæmias of this type also affect the erythroblasts, the blood group modifications are perhaps a result of a genetic alteration of the latter.

It is known that the antigens of the ABO system blood group develop from a fundamental substance formed in the erythroblasts[3,4] (Morgan and Watkins, Salmon). This is transformed into substance H by the action of a pair of genes Xx and then the substance H is transformed into substance A by the gene A or into substance B by the gene B. It follows, therefore, that one can consider very schematically that the sum of the antigens A, B and H is constant in the red cell, all development of the antigen A causing a reduction in the quantity of the antigen H, and all diminution of the formation of the antigen A ending in an accumulation of the substance H.

The transformations from group A into A 'weak' might therefore result from a chromosomal alteration located in the locus containing the genes of the ABO system; one could explain this by a damage of one of the chromosomes, which is frequent in the course of certain leukæmias[2]. There are strong reasons in fact for believing that this locus is found on chromosome 21.

The diminutions of substance H or of antigen A not accompanied by a correlative accumulation of substance H can only be explained by a trouble situated on the locus carrying the genes Xx.

Numerous cases of chromosomal aberrations in leukæmias have been published. Unfortunately, in this case the investigation of the blood groups had not been carried out in detail, or revealed nothing abnormal. In one case, however, we have been able to show, in a subject having acute myelogenous leukæmia, constrictions of a pair of chromosomes of group 6–12, and a transformation from the original blood group A_1 by a diminution of the substance A without the corresponding increase of substance H. This allows us to bring up the hypothesis following which the locus Xx is perhaps carried by a chromosome of the medium group.

Numerous observations will still have to be carried out to try to find the exact connexions between the chromosomal malformations of leukæmias and the blood group modifications. Unfortunately, we are as yet only able to explore morphologically the chromosomes; but probably the genetic deficiency is produced on the molecular level. It would therefore be useless to attempt systematically to find it microscopically in all the leukæmias presenting a blood group modification.

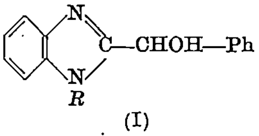
VIROLOGY

Protection of Poliovirus-infected Tissue-culture Cells using the 1-Benzyl, 1-Pentyl and 1-Isopropyl Derivatives of 2-(α-Hydroxybenzyl)-benzimidazole

THE selective protection given by 1-alkyl-2-(α-hydroxybenzyl)-benzimidazoles (I) to *ERK* cells, infected with types 1, 2, and 3 poliovirus, increases from the 1-methyl to the 1-propyl compound, the effect diminishing on passing to the 1-butyl compound[1]. In the case of HBB (I; *R* = H), the D-isomer exerts greater protective action than the DL-isomer[2]. In spite of a disparaging impression of this difference given by the last paragraph of our previous publication[2], the results given therein indicate clearly that protection against types 1, 2 and 3 poliovirus resides largely in the D-isomer. Kadin, Eggers and Tamm[3] have since shown that D-HBB has a greater effect than DL-HBB against the pathogenicity of type 2 poliovirus towards rhesus monkey kidney cells and that L-HBB offers these cells no protection under similar conditions. We have continued our investigation of 1,2-disubstituted benzimidazoles by preparing the 1-pentyl, 1-isopropyl and 1-benzyl derivatives of DL-HBB.



(I)

Table 1. 1-SUBSTITUTED 2-(α-HYDROXYBENZYL)-BENZIMIDAZOLES (I)

R	M.p. (° C)	Yield (%)	Formula	Required (%) C	Required (%) H	Required (%) N	Found (%) C	Found (%) H	Found (%) N
Pentyl	117–8	55	$C_{19}H_{22}N_2O$	77·6	7·5	9·5	77·3	7·8	9·7

Table 2. INFLUENCE OF VARIOUS CONCENTRATIONS OF 1-BENZYL-2-(α-HYDROXYBENZYL)-BENZIMIDAZOLE ON THE ONSET OF CYTOPATHIC EFFECTS IN POLIOVIRUS-INFECTED *ERK* CELLS

Virus type	TCD_{50} units per ml.	Average time (to nearest 0·25 day) between inoculation of cultures and 50 per cent cell degeneration at 37°: Infected controls	HBB (100 μM)	1-Benzyl-HBB 25 μM	30 μM	40 μM	50 μM
1	$10^{6\cdot5}$	0·75	1·0		1·25	1·5	3·5
	$10^{5\cdot5}$	1·0	1·25		3·25	4·0	> 5·0
	$10^{4\cdot5}$	1·5	1·75		4·0	> 5·0	> 5·0
2	$10^{6\cdot5}$	0·75	1·25	2·75	3·5		> 5·0
	$10^{5\cdot5}$	1·25	2·5	4·0	> 5·0		> 5·0
	$10^{4\cdot5}$	1·75	3·75	> 5·0	> 5·0		> 5·0
3	$10^{6\cdot5}$	0·75	1·0		1·25	1·25	1·75
	$10^{5\cdot5}$	1·25	1·5		1·75	2·5	3·0
	$10^{4\cdot5}$	1·75	2·0		2·5	3·5	4·25

Examination of culture tubes ceased on the fifth day and uninfected control cultures were always still healthy on this day.

o-Chloronitrobenzene was condensed with pentylamine and with isopropylamine by the method previously described[1]. *N*-Benzyl-*o*-nitroaniline, m.p. 73°–74°, was prepared in 91 per cent yield by heating *o*-chloronitrobenzene (1 mole) with benzylamine (2·5 moles) at 150° for 5 h, cooling, extracting with water, and crystallizing the residue from ethanol. In each case the substituted *o*-nitroaniline (1 mole) was reduced by hydrogenation and the diamine immediately condensed with mandelic acid (1 mole) in M hydrochloric acid (2·5 moles), following previous procedure[1]. 1-Pentyl- and 1-isopropyl-2-(α-hydroxybenzyl)-benzimidazoles were obtained as white needles and the 1-benzyl derivative as white prisms from aqueous methanol. Yields from this synthesis in Table 1 and in earlier publications[1,2] are based on the substituted *o*-nitroaniline.

Preliminary testing was carried out by measuring the delay in onset of cytopathic change in *ERK* cells after infection with one of the type 1 (*L Sc 2 ab*), type 2 (*P*

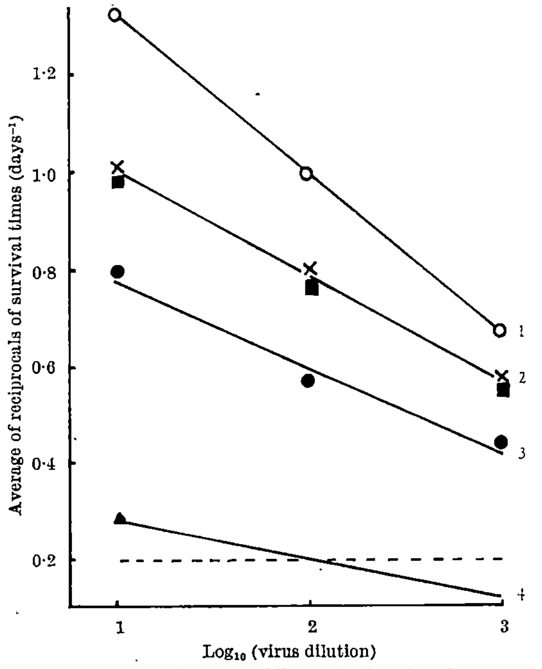

Fig. 1. Lines obtained in assay of the protection given by compounds against cytopathic effects of poliovirus type 1. (1) Control line (test-compounds absent) (○); (2) HBB (100 μM) (×) and also 1-isopropyl-HBB (40 μM) (■); (3) 1-Pentyl-HBB (40 μM) (●); (4) 1-Benzyl-HBB (50 μM) (▲). Examination of cells was terminated on the fifth day after infection. Virus concentration (before dilution) ~$10^{7\cdot5}$ TCD_{50} units per ml.

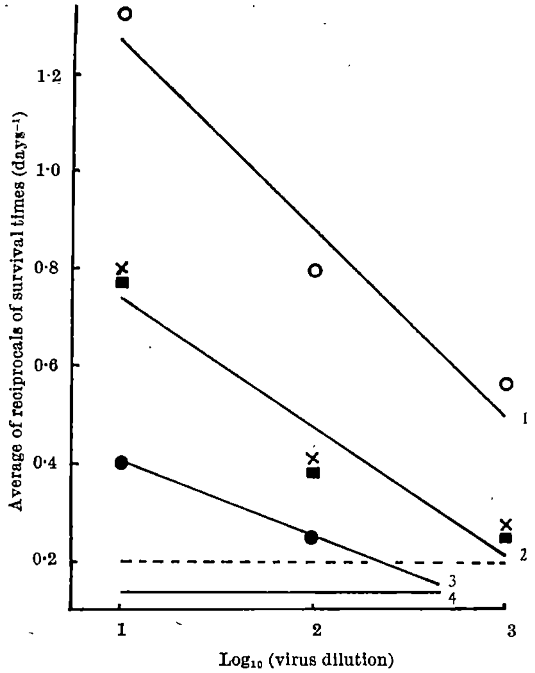

Fig. 2. Protection against cytopathic effects of poliovirus type 2. Legend to Fig. 1 applies, but refers to the type 2 virus

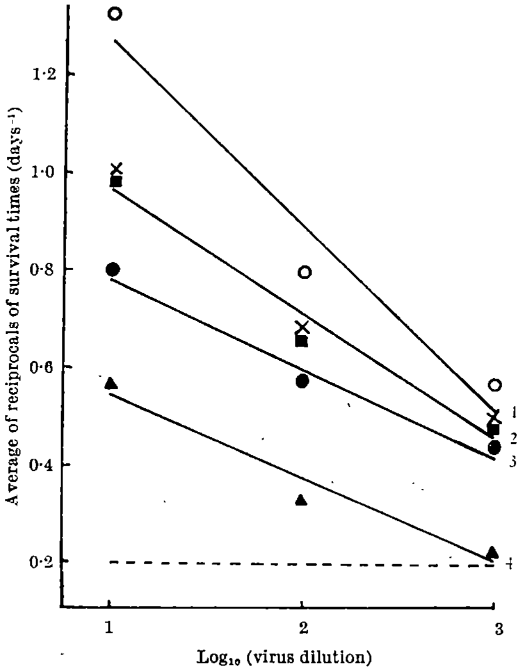

Fig. 3. Protection against cytopathic effects of poliovirus type 3. Legend to Fig. 1 applies, but refers to the type 3 virus

712, *Ch*, 2 *ab*), and type 3 (*Leon* 12 *ab*) viruses using the method previously outlined[1,2]. Results are summarized in Figs. 1, 2 and 3, where protections given by 40 μM 1-isopropyl (line 2), 40 μM 1-pentyl (line 3) and 50 μM 1-benzyl (line 4) derivatives are compared with that given by 100 μM DL-HBB and with infected controls. Plotted points lie on curves, but the functions may be considered to be roughly linear over a restricted range of dilutions. Recent experiments show that 100 μM is the maximum concentration of each of the three 1-substituted compounds that the cells will tolerate and that 210 μM is the maximum tolerated concentration of DL-HBB. Consequently, the relative effects shown in Figs. 1, 2 and 3 need very slight adjustment. The compounds possess no poliovirus-inactivating properties outside the cells. Virus-inhibition and other results will be published elsewhere in due course.

Results presented in Figs. 1, 2 and 3 and the data given in Table 2 indicate that 1-benzyl-2-(α-hydroxybenzyl)-benzimidazole has outstanding performance. The selective protection that it gives to *ERK* cells, against the cytopathic effects of types 1, 2 and 3 poliovirus, approaches that given by the 1-propyl derivative of HBB (PHBB)[1]. The 1-pentyl derivative, while less impressive, still provides noteworthy protection against the types 1, 2 and 3 viruses, while the 1-isopropyl derivative has activity of a similar order to that of DL-HBB itself. We hope to gain more information from study of the 1-isobutyl, 1-phenyl and 1-(α-hydroxybenzyl) derivatives of HBB.

We thank the National Fund for Research into Poliomyelitis and other Crippling Diseases for financial support.

Effect of 5-Fluorouracil on Antigenic Properties of Tobacco Mosaic Virus

Incorporation of 5-fluorouracil (FU) into TMV particles is claimed to exert a number of biological effects. Although the ability to initiate local lesions by equal quantities of normal and FU substituted virus is not significantly different, less virus is produced in a systemic host when substituted TMV is used as the inoculum[1]. Another aspect of FU incorporation is the increased sensitivity of substituted virus towards ultra-violet irradiation[2]. In the last case at least, the biological response could be traced to the altered nucleic acid component of the virus, in analogy to biological systems of higher organization[3,4].

On the other hand, when the protein coat of the FU substituted TMV was analysed, no alterations in the composition of amino-acids could be detected[5]. However, there are no reports on the possible effect of FU on the sequence of amino-acids in the TMV protein, which would have greater bearing on the biological response of such viruses. That such a possibility should be expected could be deduced from work with bacteria[6], where FU, which is known to enter primarily messenger RNA, radically changes the quality of enzymes produced. In this respect a useful criterion regarding the nature of the protein coat of FU–TMV could be the determination of its antigenic properties.

We have already recorded[7] decreased serological activity of partially purified extracts obtained from TMV-infected, FU-treated plant material. In order to determine whether this was solely due to decreased virus multiplication, or also due to altered antigenicity of virus particles, in this report serological activities of standardized preparations of normal and FU-containing virus were examined.

To propagate TMV (isolate 'Mostar'), leaves of *Nicotiana tabacum* var. 'White Barley' were used. Incorporation of FU into virus particles has been described previously[2]. Virus preparations were purified by differential centrifugation and standardized in their concentrations. Two FU containing virus preparations were used, and a non-substituted preparation served as control. Serological micro-reactions were performed in a drop on a microscope

Table 1. SEROLOGICAL ACTIVITIES OF NORMAL AND FU SUBSTITUTED VIRUSES

Virus preparation	Type of micro-serological reaction	Serial dilutions of virus suspensions									
		1	1 : 2	1 : 4	1 : 8	1 : 16	1 : 32	1 : 64	1 : 128	1 : 256	1 : 512
I TMV—FU	On microscopic slide	+	+	+	+	+	+	+	−	−	−
	Under paraffin oil	+	+	+	+	+	+	+	+	−	−
II TMV—FU	On microscopic slide	+	+	+	+	+	+	+	−	−	−
	Under paraffin oil	+	+	+	+	+	+	+	+	−	−
TMV control	On microscopic slide	+	+	+	+	+	+	+	−	−	−
	Under paraffin oil	+	+	+	+	+	+	+	+	−	−

slide, according to the method of Limasset and Augier de Montgremier[8] and Limasset[9], and in a drop under paraffin oil, according to the method of Slogteren[10]. The latter method is characterized by a specific precipitate formed in the drop at the bottom of a Petri dish.

To follow serological reactivity, virus preparations were serially diluted 1 : 2, up to a total dilution of 1 : 1,024. For serological analyses, TMV antiserum, produced in the Laboratory for Flower Bulb Research (Lisse, Holland), was used. From that antiserum, non-specific antibodies were removed by absorption. For controls, normal serum or physiological saline was used.

In Table 1 it can be seen that positive reactions have been obtained up to a dilution 1 : 64, using the first method. No differences between the two substituted virus preparations were evident, and reactivity is the same as in control preparations. The paraffin-oil drop method proved to be more sensitive, and positive reactions were obtained with the same virus preparations with dilutions up to 1 : 128. Again, as may be deduced from Table 1, viruses containing FU showed the same reactivity as control preparations.

These findings, therefore, argue against an effect which FU incorporation might have on the antigenic properties of the TMV coat protein. However, it is still necessary to determine whether the protein coat in the two types of TMV may still not differ in some subtle property.

We thank F. Hoffmann-La Roche Co., Basle, Switzerland, for the generous gift of 5-fluorouracil, and Dr. A. Bećarević for helpful discussion.

PSYCHOLOGY

Ageing and Noise in the Visual System

THE differential visual thresholds of a group of children aged 8–10 years and a group of adults aged 18–22 years have been compared using a technique similar to that used by Gregory and Kendon[1]. Subjects were asked to vary the intensity of a test spot 3 mm in diameter in a field 100 mm long by 25 mm high at a distance of 2·5 m. A series of eight different intensities of the background field was used and each subject was given one series with the background intensity increasing and one series decreasing. The results of these experiments for the two groups of ten subjects are shown in Fig. 1 by plotting ΔI against I, where ΔI is the difference between the intensity of the background and of the test spot for the spot to be correctly located and I is the intensity of the background field. The results of trials with the background intensity increasing and decreasing are pooled, the justification for this being that the same result is achieved by plotting the results from the two series of trials separately. It will be seen that at every level of illumination used the adults had a lower threshold than the children.

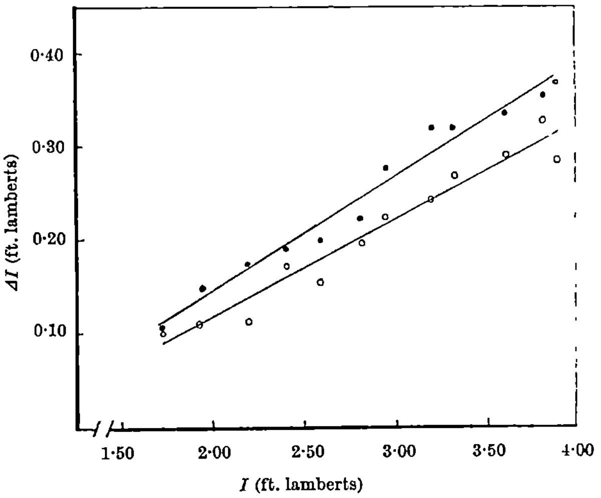

Fig. 1. Data for differential visual thresholds for adults and children. The best fitting line for the two sets of data was found using the method of least squares. ●, Children; ○, adults

It is of interest to compare these results with those of a similar experiment by Gregory and Kendon[1] in which a progressive rise in the slope of ΔI against I was found with age from the 20s to the 70s. Our child subjects seem to have achieved similar results to Gregory and Kendon's older subjects: if we put the two sets of results together it appears that the overall age trend is not progressive but shows a reversal in young adulthood.

It has become customary to attribute such threshold changes with ageing to an increase in neural noise as a person grows older. The treatment of vision as an information source and noisy channel is derived from signal detection theory and when applied to ageing holds that the signal-to-noise ratio diminishes with age. Such an explanation is consistent with two further findings:

(*a*) EEG records of older people tend to show a lowering of general levels of activity and slowing of the dominant rhythms, but some relative rise of what appears to be fairly fast random activity.

(*b*) CFF falls from adulthood onwards. Flicker fusion in these terms can be thought of as occurring at the point at which the difference between peak and trough of illumination is too small to be distinguished. This point will depend on the signal-to-noise ratio in the sense that when this is low the distinction between peak and trough will become blurred. Weale[2] has shown that some, perhaps most, of the fall of CFF during middle and old age can be attributed to alteration of light reaching the retina, that is, to lower signal strength, due to peripheral changes in the eye, but some seem clearly to be due to other causes and may reflect a fall of signal strength or a rise of noise-level in central mechanisms.

These EEG and CFF findings are also true of children who tend to show more fast EEG activity and lower CFF than young adults.

The reasons for decline of signal-to-noise ratio in older people are commonly assumed to be the loss of functional cells which occurs progressively throughout life. The loss would tend to lower signal strength while the lower number of brain cells would mean that there was less averaging of random activity and thus, in effect, a rise of noise-level. It has also been suggested that shortly before destruction nerve cells tend to show an increase of spontaneous activity, which would constitute a form of noise in the nervous system.

Clearly these explanations cannot apply to children. Any explanation of the similarity between older adults and children in this matter must be speculative, but a possible reason might be that, as suggested by Hebb, there is an increased patterning during childhood of the connexions between nerve cells, and that this patterning results in an effective increase in the number of discrete functional units.

Falling Efficiency at Sorting Cards during Acclimatization at 19,000 ft.

DURING the course of the Himalayan Scientific and Mountaineering Expedition 1960–61 (ref. 1) the members sorted cards three times, a practice at a height not much above sea-level, and then two tests at 19,000 ft. Before the first test the average stay at 19,000 ft. had been 2 weeks, with an additional 6 weeks at 15,000 ft. Between the two tests an additional average of 9 weeks had been spent at 19,000 ft., plus 2 weeks at 15,000 ft. Adequate data were available for only three members of the expedition, whose ages ranged from 23 to 32 years. A comparable group of eleven research scientists from the Applied Psychology Research Unit was therefore collected, covering the same range of ages and academic experience. These men sorted cards with the same card-sorter three times in Cambridge, separated by the same average time-intervals. Table 1 shows that the number of delayed responses increased after acclimatization at 19,000 ft., whereas it fell slightly at about sea-level.

Table 1

Height above sea-level (ft.)		Age (years)	Mean percentage of delayed responses		
			Test 1	Test 2	Difference
19,000	J. B. W.	32	2·66	2·87	0·21
	J. S. M.	30	2·86	4·95	2·09
	M. B. G.	23	2·04	3·48	1·44
	Mean of 3 men	28	2·52	3·77	1·25*
< 50	Mean of 11 men	30	3·07	2·83	−0·24*

* Two groups reliably different ($P < 0.05$ on a two-tailed Mann–Whitney U test (ref. 3)).

Each man had to sort packs of cards continuously for 30 min into boxes according to suit. The time at which each card fell into a box was recorded automatically on magnetic tape. A fuller description of the apparatus is given in Poulton *et al.*[2]. The errors of classification, which averaged about 4 per test in the two tests both at 19,000 ft. and at about sea-level, were recorded by the experimenter. To be counted as delayed, the recorded time-interval between a response and the previous response had to exceed 2·0 sec. The increase in the percentage of delayed responses at 19,000 ft. was reliably greater than the change in the control group at sea-level; a difference in mean rank order as large as that between the two groups would have occurred by chance less often than once in 20 experiments[3].

So far as we know this is the first time that a statistically reliable change in performance has been reported in men during acclimatization at such heights. That the change was for the worse is compatible with the observation that "all members of the party lost weight at a rate of 1–3 lb. (0·45–1·36 kg) a week at 19,000 ft. (5,790 m)" (ref. 1). Previous work on acclimatization to height has simply compared the performance of men at different heights up to 17,500 ft. after they had become acclimatized to that height[4,5].

The tape-recordings from the experimental and control groups were made in different places at different times, and any discrepancies which could have been produced in this way inevitably confound the differences reported between the two groups. By comparing the differences for each individual between tests 1 and 2, this criticism has been taken care of as far as it is possible to do so, since any constant added to the results of both tests 1 and 2 will have been eliminated. But the effect of a constant multiplier, if present, has not been eliminated. The possibility of an artefact is difficult to rule out completely when comparing the course of acclimatization in a remote but natural environment with the effect of time alone on a control group.

A second task, number checking, showed no reliable change in performance over that of the control group until a height of 24,400 ft. was reached. This was presumably due to the insensitivity of the task[6], since reliable changes in performance on many tasks are recorded at heights above 10,000–15,000 ft.[7].

This work was carried out under the direction of Dr. L. G. C. E. Pugh and Mr. D. E. Broadbent. We also thank Dr. J. A. Leonard for help in designing the card sorter, the members of the Expedition and of the Applied Psychology Research Unit for acting as experimental subjects, and the Medical Research Council for financial support.

FORTHCOMING EVENTS

Tuesday, July 28

Society for Analytical Chemistry, Physical Methods Group (joint meeting with the Polarographic Society, at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Dr. Dale J. Fisher (Oak Ridge National Laboratory, Tennessee): "Controlled Potential D.C. Polarography".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Research Officer (male) for work on helminths of economically important marine fish—The Director, Commonwealth Bureau of Helminthology, The White House, 103 St. Peter's Street, St. Albans, Hertfordshire (July 30).

Lecturer (botanist specializing in biochemistry or biochemist) in Botany—The Registrar, The University, Manchester 13 (July 31).

Lecturer (with a good honours degree, and teaching and/or research experience in one or more of the fields of general, social, occupational or experimental psychology) in Psychology in the Faculty of Social Studies, University of Nigeria, Nsukka, Eastern Nigeria—The London Representative, University of Nigeria, 33 Craven Terrace, London, W.2 (July 31).

Mathematician or Scientist (not under 26 years of age, with at least a second-class honours degree or equivalent, and three or more years' postgraduate research experience) in the Radiobiological Protection Division of the United Kingdom Atomic Energy Authority Health and Safety Branch, to apply mathematical techniques to biological problems—The Administration Officer, U.K.A.E.A., Health and Safety Branch, Harwell, Didcot, Berkshire, quoting Ref. H.35/J14 (July 31).

Research Assistant and a Research Student in the Department of Medical Physics, to work on the absorption of ionizing particles in liquids—Prof. H. A. B. Simons, Royal Free Hospital School of Medicine (University of London), 8 Hunter Street, London, W.C.1 (July 31).

Research Assistant (Computer Programming) (with a university degree with mathematics as either a main or subsidiary subject) in Statistical Ecology in the Department of Botany, for work concerned with the preparation and running of computer programmes for the statistical analysis of vegetation by multivariate methods—The Secretary and Registrar, The University, Southampton (July 31).

Assistant Lecturer, Grade "B" (qualified pharmacist, biochemist or biologist) in Applied Biology in the Department of Science—The Principal, Coventry Technical College, Butts, Coventry, marking envelope "application" (August 1).

Research Assistant (with an honours degree in physics or equivalent qualification and some research experience) in Physics to work on nuclear magnetic resonance in liquid metals and alloys—The Registrar, The University, Sheffield (August 1).

Theoretical Physical Chemist (honours graduate, preferably with Ph.D., and previous experience in the mathematical treatment of physicochemical systems), to study the theoretical aspects of the micropore structure/gas absorption of porous carbons—The Assistant Secretary, Ref. A.5, The British Coal Utilization Research Association, Leatherhead, Surrey (August 1).

Departmental Graduate Assistant in the Department of Physics to work in the field of geophysical hydrodynamics and magneto-hydrodynamics—The Registrar, The University, Newcastle on Tyne, 2 (August 7).

Lecturer or Senior Lecturer (with a higher degree in zoology, evidence of competence and interest in research in a field of vertebrate zoology (preferably ecological or behavioural studies), and experience in university teaching) in Zoology at the University of Queensland, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Brisbane and London, August 7).

Assistant Lecturer or Lecturer in the Department of Genetics to teach the genetics of micro-organisms—The Registrar, The University, Liverpool, quoting Ref. CV/24 (August 8).

Assistant Lecturer (with an honours degree in pharmacy and preferably specialized in pharmacognosy, and an interest in phytochemistry) in Pharmacy—The Registrar, The University, Manchester, 13 (August 8).

Lecturer in Biochemistry—The Secretary, Royal Free Hospital School of Medicine (University of London), 8 Hunter Street, London, W.C.1 (August 8).

Principal Electronics Engineer (physicist/engineer) to take charge of part of the programme of development of fishing vessels and their equipment—The Technical Director, White Fish Authority, Industrial Development Unit, Saint Andrew's Dock, Hull, East Yorkshire (August 8).

Research Fellow (with at least a Ph.D. degree in chemistry or biochemistry) in the Division of Forest Products, Commonwealth Scientific and Industrial Research Organization, South Melbourne, Victoria, Australia, to participate in a programme concerned with the polyphenolic extractives and exudates of wood, their influence on the properties of wood, and also with the various factors controlling the formation of these substances by the tree—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 290/697 (August 8).

Lecturer in Fuel Technology and Chemical Engineering—The Registrar, The University, Sheffield (August 10).

Lecturer in Sociology or Anthropology; and a Lecturer in Social Psychology at Makerere University College, Uganda—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (August 14).

Physicist (with a good degree and interest in agricultural meteorology and preferably some research experience) for work on water use by plants and the effects of light on plant growth—The Secretary, Rothamsted Experimental Station, Harpenden, Hertfordshire (August 15).

Research Fellow (with a Ph.D. in metallurgy or physics or equivalent qualifications together with some research experience in physical metallurgy or metal physics, and preferably experience with modern electron microscopic or X-ray crystallographic methods) in a newly established D.S.I.R. Research Group on the structure and properties of alloy steels, under the direction of Professor of Physical Metallurgy—The Registrar, The University, Sheffield (August 15).

Tutorial Assistant; and Research Assistants (2) in the Department of Geology—The Registrar, University College of Wales, Aberystwyth (August 15).

Lecturer (Clinical) in the Department of Pathology—The Assistant Registrar, Medical School, The University, Birmingham, 15 (August 17).

M. C. Smith Lecturer in Pathology (Cancer Research)—The Assistant Registrar, Medical School, The University, Birmingham, 15 (August 17).

Senior Lecturer in Civil Engineering—The Registrar, The University, Sheffield (August 17).

Assistant Lecturer or Lecturer in Biochemistry—The Dean, Guy's Hospital Medical School, London Bridge, London, S.E.1 (August 18).

Reader (with a record of scholarship in the field of experimental psychology) in Psychology—The Registrar, The University, Hull (August 22).

D.S.I.R. Research Assistant (physical chemist preferably with research experience of reaction kinetics and/or solid state measurements), to work on a research project concerned with the solid state properties of carbon in relation to catalytic activity—The Secretary, Queen's College (University of St. Andrews), Dundee, Scotland (August 24).

Lecturer in Physics at the University of Sydney, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, August 28).

Assistant Librarians (2) (graduates with university library experience and/or professional qualifications)—The Registrar, The University, Sheffield (August 29).

Assistant Keeper (with some training and an interest in taxonomy, preferably in that of cryptogamic plants) in Botany at the Manchester Museum—The Registrar, The University, Manchester, 13 (August 31).

Senior Research Officer (with a special knowledge, preferably with research experience, in some branch of numerical or non-numerical analysis)—The Director, University Computing Laboratory, 9 South Parks Road, Oxford (August 31).

Public Analyst (Fellow of the Royal Institute of Chemistry with the Branch E Certificate or Diploma) for the City of Southampton—The Town Clerk, Civic Centre, Southampton (September 1).

Lecturers/Senior Lecturers (2) (graduates in medicine, science or veterinary science of honours standard or equivalent, with appropriate teaching and research experience in physiology) in the School of Physiology, The University of New South Wales—The Agent General for New South Wales, 56–57 Strand, London, W.C.2; and The Appointments Section, University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia (September 4).

Senior Lecturer or Lecturer in Microbial or Molecular Genetics; and a Senior Lecturer or Lecturer in Comparative or Cellular Physiology in the Department of Zoology, University of Melbourne—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1; or The Registrar, University of Melbourne, Parkville, N.2, Victoria, Australia (Australia, September 15).

University Lecturer (with evidence of ability and experience in teaching or research in animal nutrition, and preferably an interest in ruminant nutrition) in Animal Nutrition—The Secretary, University of Cambridge School of Agriculture, Cambridge (September 15).

Chair of Biochemistry—The Registrar, University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne, 2 (September 26).

Second Chair of Physics at the University of Canterbury, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and New Zealand, September 30).

Chair of Electrical Engineering—The Secretary, The Queen's University, Belfast, Northern Ireland (October 10).

Chair of Organic Chemistry at the University of Adelaide, South Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.7 (Australia, October 31).

Assistant Lecturer (suitably qualified metallurgist or mechanical engineer, preferably with research experience) in the Metallurgy Department—Prof. A. V. Bradshaw, Royal School of Mines, Prince Consort Road, London, S.W.7.

Assistant Lecturer (with qualifications in physics, chemistry and chemical engineering together with three years' research experience) in the Department of Chemical Engineering and Chemical Technology, to work in the field of transport properties at high pressures—Head of the Department of Chemical Engineering and Chemical Technology, Imperial College of Science and Technology, London, S.W.7.

Gassiot Research Fellows at the Meteorological Office, one for research in seismology and the other for research in geomagnetism—The Secretary, Meteorological Office, London Road, Bracknell, Berkshire.

Head (with high academic qualifications and a substantial combination of teaching, research and industrial experience) of the Department of Chemistry—The Academic Registrar, Brunel College, Woodlands Avenue, Acton, London, W.3.

Immunologist (national of the United Kingdom or the Republic of Ireland, with a good honours degree in zoology or microbiology or a registrable qualification in veterinary science, and some laboratory experience preferably in the immunological field) at the Veterinary Research Laboratories, Kabete, Kenya, to investigate problems of artificial immunity to trypanosomiasis in livestock; duties may also include studies on the bionomics of the vector tsetse flies—The Department of Technical Co-operation, Room 301, Eland House, Stag Place, London, S.W.1, quoting Ref. RC217/95/07.

Junior Technical Officer (with at least G.C.E. at "A" level in two science subjects, including one in a biological subject, if below the age of 22, or a pass degree for age 22 and over) in a Group working on mouse genetics—The Administrator, Radiobiological Research Unit, Medical Research Council, Harwell, Didcot, Berkshire, quoting Ref. MFL/3.

Lecturer in the Department of Metallurgy to lecture and to carry out research in physical metallurgy—The Registrar, The University, Liverpool, quoting Ref. CV/242/N (September 19).

Lecturer/Assistant Lecturer in Chemical Engineering, to take a particular interest in process control—The Secretary and Registrar, Bristol College of Science and Technology, Ashley Down, Bristol, 7, quoting Ref. CST 64/73.

Lecturer in Physical Chemistry for duties in the B.Sc. Special Chemistry and B.Sc. General courses—Clerk to the Governing Body, Northern Polytechnic, Holloway, London, N.7.

Lecturer in the Applied Physics Section to teach general physics and research in photoelectronics, vacuum physics, etc.—Prof. J. D. McGee, Physics Department, Imperial College of Science and Technology, London, S.W.7.

Lecturer or Assistant Lecturer in Geography—The Secretary, Sir John Cass College, Jewry Street, London, E.C.3.

Marine Biologist (with an honours degree in natural science, preferably in biology or zoology, and one year's postgraduate experience in appropriate research work, preferably in fisheries research or work of value in marine biology) at Hong Kong, to investigate and control invertebrates and minute organisms of marine life and their ancillary problems which would normally arise as a result of the changeover of a salt-water lake to fresh-water—The Appointments Officer, Room 301, Department of Technical Co-operation, Eland House, Stag Place, London, S.W.1, quoting Ref. RC.289/81/01.

MUSEUM TECHNICIAN (man or woman with experience in the preparation and arrangement of zoological material for museum display)—The Professor of Zoology, The University, Hull.

POST-DOCTORAL FELLOW for work on the chemistry of epimino-sugars—Dr. R. D. Guthrie, The Chemical Laboratory, University of Sussex, Brighton, Sussex.

RESEARCH ASSISTANT (recent graduate or graduating this year Hons.B.Sc, in biochemistry, physiology or veterinary science) to Dr. W. J. O'Connor. Department of Physiology, to study water and sodium balance of dogs—Dr. W. J. O'Connor, Reader in Renal Physiology, Department of Physiology, Medical School, The University, Leeds, 2.

RESEARCH OFFICER (Entomologist) (national of, and permanently resident in, Great Britain or the Republic of Ireland, with an honours degree in biology and appropriate postgraduate experience) with the East African Common Services Organization, to plan and carry out research on the biology of Malaria-carrying mosquitoes in East Africa, and to direct field and Laboratory work of an established entomological research team—The Department of Technical Co-operation, Room 404, Eland House, Stag Place, Victoria, London, S.W.1, quoting Ref. No. RC205/173/02.

RESEARCH STUDENTS (2) (with a good honours degree in geology) IN THE DEPARTMENT OF GEOLOGY—Head of the Department of Geology, Chelsea College of Science and Technology, Manresa Road, London, S.W.3.

SENIOR CHEMIST in the Division of Biochemistry, The Laboratories, Belfast City Hospital, for duties which will include the supervision of routine investigations and the development of new analytical procedures—The Group Secretary, South Belfast Hospital Management Committee, Belfast City Hospital, Belfast 9, Northern Ireland.

VERTEBRATE PALAEONTOLOGIST IN THE DEPARTMENTS OF GEOLOGY AND ZOOLOGY with duties in teaching and research—Head of either the Department of Geology or the Department of Zoology, University of Alberta, Edmonton, Alberta, Canada.

TOWARDS A POLICY FOR TECHNICAL CO-OPERATION

ONE reason given in the Plowden Report for the changes recommended in the organization of the Services representing Britain overseas is the increasing importance of the duties which these Services have now acquired in connexion with giving British aid and the administration of technical assistance abroad. Again, while Prof. P. M. S. Blackett did not suggest that technical aid was a reason for expanding our universities in his Granada Lecture in October 1963, he did point out that such expansion would enable Britain to play a much more vigorous part in assisting the progress and welfare of the new and emerging nations, and he instanced three ways in which Britain could help. Two of these directly concerned the universities—the provision of academic and other professional staff on secondment at request, and the provision of wider training facilities in Britain's universities, especially postgraduate. In recent debates in the House of Lords on the problem of leisure and on the Newsom Report, reference was made to the importance of Voluntary Service Overseas, both from this point of view of technical aid and from that of affording opportunity for expression of the altruism of youth.

In view of this widespread interest in technical aid, both as such and from varying points of view, particular interest attaches to the various publications of the Overseas Development Institute. One such recent publication, *Colonial Development*[*], completes the Institute's factual survey of British aid to developing countries, of which four pamphlets have already appeared. A second recent publication, *Not by Government Alone*[†], reviews the work of voluntary organizations participating in the Development Decade. In a third, *French Aid: the Jeanneney Report*[‡], the Institute provides a convenient abridged translation of the report of the Jeanneney Commission set up by the French Government in 1963 to examine independently the whole problem of French aid to the developing countries, its justification, its aims and its administration.

France at present devotes nearly 2 per cent of her national income to aid for the developing countries, and the total of £350 million in 1962 is more than twice Britain's contribution. Because this figure helps to put the subject in a better perspective and also because this Report on the politics of co-operation is a major recommendation on policy for one of the chief donors of aid and is likely to be treated as a basic document by French Governments for some time to come, it seems useful to consider the January Report first. A small section of it, mainly concerned with administration, was regarded as confidential by the French Government and was not published. For the rest, the Report is a logical and cogently argued document, reviewing first, in an introduction, the conditions of economic development, the possible contributions by developed countries, and the principles of action. Next, in successive chapters, the reasons for aid are analysed, the resources available reviewed, and finally the distribution and forms of aid are considered.

There is much more that is of general interest in the Report, as its proposals are not narrowly conceived and mostly bear consideration by other countries, though it is unlikely that all its suggestions and analyses will command general acceptance. They should, at the least, stimulate some hard thinking about Britain's own programme of aid and the structure and work of the Department of Technical Co-operation. It is recommended, for example, that 25 per cent of French aid should go through multilateral channels, and a critical look at individual proposals is urged: some of the present aid may be expensive to the aiding country but contribute little or nothing to the aided country. Again, developing countries should not be expected to model themselves on the aiding country except in so far as the structures copied favour their development. Nor should aid to countries which are temporarily poor be regarded as a short-term relief. It should form part of a new conception of the economic relations between unequally developed countries, firmly based on contractual arrangements. Even the sacrifices involved in trade adjustments would, in the long run, be less heavy than aid in traditional forms, and they would be more effective for the development of countries whom it is desired to help,

There are some points in the Jeanneney Report which should be noted particularly by scientists in Britain. Prof. Blackett's plea for more help in research is fully supported by the observation that, in science and technology, developed countries can not only help by making their knowledge available to developing countries but also by research in fields that are useful, particularly if the developing countries are associated with such research. No estimate is given of the extent to which either manpower or financial resources at present committed to technical assistance is engaged in research. However, of 46,000 people at present provided by France, nearly 32,000 are teachers and only some 1,000 are regarded as real experts on an international level. Provision of teachers is recognized as one of the most valuable forms of aid, but, nevertheless, the Report insists that in developing countries education must be useful for development: the training offered in the advanced countries should be considered only in the light of the contribution its beneficiaries can make to the development of their country when they return.

A similar pragmatic note is struck in respect of specialists from developed countries in the comment that their duty to prepare for their replacement by local people is less often adequately performed than their contribution to the smooth working of enterprises or public services. There are also firm reminders that if experts of the desired quality are to be recruited for this purpose, proper attention must be directed to arrangements for their remuneration, including not only the scale of salary, etc., but also its security, and to their careers on return to France. It is suggested that French policy should encourage the activities of the numerous societies and institutes in France, particularly those concerned with agricultural and industrial techniques, the work of which can be valuable for developing countries. Reference is made to the openings for consultants; it is suggested that it would be useful to establish a set of rules for correct practices and then to keep a list of consultants prepared to adhere to the rules and capable of doing so.

---

[*] Overseas Development Institute, Ltd. British Aid—5: *Colonial Development—a Factual Survey of the Origins and History of British Aid to Developing Countries*. By D. J. Morgan. Pp. 96. (London: The Overseas Development Institute, Ltd., 1964.) 7*s*. 6*d*.

[†] Overseas Development Institute, Ltd. *Not by Governments Alone: The Role of British Non-Government Organizations in the Development Decade*. By Peter Williams and Adrian Moyes. Pp. 51. (London: Overseas Development Institute, Ltd., 1964.) 3*s*. 6*d*.

[‡] Overseas Development Institute, Ltd. *French Aid: The Jeanneney Report*. (An abridged translation of "La Politique de Coopération avec les Pays en Voie de Développement".) Pp. 51. (London: Overseas Development Institute, Ltd., 1964.) 5*s*.

In view of the comments of the Plowden Committee on the work of scientific attachés, it is interesting to note that the Jeanneney Commission believes that scientific representation is generally inadequate in French diplomatic missions in spite of the considerable opportunities in many countries open to scientific attachés. Not only competent to organize exchanges in higher education and research, supervise documentation centres and ensure that more space is given in the foreign Press to French science and technique, the scientific attaché should at least be able to talk on equal terms with the scientists of the country to which he is accredited, and should be closely in touch with travelling French scientists. While the Jeanneney Commission proposes some expansion in the number of scientific attachés and the Plowden Committee thought that for Britain the present number was about right, the two reports agree substantially as to the duties of such attachés. Much like the Plowden Report, the Jeanneney Report contemplates the appointment of some leading research workers as French representatives abroad, for some 3–6 months.

Emphasis is placed on the value of allocating aid funds to the supply of French books to university centres and libraries, and besides suggesting that currency losses on books sold commercially in countries where currency is not convertible should be balanced, it is also proposed that books of a suitable kind and price should be specially prepared for developing countries. This obviously follows the general lines of the scheme already adopted by Britain, but one other feature of the Jeanneney Report that should be welcomed as well as noted is the forthright views expressed on principles of action. While the importance of sincere acceptance of the independence of the developing countries could not be more clearly expressed, it is never suggested that respect for such independence means that the aiding country must ignore what it believes to be wrong in the aided country. The Report is certainly as frank as an earlier Political and Economic Planning Broadsheet on the importance of political stability, and of appropriate political régimes and efficient administration in the aided countries.

This statement of principles merits consideration in any discussion of Britain's programme of technical aid or of the activities of such bodies as the Commonwealth Development Corporation. Avoidance of excessive economic integration, for example, certainly makes it easier to resolve disputes with calmness and objectivity, though it does not necessarily ensure success. The search for well-adapted political structures should be supported and it is welcome to find this condemnation of dogmatic support for particular political forms and reminder that neither capitalism nor communism may be suited to developing countries. Above all, procedures are needed to give protection against the effects of domination, and, in urging efforts to discover such procedures, the Report suggests that as a start States with geographical, historical or cultural affinities might make agreements covering such points as: the distribution among the signatories of the burden and benefits of aid: an undertaking by the rich countries to devote a certain percentage of their material product to co-operation and by the recipient countries to devote a percentage of their own material product to investment; the taxation of foreign enterprises in developing countries; the regulation of labour disputes in foreign enterprises; procedures for avoiding the allocation of aid to investments which would duplicate others in the same part of the world; and the conditions in which countries could nationalize enterprises on their territory, the rules and manner of indemnification.

The enumeration of general principles in such matters might facilitate the building up of more durable relation and should promote the confidence which would promote the most efficient supply and utilization of resources. Something on these lines is clearly needed, and the Jeanneney Report demonstrates the existence of a certain amount of thinking on similar lines in different countries. Similarly, the review of British non-government organizations made by P. Williams and A. Moyes for the Overseas Development Institute shows a surprising range of voluntary organizations participating in the supply of unofficial aid to the developing countries. In scale, this probably reaches more than £15 million a year, apart from the £150 million a year which British private firms are thought to be investing in less-developed countries and probably supports about 6,000 British workers in developing countries. This compares with the present £150 million provided by the British Government in loans, grants, investments and technical assistance to developing countries, mostly within the Commonwealth and covering the salaries, in part or in full, of about 16,000 British experts and teachers in developing countries and awards to about 3,000 students and trainees in Britain.

The review is in two parts: a survey of opportunities which includes some suggestions for realizing them, is followed by a factual account of non-government organizations concerned with helping developing countries. Commercial organizations are not discussed, and an introduction explains the challenge of both Governments and private organizations for constructive thinking thrown down by the resolution in the General Assembly of the United Nations last December. Sponsored by the United Kingdom Government and fourteen others, that resolution called for participation by non-government organizations in a world campaign 1965–70 to help developing countries in the fields of food, health and education. The resolution was adopted unanimously and it represents a continuing challenge to Governments to intensify and expand official aid programmes and a new challenge to non-government organizations to become involved in world development to a greater extent.

Government aid depends on the co-operation of non-government organizations for the provision of a large part of the resources, particularly for technical assistance and also for engendering public understanding and support for the aid programme. The relatively favourable climate of public opinion in Britain towards helping developing countries is largely due to non-government organizations; however, the pamphlet suggests that the variety of organizations and aims—more than a hundred are listed in the pamphlet, but the total runs into hundreds—confuse the public, and it is urged that these non-government bodies should present a clearer image o their pattern and activities to the public. They also need greater resources and they should enter into a close working partnership with the Government.

Some thought must be given to the proper role, aims and objectives of British non-government organizations, the means of achieving them and the dovetailing of these activities into national and international effort to assist overseas development. A need is shown for some national association in which the main non-government organizations would all be represented, but covering a wider field than the Freedom from Hunger Campaign or the Standing Conference on Voluntary Organizations Co-operating in Overseas Social Service. Such an association would have as its major task the job of showing how the activities of these bodies were related to each other and to the Government's aid programme. The problem of increasing the financial resources of the voluntary bodies is more difficult and some of them may find the criticism of this booklet, well founded and moderate as it is, hard to accept. None the less, the problem must be faced, and the booklet is equally clear as to the danger of excessive dependence of aid on Government support. Something of the value of Voluntary Service Overseas could well be lost as the Department of Technical Co-operation becomes responsible for financing 75 per cent of British volunteers. It is interesting, if unexpected, to find in this extent of financial support a plea for extended support by the Government of overseas research, though it is not clear whether what is in mind is research conducted for overseas countries in British research institutions or research in overseas institutions.

The possibilities and opportunities as well as the degree of failing to achieve a fitting balance of effort between the private and independent bodies and the Government's own official programme of technical aid are clearly displayed and the booklet should be studied by the Department of Technical Co-operation as well as by the voluntary organizations themselves. The third of the three pamphlets, and that which completes the factual survey of British aid by the Overseas Development Institute, sets the whole subject against the background of colonial development from the Act of 1929 and the Colonial Development and Welfare Acts from 1940 onwards. Indeed, Er. D. J. Morgan provides an admirable and lucid summary of the origins and history of British aid in the light of Britain's relations with the colonies during the past half-century. Successive chapters review assistance to the colonies first up to and then after 1945, while shorter chapters are given to the subjects of sterling balances, colonial currency systems, and aspects of Commonwealth trading.

In a final chapter, "General Conclusions", Mr. Morgan raises some questions about the future aid programme now that the main problem is that of aid in relation to independent countries of the Commonwealth and then outside the Commonwealth. So far as the smaller territories are concerned, Mr. Morgan questions whether past criteria should continue to be applied and past methods used in assisting territories like St. Helena, or whether their organization and treatment might not be better assimilated to that of, for example, the Highlands of Scotland. Again, he suggests that aid should be extended to the independent Commonwealth, but rather under such a system of supervision as the Colonial Development and Welfare system provides, though he points out that the Committee of Public Accounts is scarcely appropriate for the new situation. For those independent countries of the Commonwealth that are unable to balance their budgets without grants, he advances the tentative suggestion that Britain might accept financial responsibility for some such public service, such as elementary education or agricultural development for a term of years, possibly with a system of block grants.

Here again is a challenge to some hard thinking which may well involve a fresh look at the structure and responsibilities of the Department of Technical Co-operation. Furthermore, the note of urgency is again sounded, and this is further attested by the latest report from the Commonwealth Development Corporation, which once again stresses the inadequacy of the financial margin on which the Corporation is called on to work. Apart from this, the continuing demand for the services of the Corporation not only shows that its work is fully appreciated overseas but indicates also that the scope of its activities should fittingly be reconsidered in the light of the comments made in Mr. Morgan's survey of colonial development, especially in the independent countries. There is no reason to doubt the imagination or the human understanding which Mr. Robert Carr brings to his task as Secretary for Technical Co-operation. What is in doubt is whether he is receiving the support from the Government as a whole that the urgency and importance of his work demand. The three pamphlets noted should leave the Government in no doubt as to that urgency and importance; used with wisdom and energy they could also do much to promote the public understanding that would compel adequate support from any Government.

EXPLORERS OF ARABIA

Arabia Felix

The Danish Expedition of 1761–1767. By Thorkild Hansen. Translated by James and Kathleen McFarlane. Pp. 381. (London: Collins, 1964.) 30*s*.

ARABIA FELIX describes the adventures of the first expedition to undertake scientific exploration in Arabia, which was despatched from Denmark in 1761 and included the great Swedish botanist Forsskål among its members. Only one of them, the surveyor Carsten Niebuhr, lived to return to Europe in 1767. His *Beschreibung von Arabien* and *Reisebeschreibung nach Arabien und andern umliegenden Ländern* are among the classics of oriental travel. The author of the present narrative is a Danish literary critic and translator of modern French literature, who has himself travelled in Saudi Arabia and the Sudan. It is decidedly popular in style. In emphatic contrast to Niebuhr's works, it accords prominence to personal relations, jealousies, and the quarrels of the travellers. Space is even wasted in telling the reader what they "must have" thought or felt, sometimes even "half-consciously". Mr. Hansen has, however, consulted unpublished material in the Danish State Archives and has used a number of books that are available only in Scandinavian languages. There is thus some information that will be new to most British readers. The translation is smooth, the plates, nearly all taken from Niebuhr's books, have been well chosen, and the index is adequate, though a more detailed map would have been welcome.

There are some sensible comments, as, for example, on the meagre achievements of the orientalist of the expedition, von Haven. To state, however, that "the concept of colonial expansion was still thought of as implying only a question of which European country was to control these foreign peoples" is to ascribe to these men the assumptions of a later age. In 1762 a colony was, in Dr. Johnson's definition, "a body of people drawn from the mother country to inhabit some distant place". Before the spectacular successes of the Russians in the war of 1768–74 against the Turks, there was no likelihood that large numbers of Ottoman subjects would pass under European rule, least of all in the Asiatic provinces. This is an unfortunate error. Niebuhr's freedom from such presuppositions was one of his great advantages over many subsequent explorers. "In a Dane of the middle of the eighteenth century," wrote D. G. Hogarth sixty years ago in his *Penetration of Arabia*, "the sense of western and racial superiority was not developed enough to debar him from full sympathy with an eastern people. Niebuhr did not see in the Yemen Arabs an interesting lower order of beings, nor in their creed and religious practices curious parodies of those of a Christian".

The author is also wrong in supposing that to travel in Arab dress was then "most unusual for Europeans in the Orient". There were many parts of Asia where very few Europeans penetrated at all, but those who did could often not have travelled in any other way. There are a few mistakes. W. B. Harris should not be called a great English explorer, and his book was not entitled merely *Yemen*, but *A Journey through the Yemen*. Mr. Hansen's "Captain Pasha, the pirate" was the Kapudan Pasha, the imperial Ottoman admiral, as Niebuhr himself says. The "village of Abb" is Niebuhr's town ('Stadt', not 'Dorf') of Äbb; it is the modern Ibb. There is regrettable, though understandable, confusion in the spelling of oriental place names. In his own books Niebuhr used 'sch' and 'dsj' for the sounds usually represented in English by 'sh' and 'j' respectively. His 'Scherdsje' and 'Mauschid' would be confusing enough for British readers, but here they become 'Sjerdsje' and 'Mausjid'. 'Sherje' and 'Maushid' would have been preferable. There are too many misprints in proper names, Palsgrave for Palgrave, Charden for Chardin, and Hodeia consistently for Hodeida.

These, however, are comparatively unimportant blemishes in a readable and pleasantly produced volume which will interest anyone who wishes to know more about the personalities of Niebuhr, Forsskål, and their companions and the background of this astonishing expedition. Naturally, there is much more about Niebuhr than the others, but there is nothing here to make one doubt the justice of Hogarth's memorable judgement, that "if he was not the most brilliant of the party, if any of his fellows surpassed him in energy, courage, and endurance, in intelligence, or in his measure of that scientific temper which is equally free from prejudice and from laxity, then a more remarkable mission was never despatched to any land". C. F. BECKINGHAM

ADVANCES IN ANALYTICAL CHEMISTRY

Advances in Analytical Chemistry and Instrumentation

Vol. 2. Edited by Charles N. Reilley. Pp. vii + 408. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, Inc., 1963.) 115*s*.

THIS volume continues a series in which new ideas and instrumental techniques in analytical chemistry, together with developments in more classical methods, are reviewed by practical experts of international repute. The editor has again secured the services of a distinguished group of contributors and the generally high standard of the individual articles is therefore to be expected, but the volume as a whole might have benefited from a little more uniformity in the treatment of the various subjects.

For example, F. Feigl, R. Belcher and W. I. Stephen, reviewing "Progress in Qualitative Organic Analysis", have compressed this vast subject into 29 pages of text, the result being virtually a catalogue of the significant papers published during the past ten years, in the style of the Chemical Society's *Annual Reports*. On the other hand, G. Mattock has filled 81 pages with a detailed discussion of laboratory pH measurement, including such useful data as a table for the location of faults in glass electrode cells.

The wisdom of devoting two out of six articles to polarography might be questioned, but the articles themselves, on the hanging mercury drop electrode, by W. Kemula and Z. Kublik, and on organic polarography, by Petr Zuman, are excellent reviews by leading authorities on these subjects, both of which are finding increasing application. A more massive review, occupying a third of the volume, is that by Harry B. Mark, jun., Louis J. Papa and Charles N. Reilley on "Reaction Rate Methods". These have applications in the determination of mixtures of closely related compounds such as homologues, isomers and copolymers, which, so far, appear to have been rather neglected in Britain.

One chapter which seems out of place in this volume is that entitled "Mass Spectra of Organic Molecules" by Seymour Meyerson and John D. McCollum. In fact, this deals only with carbonyl compounds and allylic and related ethers, and the section on ethers, far from being a review, consists entirely of the authors' hitherto unpublished work. Moreover, the application of these results to analysis is referred to only in passing, while instrumentation is not even mentioned. The analytical chemist wishing to keep abreast of new developments, for whom this book is supposedly intended, would be sadly disappointed if he expected to find here a comprehensive review of the analytical applications of mass spectrometry. It is to be hoped that this subject will receive in a future volume a treatment more comparable with the high standard maintained by the other articles in this volume and its predecessor. R. J. MESLEY

CHEMICAL ICONOCLASM

Noble Gas Compounds

Edited by Herbert H. Hyman. Pp. xiii + 404. (Chicago and London: The University of Chicago Press, 1963.) 90*s*.

EVERY now and then we are forced into awareness of the areas of unnoticed ignorance in even the best cultivated fields of chemistry and physics. The noble gases of the atmosphere have figured twice in such dramatic happenings: in their original discovery and again, very recently, in the proof that they are not, after all, chemically inert. With the wisdom of hindsight, it now seems surprising that the chemical compounds of the 'inert' gases eluded detection for so long. Pauling and others predicted the existence of xenon fluoride thirty years ago, and all the thermochemical data are on record to extrapolate from the energies of the Te–F and I–F bonds to the conclusion that XeF_4 ought to have a favourable heat of formation. If Yost had worked in nickel or copper apparatus, instead of in quartz, he would certainly have isolated XeF_4 before the Second World War. In retrospect, the reactor chemistry group at Oak Ridge must actually have had xenon fluorides in their hands, but failed to draw the right (but seemingly far-fetched) conclusions from their poor mass balance for fission-product xenon in systems from which free fluorine was being liberated. It still remained for Dr. N. Bartlett, at the University of British Columbia, to do the crucial experiment: having proved that PtF_6 would oxidize molecular oxygen to $[O_2^+]\,[PtF_6^-]$, to infer that xenon, with its similar ionization potential, should behave similarly. The experiment was done and the right inference drawn, even though it now seems he was wrong in identifying the product as $Xe^+\,[PtF_6^-]$.

What happened then exemplifies the difference between the scientific worlds of 1890 and 1960. From

Rayleigh's first observation of the discrepancy in the density of 'atmospheric' nitrogen to the isolation of xenon, about seven years elapsed. During that time, according to the gentlemanly custom, the field was left to Ramsay, who had to work out the techniques, now taken for granted, for manipulating and separating small quantities of volatile substances. If Ramsay enjoyed exclusive prospecting rights in virgin territory, Bartlett started a gold rush. His first published note on so-called '$XePtF_6$' appeared in June 1962. By April 1963 the Argonne National Laboratory could organize a symposium with 58 papers from 105 authors, and the chemistry of xenon had already been pretty fully explored. The contributed papers covered the preparation and properties of the fluorides from XeF_2 to (probably) XeF_8; the oxides and oxy-acids; their thermochemistry; their solution chemistry; their structures as found by X-ray, electron and neutron diffraction; Raman, infra-red and ultra-violet spectra; electron spin and nuclear magnetic resonance; Mössbauer effect; extensive theoretical treatment and toxicology.

Noble Gas Compounds contains the papers presented at that symposium. After some papers on the historical background, nine laboratories contribute to the wide range of preparative experiments that opened up the field, including experiments of microcurie scale on radon fluorides and the isolation of krypton compounds by matrix isolation methods. The stability and reactivity of inert gas compounds are then put on a firm basis of thermochemistry before passing to hydrolytic reactions, the formation of the oxides and the perxenate salts. The way is next paved for theoretical treatment of the interesting valence problems—which are treated by several groups of theoreticians in the final few papers of the book—by establishing the stereochemistry, molecular dimensions and bond properties in great detail, using all the available diffraction and spectroscopic techniques. Rarely can so much have been done to clear up a new field of knowledge at one stroke.

This is not a tidily edited review; it is a set of research papers setting out new discoveries. As usual, one can question whether such symposium papers justify publication as a separate volume and whether the same material will appear repetitiously in the usual journals. In this case, the intense competition for priority certainly led to duplication of effort and identical experiments by different groups of workers. Thus consecutive papers present the crystal structure of XeF_4 as investigated (with identical results) at Brookhaven and at Berkeley. However, the sense of excitement and of a massive attack on an important problem are well conveyed. The papers are mostly terse and businesslike, logically arranged by the editor, and combine to give a view of the whole state of knowledge at that time.

The book prompts thoughts on the power of co-operative research and the advantages enjoyed by laboratories with a great range of skills and interests. More than half the papers come from U.S. Atomic Energy Commission institutions—18 from the Argonne National Laboratory alone. Four papers are from industrial research laboratories, reflecting facilities and a philosophy of research in industry that is almost unthinkable in Britain. Only four papers originated outside North America: from Yugoslavia, from Birmingham and one—sadly demonstrating the impotence of ideas not backed with modern technical resources—from Germany, once the homeland of fluorine chemistry.

All inorganic chemists will be interested in the subject-matter of the symposium; whether all will want to read the original publications rather than critical digests is another matter. On the other hand, the book may stimulate some thinking about the teaching of chemistry. In some subjects the 'case history' method has been found an effective study tool. A student who went intelligently through this collection of papers would emerge knowing a lot about the content and methods of modern inorganic chemistry, by seeing a whole range of ideas—preparative chemistry, theory and experiment in the elucidation of structure, thermochemistry and thermodynamic considerations, the comparative chemistry of the elements—all brought to bear on a single theme. The book should find a wide range of readers, but most will probably consider it rather expensive to put on their own bookshelves.

J. S. ANDERSON

WHAT IS TOPOLOGY ABOUT?

Introduction to Topology

By Prof. Bert Mendelson. Pp. ix+217. (London and Glasgow: Blackie and Son, Ltd., 1963.) 35*s*. net.

THIS book is outstanding. It is a modest introduction to a difficult subject, but the author has cast a spell of magic about the world of topology. He has written so clearly about the basic ideas of the subject, has been so honest in trying to bring it down to the early undergraduate level, that suddenly much of the difficulty and haziness often encountered by students of topology has faded away. At last, university teachers of mathematics have a suitable text for an early course in the subject.

The British edition of *Introduction to Topology* contains a preface by Dr. E. C. Zeeman, which is important because it puts the subject into proper perspective, both relative to school mathematics and in relation to other parts of university mathematics. Dr. Zeeman, who has recently been appointed to the chair of mathematics at the new University of Warwick (*Nature*, 200, 734; 1963), points out that the place of topology has changed a great deal, in that, at least in most British universities, while the subject was little taught a decade ago, it is to-day introduced in most universities in the first year. This is a radical change and a recognition of the fact that topological ideas pervade so much of modern mathematics. Topology is virtually defined as the study of continuity, and it is pointed out that the subject underlies every domain in mathematics and science which uses continuity.

What is contained in this remarkable book? The first chapter deals with sets and functions, including composition of functions and inverse functions. The second chapter deals with metric spaces and covers topics such as continuity, neighbourhoods, open and closed sets, and the equivalence of metric spaces. The third chapter is given to topological spaces. Such a space can be obtained from a metric space by discarding the distance function and retaining the open sets, although there are other ways of introducing a topological space.

Chapter 4 is concerned with connectedness, a term which, although a formal definition is given, may be described as follows: a subspace of a topological space is connected if it is impossible to decompose the subspace into two disjoint non-empty open sets. For example, on the real line single points and intervals are connected subsets, but the set of non-zero numbers and the set of rational numbers are not connected sets. There are various types of connectedness and, apart from the above, arcwise connectedness and simple connectedness are discussed. The former is stronger than connectedness in view of the theorem that an arcwise connected topological space is connected, but the converse is not true. The falseness of the converse is proved by a counter-example constructed with reference to the subspace of the plane consisting of the points (x, y) such that either $x = 0, -1 \leqslant y \leqslant 1$ or $0 < x \leqslant 1, y = \cos(\pi/x)$. Some interesting and important applications of connectedness are given, including the intermediate-value theorem, and various fixed-point theorems (including that of Brouwer).

Chapter 5, the final one, deals with compactness. At first compactness is studied in general topological spaces but later the restriction to a metric space is considered. A metric space is compact if every infinite subset A has at least one point of accumulation, P, the latter being defined as a point such that every neighbourhood of P contains infinitely many distinct points of A. The chapter closes with a section on identification topologies and spaces, including a discussion of the classical surfaces such as the torus, the Möbius strip, the Klein bottle and the projective plane.

All students of topology will find the reading of this book rewarding, and there is little doubt that the text will become a standard introduction to the subject.

L. S. GODDARD

ANALYSIS OF MICROCLIMATE

Physics of Plant Environment

Edited by W. R. Van Wijk. Pp. xvi+383. (Amsterdam: North-Holland Publishing Company, 1963.) 80*s*.

LAND plants are anchored by their roots in a porous medium providing water, nutrients and oxygen, and they grow when leaves use solar energy to reduce carbon dioxide to carbohydrate. Below ground, the physical environment of plant roots governs the conduction of heat, the flow of water, and the diffusion of water vapour, oxygen, carbon dioxide and ions. Above ground, leaves and stems are exposed to radiation and behave as sources and sinks of turbulent fluxes of momentum, heat, water vapour, carbon dioxide, pollutants, spores and small insects. The physics of plant environment is a diverse and youthful science. Although in British universities it is not yet recognized as a child of natural philosophy, it has reached the curriculum of several departments of agriculture. In Holland, Prof. van Wijk has for many years directed the Laboratory of Physics and Meteorology in the Agricultural University of Wageningen, and the book which he has edited and partly written is a summary of research, mainly in his own department, prefaced by three introductory chapters. There is little reference to work later than 1959.

The first chapter of *Physics of Plant Environment* is a statement of philosophy that will be shared by most agricultural physicists, In many farming problems, a simple physical model isolating a few relevant parameters will often give a better working solution than a purely empirical relationship derived statistically. The second and third chapters review the physical properties of the atmosphere and soil; and the theory, measurement, and estimation of solar and terrestrial radiation. In Chapters 4–6, van Wijk, de Vries and Derksen discuss the mathematical physics of soil temperature in the most comprehensive account of this topic that has appeared in book form. This section might more logically have followed Chapter 7, in which de Vries shows how the thermal properties of soil can be predicted from its composition, and summarizes measurements in several useful tables. Chapter 8 is on the turbulent exchange of heat in air with special reference to the theory of sinusoidal temperature variations, and Chapter 9 is a detailed account of the heat balance of glass-houses, in which J. A. Businger shows theoretically that the 'glass-house effect' depends on shielding from wind rather than on preventing radiative losses. Horticultural engineers will find this section a valuable source of reference. The final chapter, by F. H. Schmidt, presents equations for the diffusion of atmospheric pollution and quotes an interesting investigation where damage to vegetation around a steel works was greatest almost 1·5 miles from the source of the pollution.

The book has two weaknesses. First, although the scope of the book was never intended to match its comprehensive title, the index suggests that the editor has been too selective. There are 49 entries under 'temperature' and 'heat', 24 under 'soil', 13 under 'radiation', 4 each under 'evaporation' and 'photosynthesis', and 3 each under 'humidity' and 'carbon dioxide'. Other readers will regret this bias. During the growing season, soil temperature is one of the least important components of plant environment, whereas evaporation and photosynthesis are the main links between weather and plant growth and development. Evaporation is dismissed in a few pages and photosynthesis in a few lines.

A quotation from p. 266 illustrates a second weakness. "A systematic discussion of the application of the principles (of turbulent transfer) set forth in the preceding text to plant environment would largely surpass the scope of this book." (Yet a derivation of the dry adiabatic lapse rate gets space in Chapter 2 and this has little relevance to the central theme.) The writers have tried to describe the environment of plants without reference to plants themselves or to the ways in which they modify their own microclimate. Several chapters open with the development of complex mathematical theory and close with much briefer reference to experimental results. Neglect of plant-environment feed-back is almost inevitable in this attempt to treat environmental physics as an inductive science.

The authors, all Dutch, achieve remarkable fluency in English and there are very few minor flaws in a book that is distinguished for its clean and elegant lay-out. Symbols are qualified by a plethora of suffixes—many unnecessary. A diagram on page 97 shows an inconsistent heat balance. It is debatable whether the surface temperature of a lake can be measured without difficulty (p. 273); or whether the mathematical theory of buoyancy has not reached the stage of application to plant environment (p. 253).

Despite limitations of content and approach, the book will find its way to many shelves alongside "Geiger" and "Sutton", as a standard text on the physics and mathematics of soil temperature. J. L. MONTEITH

JURASSIC FLORA OF YORKSHIRE

The Yorkshire Jurassic Flora

By Prof. T. H. Harris. II: Caytoniales, Cycadales and Pteridosperms. Pp. viii+191+7 plates. (London: British Museum (Natural History), 1964.) 130*s*. net.

IN Volume 1 of *The Yorkshire Jurassic Flora* (1961), Prof. Harris has described the Thallophyta, Bryophyta and Pteridophyta. In Volume 2, he deals with seed-bearing plants, the Caytoniales, Cycadales and Pteridosperms. It has been found necessary to extend the series to four volumes. There are few areas of comparable size to Yorkshire which have yielded such considerable collections of well-preserved fossil plants from one geological formation. It is fortunate, too, that most of the plant fragments, leaves, etc., have well-preserved cuticles which may be isolated and used for purposes of identification. This method of investigation has been very effectively used by Prof. Harris in classification and in establishing the connexion between different organs of one plant species. A great deal of the best material on which the work is based was collected by the late Dr. Hamshaw Thomas and Prof. Harris himself.

The Caytoniales are a particularly interesting group, which has received much attention from morphologists. Thomas considered that the group exhibits features indicating possible relationship to the Angiosperms but perhaps it is more generally regarded as being closely related to pteridosperms. Prof. Harris has been able to distinguish four species in the genus *Caytonia*. The fossil remains consist of detached leaves (*Sagenopteris*), microsporophylls (*Caytonanthus*) and the ovuliferous parts

(*Caytonia*). The greater part of the volume is devoted to the Cycadales and pteridosperms, mainly represented by their leaves, but a few have related fructifications. The principal genera are *Nilssonia* (9 spp.), *Deltolepis* (3), *Paracycas* (1), *Pseudoctenis* (7), *Ctenozamites* (4), *Ctenis* (6), *Pachypteris* (2) and *Stenopteris* (3). Prof. Harris points out that a separation of these into two groups belonging to the Cycadales and pteridosperms respectively is difficult. The principal differences lie in the morphology of the leaf. The reproductive organs of a few are known and some species of *Nilssonia* and *Pseudoctenis* are cyads, while *Lepidopteris*, *Dicroidium*, *Xylopteris*, *Ptilozamites* and *Pachypteris*, which have known reproductive organs, are pteridosperms. He also suggests that *Ctenis* and *Paracycas* may be regarded as cycads, with *Ctenozamites* and *Stenopteris* as pteridosperms. There follow descriptions of cycad-like reproductive organs *Androstrobus* (3 spp.), *Beania* (2) and *Pteroma* (1).

There are three new genera and about twelve new species among those described. The sixty-seven text figures and the plates provide excellent illustration and will be welcomed by those who have not had the opportunity of examining actual specimens of the Yorkshire material. It is intended that Volumes 2 and 3 will be devoted to the Bennettitales, Ginkgoales and conifers.

J. WALTON

LEGISLATION ON DRUG ADDICTION

Narcotic Addiction in Britain and America

The Impact of Public Policy. By Edwin M. Schur. Pp. 281. (London: Tavistock Publications, 1963.) 35*s*.

NARCOTIC Addiction in Britain and America is primarily a reasoned criticism of the approach to narcotic addiction adopted by the Government of the United States since 1914. The first part provides a general introduction to narcotic addiction and summarizes the development of American policy. The second describes the British approach to narcotic addiction and includes a chapter on the characteristics and behaviour of narcotic addicts. The third part is devoted to possible reforms of American policy and the sources of objections to them. A summary of data describing a number of British addicts is contained in appendixes. The first summarizes the replies of thirteen British doctors specializing in the treatment of addiction to questions relating to addicts and addiction; the second summarizes personal data on thirteen narcotic addicts selected as 'representative' by these specialists; the third is a summary of a survey of attitudes to, and knowledge of, addiction in 147 randomly chosen residents in a London borough whose average age was just under 21 years.

The book provides a lucid account of the development of American legislation on narcotics since the Harrison Act (1914), which was the first of a series of repressive measures which have isolated the American addict from the medical profession and classed him as a criminal. As a consequence, in the United States, it is a crime to have unauthorized possession of narcotics or to be an addict. Thus, addiction is seen primarily as a legal problem. In contrast, the British approach is based on the belief that addiction is a medical problem. American doctors may have to stand trial for prescribing narcotics for an addict, a consequence which deters most of them from treating addicts in general practice. In Britain, narcotics may be prescribed under the National Health Service.

Schur examines the effects of the punitive policy practised in the United States and concludes that the lucrative black market in narcotics and the criminal behaviour of some addicts may simply be attributed to repressive legislation. This conclusion is based on a comparison of the 'typical' addict in the United States with a much fuller account of British addicts. Criminal behaviour is rare among British addicts, who can legally obtain cheap supplies of narcotics from their general practitioners. In the United States, however, addicts tend to become attached to criminal sub-cultures, both in order to obtain supplies of drugs and to obtain the money with which to pay exorbitant prices on the black market. Schur effectively explodes the myth of the 'criminal dope fiend' and finds that addiction in Britain is not associated with crime. Furthermore, he emphasizes the fact that the punitive measures adopted to control addiction in the United States do not, in fact, affect the importer and wholesaler as much as the addict himself.

In the last part of the book, legislative changes are discussed which would bring American policy more in line with British practice. A number of objections to liberal reform are disposed of, including the fear that addiction might increase (evidence indicates that, in Britain, narcotic addiction has decreased between 1935 and 1959), while some of the psychological factors which may sustain punitive legislation are critically examined. Relatively detailed recommendations are put forward concerning the short- and long-term care of the addict, which broadly reflect those of the Joint Committee of the American Bar Association and the American Medical Association. One very useful section deals with the way in which the differences between British and American policies have been minimized by authorities in both countries. This has had the effect of perpetuating the most unfortunate legal status of the American addict.

Narcotic addiction is considered a major problem in the United States and estimates of the number of addicts range from 45,000 to 1 million. In contrast, the number of narcotic addicts in Britain is probably between 450 and 700. These two countries also differ with respect to the distribution of known addicts according to age, sex and socio-economic status. The 'typical' American addict is young, male, and a member of an under-privileged minority group. In Britain, a high proportion of known addicts are doctors, dentists and nurses, and there is no preponderance of males. Thus addiction in Britain and the United States differs with respect to both incidence and distribution. Schur describes these differences but does not deal satisfactorily with either of them, though it is fair to add that they could be considered outside the scope of his main theme. However, his main arguments depend on the comparability of British and American addiction, in order that he may predict the consequences of reforming American legislative policy, and it is unlikely that American opponents of such reform will be persuaded until they are given a satisfactory account of the origin of the differences in the incidence of addiction in the two countries.

The main criticism of the book is that while addiction in Britain is described more or less thoroughly, a much less complete picture is provided of the addict in the United States. The description of the official policies adopted in these two countries is excellent, but the comparisons between the consequences of these policies would have been more compelling if comparable information had been supplied about these two addict populations. The British addiction statistics were all obtained indirectly from the Home Office, an all-night London chemist and, by questionnaire, from a number of specialists treating addiction. This information is supplemented by personal information obtained directly from five narcotic addicts. Some readers may consider the investigations of individual British addicts to be rather sketchy and regret that this opportunity to gather information about their problems, attitudes and behaviour was not fully exploited. In spite of this, Schur has provided a valuable summary of information about British narcotic addicts.

This book is written in a fluent documentary style and liberally supplied with quotations which should make it

of interest to both the specialist and the non-specialist reader. The book is generally free from typographical errors, but the practice of collecting footnotes at the end of the book is an irritating one which makes it tedious to locate the sources of the many quotations and references. There is an adequate index and a selected bibliography of 75 items.

UNIVERSITIES OF THE BRITISH COMMONWEALTH

Commonwealth Universities Yearbook 1964

A Directory to the Universities of the Commonwealth and the Handbook of their Association. Pp. xxxi + 1930. (London: The Association of Commonwealth Universities, 1964.) 105*s*.

The forty-first edition of the *Commonwealth Universities Yearbook*, the principal publication of the Association of Commonwealth Universities, follows, so far as its format is concerned, the traditions of its predecessors. This annual publication continues to be the most comprehensive directory as yet available of academic institutions of the British Commonwealth. It not only covers seventeen Commonwealth countries, including the United Kingdom, but also two countries no longer members but which have expressed a wish to remain in the *Yearbook* and to retain close association with the Association of Commonwealth Universities: those of the Republic of Ireland and the Republic of South Africa (Appendixes 1 and 2).

Commonwealth countries have been rapidly expanding their facilities for higher education. In Britain the Robbins Report on higher education recommended in October 1963 that there should be a further 28 institutions with full university status and that there should also be a substantial development of other sectors of higher education; and such plans can be paralleled in other Commonwealth countries. The *Yearbook* has become a yard-stick with which to measure these developments; for example, this edition shows an increase of 105 pages on the fortieth edition. Entries for the first time appear for the Chinese University of Hong Kong; the University of Burdwan, India; the University of Waikato, New Zealand; the University of Lagos Medical School, Nigeria; and the Universities of Essex; Kent at Canterbury, Lancaster and Warwick, in England. Some institutions now appear under a newly constituted form, and Appendix 4 contains a summary of information concerning the ten colleges of advanced technology in England and Wales, and certain Scottish institutions, which are to gain university status now that the Government has accepted the recommendations of the Robbins Report.

In the *Yearbook*, sections are devoted to each Commonwealth country. These in the main are prefaced by a "National Introduction", which is intended to supply a factual guide to the general background of university education in the country concerned. Then follow alphabetically the universities of that country. Members of staff are listed according to departments and details are given of administrative and other staff, associated or affiliated institutions, general information, and "The Year 1962"—the last-mentioned supplying details of developments, retirements, resignations, statistics, and degrees and diplomas awarded during 1962.

Besides the three appendixes already referred to, there are six others which consider: university admission requirements (Appendix 3); students from other countries in United Kingdom universities (Appendix 5); British academic institutions outside the Commonwealth (Appendix 6); a short bibliography (Appendix 7); the Commonwealth Scholarship and Fellowship Plan (Appendix 8); the Association of Commonwealth Universities (Appendix 9).

The *Yearbook* is rounded off by two invaluable indexes. The first, a general index, contains references to institutions, to subjects of study and to such topics as admission, degrees, superannuation, vacation courses, etc. The second is a name index which makes it possible to find at which university any of more than 50,000 men and women, who comprise the teaching and administrative staff of the universities of the British Commonwealth, are serving.

CITATION INDEXING

Science Citation Index

An International Interdisciplinary Index to the Literature of Science. Vol. 1: AABE–CAPL, 1961. Pp. xxx + 496. (Philadelphia: Institute for Scientific Information, 1963.) Five-volume set: 700 dollars.

A number of surveys have shown that the most generally used method of finding relevant papers is by looking at the references quoted in a known paper. This is a technique which is widely favoured by scientists, but it has the disadvantage that it can only go backwards in time. An attempt to overcome this point is the reason for the citation index, which is a directory of cited references each of which is accompanied by a list of citing source documents. Thus, knowing a relevant paper, it is possible to consult the citation index and find references to all the subsequent papers which have cited the known relevant paper. By working backwards and forwards in time it is claimed that a comprehensive collection of references on a given topic can quickly be obtained. Citation indexing has, for many years, been used in law; this series of volumes presents an attempt to apply the technique in the field of science. As such, it may be said to raise two points: first, whether citation indexing can usually be applied to scientific papers, and secondly, whether these volumes represent a good example.

Undoubtedly a citation index must suffer from certain built-in handicaps. Most of the references which an author cites are not directly relevant to the main theme of the paper and the result is that a high proportion of the papers to which one is referred will be of no interest. It is a weakness of this particular citation index that the searcher is given only the citing author and journal reference. It would have been possible to have included a list of the citing papers with their titles; no doubt this was omitted because of the additional costs incurred, but the result is that the user is compelled to refer either to other indexes or to the original papers to obtain any clue as to which reference might be of interest. While it is possible, if somewhat tedious, to compile a citation index clerically, it involves the type of sorting operation for which a computer is well suited. The resulting print-out is, however, in the usual computer print face, and the severe reduction in type size adds to the difficulties of its use.

Volume 1 of *Science Citation Index* covers 102,000 papers which appeared in the issues for 1961 of 613 source journals. It grew out of an earlier citation index in genetics, and there is a consequent emphasis on journals in the life sciences. It is claimed in the introduction that the journals have been selected for their inter-disciplinary interest, and that the number of journals covered will be increased in future years. As it is, for the physicist, this index covers only about 5 per cent of the 800 journals included in *Physics Abstracts* for 1961. While it would be unwise to underestimate the possible value of this method of indexing, I cannot visualize many situations where these volumes could be used more effectively than other existing indexes.
C. W. Cleverdon

The Complete Slimmer

By Prof. John Yudkin. Pp. 191. (London: MacGibbon and Kee, Ltd., 1964.) 30*s*.

IN his opening chapter Prof. Yudkin says that all of us are overweight who weigh more than we did when we were reasonably slim and trim in our twenties. But, having depressed at the outset most of his readers who are more than thirty years of age, Prof. Yudkin proceeds to give sympathetic consideration (and understanding) to our plight and provides a fairly simple way out of the dilemma.

His 'carbohydrate unit diet' is a method of reducing carbohydrate intake without directly altering the intake either of protein or fats. This is achieved by the allocation of so many carbohydrate units daily, the units being calculated from a table which is provided. Each carbohydrate unit is equivalent to 5 g of carbohydrate, and a test period of 15 units a day for two or three weeks is advocated to see what the effect is. If the weight reduction is regarded as being too fast or too slow the unit allocation can be adjusted accordingly. The table of carbohydrate units is illuminating. A raw apple represents 2 units (10 g), a glass of sweet wine 4 units (20 g) and one piece of 'Vitaweat' 1½ units (7½ g). An examination of this table brings an understanding of the increase in weight since the slim and trim twenties. One begins to recall glasses of sherry consumed over the years together with a decrease in the habit of running for buses. Innumerable lunches and dinners are remembered, while recollections of 20-mile country walks fade into the distance. At last the truth begins to dawn; in this affluent society we eat and drink too much and exercise too little.

Prof. Yudkin utters a warning against the numerous fads and miracle diets which appear annually, and he arms us with reason against the blandishments of the copywriters. For those who have a sufficiently strong desire to return to the slim and trim twenties, Prof. Yudkin undoubtedly provides a blueprint. Whether or not it is followed must remain an individual choice; but the efficacy and strength of his argument will be greatly helped by the purchase of a pair of bathroom scales.

P. D. NUTTALL

Le Développement du Vivant par Lui-Même

Par P. Wintrebert. Pp. 456. (Paris: Masson et Cie, 1963.) F. 44.

THIS second volume (the first was *Le Vivant, Créateur de Son Évolution*; see *Nature*, **198**, 117; 1963), which deals with embryogeny, concludes Mr. P. Wintrebert's thesis, the content of which is intended explicitly for the rehabilitation of the living being. Faced with two prevailing currents of contemporary biology the author writes strongly against: (1) genetics, which he considers to be a mechanism illusively rejuvenated by the transfer from the physical to the microphysical level of explanation; (2) causal embryology, a preformist idealism disguised under pseudo-scientific categories. "The two conceptions diminish the intervention of the living . . . in a very different way, either supernatural, by exalting its power, or natural, by degrading it" (p. 282).

The chemical lamarckism of Wintrebert is essentially 'vitalism': the protoplasm alone is alive, alone has the 'intelligence' and the ability to change itself by adaptation. It is also 'epigenetism': everything, at every moment of development, is actually present, and everything leads to a functioning result. There is no entelechy, no 'organizers', only protoplasm, paraplasm (some mitogenous activities of which have misled Speman and his successors) and genes. The absolute precision of the sequences is assured by the successive and orderly combinations, to the primitive protoplasm, of the genes which, during evolution, have accumulated 'adaptive hormones' elaborated by it. Evolution is therefore additive and irreversible: as opposed to Sewertzow and de Beer, Wintrebert considers that there can be no possible deviations other than, at the most, untimely interruptions due to lesions of the genes or to the circumstances of the environment (neoteny) and some lateral coenogenetic adaptations (like aneural motricity of the embryo). From the cellular to the pluricellular state and to the organic, the individual, as Haeckel would have it, moves, through a succession of first physiological and then phylogenetical mutations, the same way as its ancestors; but this recapitulation is essentially chemical, it generally saves the useless transitional forms. Therefore, it is, contrary to the theory of de Beer, phylogeny which constructs ontogeny and, contrary to the theory of Weissman, the soma which builds up the germen.

The book also includes two original chapters of first importance on the development of *Discoglossus* and the dog-fish: after sixty years of observation, Wintrebert is in opposition on quite a number of essential points (fertilization reactions, gastrulation, origin of the gonia) to the classical descriptions. An appendix offers some reflexions on intelligence, cancer and biological ethics.

Though the reader will not always agree with Wintrebert's ideas, he will enjoy the brilliancy of the remarks, the desire for clarity in the descriptions and discussions and, above all, the lesson in independence, which does not exclude fidelity to a tradition of thought: the diffusion of such activating substances within the body of a still embryonic science should not fail to help him to pass successfully through the unforeseeable course of its mutations.

J. LESSERTISSEUR

Treatise on Analytical Chemistry

Part 1: Theory and Practice, Vol. 4. Edited by I. M. Kolthoff and Philip J. Elving. Pp. xxv+1751–2705. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, Inc., 1963.) 189*s*.

THIS volume deals concisely and comprehensively with one of the most neglected fields of analytical chemistry. The book covers magnetic field and electrical methods of analysis. Each subject is divided up into several excellently written, clearly illustrated chapters. It is a complete definitive and authoritative source of information for all analytical chemists working in this rather specialized field.

Magnetic field methods are covered in four chapters, magnetic susceptibility (125 pp., 238 refs.), nuclear magnetic and electron paramagnetic resonance (69 pp., 140 refs), mass spectrometry (106 pp., 305 refs.) and ion-scattering methods (32 pp., 21 refs.). The section on mass spectrometry by Melpolder and Brown is worthy of special note as it critically, and yet lucidly, interprets the principles, practice and uses of this precise instrument, covering both organic and inorganic analytical applications. The comprehensive reference system makes this an excellent review article.

Electrical methods of analysis are sub-divided into eleven short chapters. These cover the scientific and instrumental fundamentals of this field. If any criticism can be levelled at the treatment of this subject, it might be that the large number of sub-sections causes a certain degree of overlap and a smaller number of larger chapters might have been better. Articles dealing clearly and comprehensively with electrochemical techniques (66 pp., 94 refs.), potentiometry (30 pp., 72 refs.), polarography (68 pp., 347 refs.) and coulometric analysis (49 pp., 258 refs.), to mention only a few, provide a wealth of information for the practical and theoretical worker alike.

In short, this edition more than justifies the fine reputation established by its predecessors, its only disadvantage being that it is rather expensive for individual purchase. It is, however, a must for all libraries associated with analytical laboratories.

J. THOMSON

SCIENCE AND HUMAN EVOLUTION

By DR. BERNARD G. CAMPBELL
5 Madingley Road, Cambridge

> "Discovery is an art, demonstration makes the Science."
> Charles Singer[1].

WHILE the scientific status of social anthropology has often been questioned, that of physical anthropology has not, and physical anthropologists would, in all probability, claim that their science, a branch of natural science, conforms to the methodology and traditions of science as a whole. Though the scientific method is perhaps more immediately effective in the experimental sciences it is just as powerful a tool in those sciences which depend not so much on experiment as on observation. Palæontology is a branch of the natural sciences which is not subject to experimental investigation (though it may utilize results of experimental biology), and it seems therefore worth enquiring how scientific method can most effectively be used by students of human evolution. It is scientific method which makes science, not experimentation, not discovery; it is scientific method to which we owe modern knowledge and technology, on which scientific progress depends; and it is scientific method which makes scientific knowledge distinct from religious and historical knowledge—which makes it demonstrable and universal.

How does this method operate in palæontology ? Most discoveries to-day are made as a result of a planned excavation, though this was not always the case. Important human fossils have been discovered by chance (Neandertal, Gibraltar, Cro-Magnon, Mauer); to-day, knowledge of human evolution and geology enable predictions to be made about likely sites for excavation (such a prediction was made many years ago by Dr. L. S. B. Leakey about the Olduvai deposits, and it has since been amply justified). A rather vague hypothesis of this kind—often little more than a hunch—is a necessary pre-requisite to palæontological investigation. After that, results depend not only on the skill of the investigator, but also on luck. (The well-organized and well-financed expedition to Java in 1906 under Mme Selenka returned without any further trace of Dubois's *Pithecanthropus*.) Deduction from a rather general hypothesis will give us a prediction which can act as a guide to palæontological investigation.

The fossils found can then be treated as the given facts or data of human evolution. On them are made observations—which are our attempts to describe them. On a series of these observations more exact hypotheses can be built by induction. These can then be tested by different means: by comparison with other well-founded hypotheses, and by further deduction and prediction. In this way we can move from rather vague general hypotheses to more precise ones. But at all times the power or truth of a hypothesis is its ability to predict, and nothing else. The predictions must be tested, and the result may be that the hypothesis will be corroborated, or it may need to be modified, or abandoned altogether.

In physics or chemistry, not only can experiments be devised to obtain data, but also observations can in some instances be made and interpreted without human interference—the subjective element is thus minimized. In biology this is less often possible, and in palæontology never. The science of palæontology is dependent on personal observations, and so by nature subject to subjective aberration. Even at the level of obtaining data, palæontologists face a number of difficulties: (1) data are limited and finite; (2) they are both difficult and expensive to obtain, and there is an element of luck in their discovery; (3) they are organic and therefore quite complex.

At the same time, in the observation of data, students of human evolution face special problems.

(1) In the first place, observations may be made at a number of different levels. Thus the form of the skull may be recorded in a descriptive manner with words such as dolichocephalic, platycephalic, tapeinocephalic, etc., or better still by measurement. Here the number of measurements and method of taking them are important. Beyond this, drawings, photographs, chemical analyses, spectrographical analyses, etc., may be made on the fossils. Quantitative data obtained in standard and recognized ways will be the least subjective and probably the most valuable. Owing to the limited amount of data at present available, however, it is essential that the maximum amount of observation be made on the fossil; every independent and descriptive measurement and every possible analysis must be carried out which is likely to prove of the smallest value. The quality of the observations will clearly affect the value of the hypothesis to be derived from them.

(2) A second difficulty which is closely related to this is that a number of different skills may be required in the observation of data. Basic anatomical knowledge is essential. Beyond this, genetic, taxonomic, mathematical, chemical, biochemical and physical skills may be required. In practice, the interpretation of fossil data, to be of greatest value to science, must be carried out, not by one man, but by a small team of workers with differing qualifications.

(3) A third difficulty is a special one for anthropologists. The relation of the material to its investigator is complex. Even in other fields of scientific research the investigator is subject to a host of prejudices. Wilfred Trotter[2] has written:

> "The dispassionate intellect, the open mind, the unprejudiced observer, exist in an exact sense only in a sort of intellectualist folk-lore ; states even approaching them cannot be reached without a moral and emotional effort most of us cannot and will not make."

How much more serious this problem is in anthropological research, when man investigates himself. Only a hundred years ago the theory of evolution caused a deep rift in man's mind. The idea of human evolution has still not been absorbed fully into our subconscious and a schism can be detected at many levels of thought and behaviour. The special relationship which we have with the material which we investigate affects our interpretation and observation of data in many ways. One of the most fascinating aspects of this problem is seen in the light of the investigator's world-view. At one extreme man sees himself as an animal which has achieved its humanity with struggle and which can be proud of its achievement. Such a man sees in his ancestry, not only a reminder of his own racial achievement, but also an explanation of his all too common failings in humanity. He may well prove to be tolerant and maintain his optimism in the face of human failure and cruelty which to another can only cause despair.

At the opposite extreme, an individual may see himself as fallen, or at least falling, far short of his potentialities and needs. He finds himself miserable, cruel and perhaps doomed, never to rise above the level of the super-intelligent animal which he is. Those who hold this view, though they may never realize it, may shun the idea of the animal in man and wish to confine his bestial ancestry to

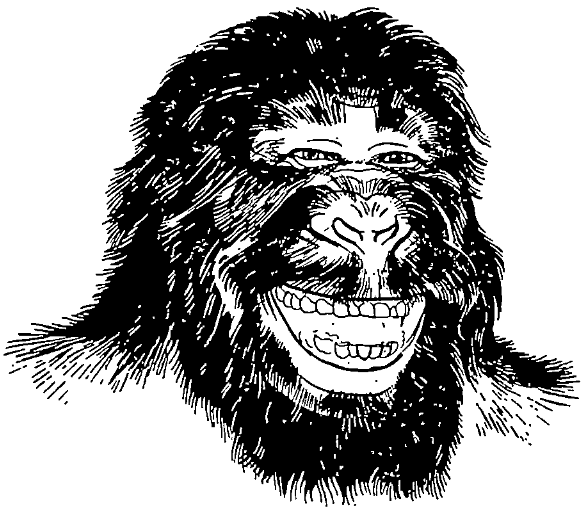

Fig. 1. *Zinjanthropus*, drawn by Maurice Wilson for Dr. K. P. Oakley

the most distant past. Such a man is all too conscious of the gulf between what is and what could be, of the best in man and of the worst. Man, he believes, can become a superman or a god, and his failure to progress is the cause of the deepest pessimism. Clearly these two views of the condition of man cannot fail to affect the frame of reference in which we study our origins (Figs. 1 and 2). Indeed, aberration resulting from the subjectivity of observation may be so serious as to render interpretation of fossil data of no value to science.

(4) A final difficulty which falls into this category is that discoveries in human palæontology receive world-wide publicity—the layman is intensely interested, and the investigator may find himself in the public eye. Publicity of this kind is not only ego-enhancing, but also compelling: the public will not only make a discoverer famous, but will also demand something in exchange. Once a discovery is signalled as great, the discoverer is obliged to maintain this image in his observation and interpretation of the material—the pressure again may be disastrous to that frail vessel which is the human mind. It has even happened that as a reaction to this pressure, a discoverer has completely rejected an early and quite valid interpretation for no good reason, and replaced it by a contrary form. This Dubois did, when towards the end of his life he revised his interpretation of the hominid *Pithecanthropus* find, and stated it to be a giant gibbon. The history of human palæontology presents us with many examples of how not only opinion, but money too, has caused the discoverer to behave in a manner antithetical to science. (A notorious instance was the discovery and disposal of the Le Moustier skeleton, by Otto Hauser. The skeleton was lifted from the Dordogne in 1908 without the recording of any archæological data and sold to the Museum für Völkerkunde of Berlin for 125,000 gold francs. It was destroyed in the Second World War.)

The observation of data is followed by its classification, and the erection of a hypothesis on the basis of such data, together with other data and hypotheses; this new hypothesis brings to discrete observations some coherent meaning. It is at this stage that science begins—scientific investigation itself is an art, and a very skilled one; the erection and demonstration of hypotheses are the beginning of science and it is in this way that scientific method brings its unique kind of universal knowledge. The erection of a hypothesis follows a number of distinct steps.

(1) All observations relative to the matter under investigation must be assembled from different sources, published and unpublished. Those most reliable can be treated as primary or self-sufficient evidence; other data may be set aside and tested at a later stage[3].

(2) One or more hypotheses can then be constructed which account for the maximum of reliable facts or evidence. It is, of course, by no means essential to devote time to the construction of hypotheses. Invaluable work has been done in anthropology of a purely descriptive nature, and in the absence of experiment, observation and description are the essential ground-work of palæontology. Charles Darwin gathered data for five years before he first formulated his hypothesis of evolution, and it was another twenty-two years between the formulation of this 'working hypothesis' in 1837 and its publication in 1859.

(3) The simplest hypothesis should be selected in the first place as a working hypothesis. This is the principle of Occam's Razor. The principle is particularly pertinent to studies of human evolution. As a result of the nature of the data there is no difficulty in the construction of unlimited hypotheses to account for them. Testing of complex hypotheses, which may suggest false predictions, has wasted much scientific endeavour. The most important point is that the hypothesis should not be otiose—it should contain no statement which is unnecessary to account for the observations on which it is based. On the other hand, the simple hypothesis will probably enable one to make more predictions, and will therefore be easier to test.

Occam wrote that "plurality is never to be posited without need". This suggests that in studies of human evolution the simplest coherent scheme which accounts for the reliable facts should be tested before a more complex (here probably polyphyletic) hypothesis. Adherence to this principle would speed the solution of many problems and ensure the most efficient use of scientific effort.

(4) Test the working hypothesis by comparison with other hypotheses and by deduction and prediction against further observations of a reliable nature (new discoveries, etc.)[11]. Meanwhile, the probable or possible status of disputed fossils can be assessed. This testing process is one of the most vital stages in the method of science; but it is here that palæontology restricts the pace. Experiments in physics and chemistry can be specially devised to test hypotheses. All the palæontologist can do is to look for new facts, a lengthy process, or make further observations on known data. (It may be mentioned in passing that there is a very large amount of fossil material

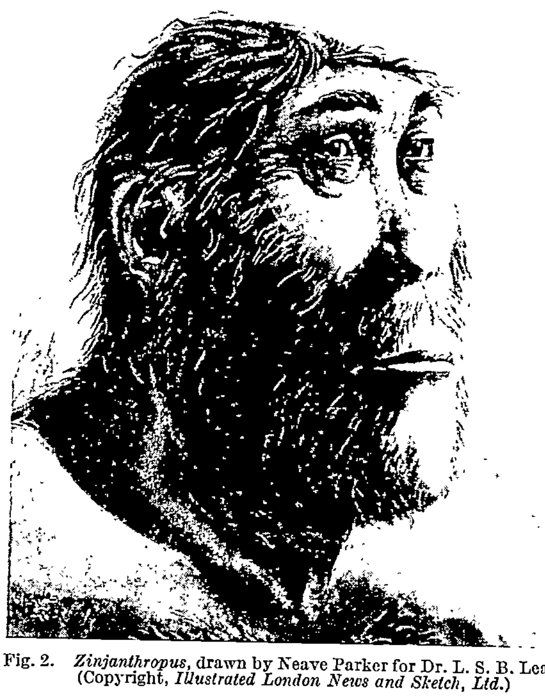

Fig. 2. *Zinjanthropus*, drawn by Neave Parker for Dr. L. S. B. Leakey. (Copyright, *Illustrated London News and Sketch, Ltd.*)

which has received very little attention and may prove of great value in the science of human evolution. Examples include the fossils from Steinheim, Jebel Kafzeh and Montmaurin.)

A logical corollary of the foregoing process involves the examination of any hypotheses or observations which do not support the hypothesis, together with an assessment of their validity. Such examination may result in a modification of the hypothesis, as may the addition of new observations.

(5) Assuming that the hypothesis is able to account for the majority of the most reliable observations, the scientist should then publish it with a demonstration of its validity. This is the second essential stage in the method of science. The purpose of this publication is: (*a*) to communicate what is believed to be an advance in knowledge; (*b*) to make the hypothesis available for further testing by other workers.

If there is one characteristic which distinguishes science, it is that it must be universal—it is the "search for judgements to which universal assent may be obtained"[1]. This characteristic necessitates such publication. If judgements are to be universally accepted, their validity must be effectively demonstrated. As a rule, therefore, scientists refrain from publication of working hypotheses until such demonstration can be given. The publication of a hypothesis with insufficient evidence does, however, carry heuristic value, though if accompanied by expressions of certainty, it may result in unnecessary controversy, because it is, in fact, open to doubt.

Publication is necessary at other stages, however, besides that of the demonstrable hypothesis. First of all facts must be published. In the case of fossils, this means that they must be placed in a public museum for the observation of any suitably qualified person who may wish to examine them. Fossil bones should not be treated as personal property; to withhold scientific knowledge is anti-science. Secondly, personal observations should be made available for the benefit of those who are unable to examine the original fossil data themselves, or who are not qualified to do so. The maximum number of observations should be made by standardized techniques and should be widely published. The withholding of observational data can never be justified (measurements, analyses, etc.).

These remarks may not only help us to analyse the work of others, but they may make our own contribution to the science more valuable. From them emerges one important conclusion: the science of human evolution is fraught with so many difficulties that it is of the greatest importance that a strict and rigorous methodology is followed. Failure to do so leads us from difficulties to confusion and misunderstanding.

Nomenclature and Hypothesis

Harrison and Weiner[3] have pointed out that the economy principle of Occam's Razor "should be extended to the activity of naming new fossil finds". By "naming" they mean, of course, the designation of fossils with Latin names, which Simpson[4] terms *nomina*, to create new species. The reason for this may not at first be clear, but if the meaning of the sexual species concept is fully accepted, it follows that the creation of a *nomen* involves the erection of a hypothesis.

The word 'species' is as old as the Latin tongue, but has changed its meaning with time. Until the eighteenth century, a species was a real and discrete unit—a kind of animal created as such by God and showing only the smallest variation. Although Linnæus accepted this concept he later recognized that considerable variability existed within species, though he did not doubt their original purity and constancy. Darwin observed minutely the geographical variation of species, and when he arrived at his hypothesis of evolution he saw that the term 'species' was to become a convenient label, no longer signifying a discrete population. The concept of the species had lost its meaning.

Our understanding has now changed once more. The sciences of genetics and ecology combined during the early years of this century to nourish a new approach to systematics which developed during the 1930's. To-day we recognize the species as a prime biological unit with objective criteria. The details of this important development are beyond the scope of this article and have been often described by Huxley[5], Mayr[6] and others. Suffice it to say that the use of a *nomen* as a 'label' for one or more fossils is no longer justified—as the concept of the species has developed, so the unit designated by the two Latin terms has come to assume a quite complex meaning.

The history of fossil discoveries contains very many instances in which fossils were named for purposes of convenience without an understanding of the modern species concept. Indeed, no scientist could be blamed greatly for this attitude before about 1935 because the modern species concept was until then in its infancy. The meaning of the term in fact did not worry palæoanthropologists because fossil finds were so few and far between. However, a large number of *nomina* accumulated and have since had to be critically assessed. The resulting confusion has not greatly helped the investigation of human evolution.

But the modern species concept is complex, and has certainly not been understood by all those who have more recently named Hominid fossil species. It would be fair to say that in the field of systematics or taxonomy the concept is now generally accepted and understood, thanks to the brilliant work of Huxley, Mayr, Simpson, Dobzhansky and others. Outside this field the situation is less satisfactory. This is very troublesome for palæoanthropology because fossil discoveries are usually made by either archæologists or geologists, and the fossils are usually described and published either by their finders or by anatomists. None of these skills is necessarily inclusive of taxonomic experience. The understanding of taxonomy usually reaches to a knowledge of the *Code of Zoological Nomenclature*, and of the hierarchical system of classification proposed by Linnæus, but the meanings to be associated with the different taxonomic levels are not understood. (In practice the ineffectual designation of *nomina* does still occur. Recent examples include *Homo sapiens shanidarensis* Senyurek, 1957; *Hemanthropus peii* von Koenigswald, 1957; *Homo homo* var *neanderthalensis* Blanc, 1961; *Sinanthropus lantianensis* Woo, 1964. The validity of all these is in doubt, and some of them are certainly *nomina nuda*.) The *nomina* are in fact still frequently treated as labels. I quote:

> "It always was and still is the custom to give generic and specific names to each new type without much concern for the kind of relationship to other types formerly known."
> Franz Weidenreich[12].

> "I think it will be more convenient to split the different varieties into different genera and species than to lump them."
> Robert Broom[13].

> "Since the names which we apply, *at any and every level in the taxonomic sequence* are inevitably arbitrary and artificial it does not, I believe, matter what we decide to do, provided only that the majority of those who are concerned in the classification, at any given time, are agreed as to how they will use the classification system. . . . All names and terms are after all, only 'arbitrary labels' which are made for the convenience of ourselves and our colleagues." Louis Leakey[14].

There is, of course, no objection to the use of names in any language as labels for either individual fossils or local populations (Simpson's N_1 and N_2 designations[7]) so long as they do not take the binomial Latin form. To avoid confusion such names should be explicitly stated to refer not to species, but to individuals or local populations.

Pergamon Press Publications

Neuropsychologia
An International Journal

Board of Editors: Prof.D.Denny-Brown, Boston City Hospital, U.S.A.; Prof.Dr.Cl.Faust, Neurologische Klinik, Freiburg-im-Breisgau, Germany; Dr.H.Hécaen, Hôpital St. Anne, Paris, France; Prof.A.R.Luria, Moscow, U.S.S.R.; Dr.K.H.Pribram, Stanford University School of Medicine, U.S.A.; Prof.H.L.Teuber, Psychology Section, Massachusetts Institute of Technology, Cambridge, U.S.A.; Prof.O.L.Zangwill, Psychological Laboratory, Cambridge, England.

This important quarterly journal is concerned with the psychological implications of injury or disease of the brain. Attention is focused mainly on the cerebral cortex, covering disorders of the higher mental functions and, in particular, those of perception, speech, and action. Contributions are not limited to purely clinical issues and the journal will be of interest to neurologists – both clinical and experimental – physiological psychologists, psychiatrists with a biological outlook, and neurophysiologists.

Subscription rates and an inspection copy will be sent on request.

Contributions are invited for editorial consideration. Full details for submission of manuscripts are given in the journal—write for an inspection copy.

Encyclopaedia of Materials Handling
in two volumes

Edited by **D.R.Woodley**, College of Production Technology, Ashford.

Chapter Headings:
Basic approach to materials handling problems; Conveyors and elevators; Cranes, hoists, lifting blocks and tackle; Industrial trucks; Ancillary functions and equipment; Utilization; Storage; Sheet and plate handling; Loading and unloading transport; Cargo handling; Various subjects; Reference section; Buyers' guide and index.
approx. 1400 pages £30 per set ($85.00)

Submicroscopic Ortho- and Patho-morphology of the Liver
in two volumes

H.David, Humboldt University, Berlin

Contents:
Technique, Parenchymal liver cells of the various animal species and of man; Sinusoid and star cells; Ortho- and patho-morphology of the various constituents of parenchymal liver cells; The perimportal field and changes of its components (fibrosis and cirrhosis of the liver, cholengiocellular carcinoma); The liver cell during proliferation; Mitotic processes in the liver; Effects of nutritional disturbances; Virus diseases; Intoxications; Necrosis and autolysis; Liver homogenate; Artifacts; Literature references; Subject index.
Volume 1 – 412 pages
Volume 2 – 361 photographic plates.
£25 per set ($70.00)

A Course of Higher Mathematics
Volumes 1 and 2

V.I.Smirnov, U.S.S.R. Academy of Sciences

Volume 1 – Elementary Calculus

Contents:
Functional relationships and the theory of limits; Differentiation; Theory and applications; Integration; Theory and applications; Series; Applications to approximate evaluations; Functions of several variables; Complex numbers; The foundations of higher algebra; Integration of various functions.
560 pages 90s ($12.00)

Volume 2 – Advanced Calculus

Contents:
Ordinary differential equations; Linear differential equations; Supplementary remarks on the theory of differential equations; Multiple and line integrals; Improper integrals that depend on a parameter; Vector analysis and field theory; Foundations of differential geometry; Fourier series; The partial differential equations of mathematical physics.
640 pages 90s ($12.50)

Analysis of Ancient Metals

E.R.Caley, Department of Chemistry, Ohio State University

Contents:
The heterogeneity of ancient metals and the sampling problem; Preliminary observations and measurements, qualitative tests, and choice of quantitative method; Gold and its alloys; Silver and its alloys; Copper and its alloys; Various nonferrous metals and their alloys; Iron and steel; The preparation of reports. International Series of Monographs on Analytical Chemistry, Volume 19
188 pages 70s. ($10.00)

The Planet Earth
second revised and enlarged edition

Edited by **D.R.Bates**, The Queen's University, Belfast

Contents:
The International Geophysical Year – S.Chapman; Origin, age and possible ultimate fate of the earth – G.P.Kuiper; The deep interior – K.E.Bullen; The crust – J.T.Wilson; The oceans – G.E.R.Deacon; Geomagnetic field – E.H.Vestine; Composition and structure of the atmosphere – D.R.Bates; Climate – E.T.Eady; The general circulation of the atmosphere and oceans – E.T.Eady; Ice ages – E.J.Opik; Meteorology – B.J.Mason; The ionosphere – J.A. Ratcliffe; The airglow – D.R.Bates; Aurorae and magnetic storms – V.C.A. Ferraro; Meteors – A.C.B.Lovell; Cosmic radiation – J.G.Wilson; The radiation belts – J.W.Dungey; Genesis of life – J.B.S.Haldane; Appendices; Indexes.
384 pages 42s

Mechanics of Automobiles

H.E.Barnacle, Senior Lecturer in Mechanical Engineering, College of Technology, Oxford

Intended mainly for students at Colleges of Technology studying for the examinations of H.N.C., H.N.D. and A.M.I.Mech.E., and with some chapters suitable for B.Sc. degree students, this book deals with the application of the basic theory of mechanics to problems arising from the motion of an automobile. Many problems and worked examples are included.

Contents:
Vehicle performance – linear and angular motion; Vehicle braking and brakes; Dry friction clutches; Gear boxes; Couplings between non-axial shafts; Balance of reciprocating engines; Cams and valve gear; Suspension, steering and tyres; Gyroscopic effects; Vibration.
260 pages. 35s net ($5.00)

Offered for sale by:

Robert Maxwell & Co Ltd

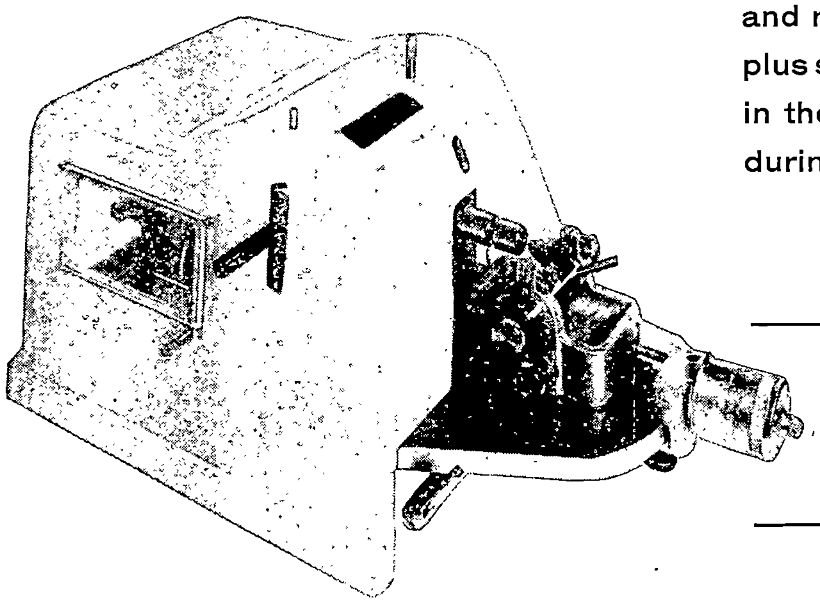
International, University and Industrial Booksellers
Waynflete Building, 1–8 St. Clements, Oxford. / 4 & 5 Fitzroy Square, London W.1. / 2 & 3 Teviot Place, Edinburgh 1. / 44–01 21st Street, Long Island City 1, N.Y. / 24 Rue des Ecoles, Paris Ve. / Kaiserstrasse 75, Frankfurt-Am-Main.

Pergamon Press books are distributed in the Western Hemisphere and the Philippines by The Macmillan Company, 60 Fifth Avenue, New York 11, N.Y.

Highly Successful

ULTRA-MICROTOME

The outstanding success of this microtome for electron microscopy has resulted in rapidly-increasing sales to discriminating users, in both the New and Old Worlds, and the instrument is right at the top of its class. This is due to its unsophisticated design, simplicity and reliability in operation, plus skill and workmanship in the Cambridge tradition during manufacture.



Some of the outstanding advantages:

- Strip hinge suspension—no friction or backlash
- Mechanical specimen advance—accurate calibration of section thickness
- Fine adjustment of automatic advance—steps of 5mμ from zero to 150mμ
- Full range of knife adjustments—tilt, traverse, rotation and micrometer advance
- Large specimen travel 0.1 mm by automatic advance
- Large specimen area—cuts 3 x 4 mm if needed

The Cambridge Ultra-Microtome is gravity-operated, and has no motor to cause vibration.

Send for List 344N. For future publications, ask for Mailing Form N/8/64

Cambridge **ULTRA-MICROTOME** (A. F. HUXLEY PATTERN)

CAMBRIDGE INSTRUMENT COMPANY LTD 13 GROSVENOR PLACE LONDON S.W.1

The understanding of how the species concept can be applied to fossil finds must follow two stages. The first is to be clear about the meaning of a biological species or biospecies; these species can only be recognized at a given moment in time and are defined as "groups of naturally or potentially interbreeding natural populations, which are reproductively isolated from other such groups"[6]. This concept of the biospecies is essential to the theory of evolution, since it is when two closely related groups of animals cease to interbreed that they become two species and henceforward can evolve in different directions to form eventually perhaps two entirely different families. But this concept of the biospecies can only be applied to a moment in time—it does not recognize the dimension of time.

A species in palæontology is an extension of this idea. It is a fundamentally different kind of unit and has been called a chronospecies or palæospecies. Such species can be recognized in two instances:

> "(1) in separate lineages (contemporaneous or not) between which significant interbreeding does not occur ; (2) at successive stages in one lineage but with intervening evolutionary change of such magnitude that populations differ about as much as do contemporaneous species."[4]

That is to say, that we must attempt to divide up each evolving lineage into temporal and morphological stages which show approximately the same amount of morphological variation in time as an average biospecies does in space. I have quoted Simpson[4] as a convenient reference; but this is not a new concept. It was already fully accepted by 1943 [7] and was in use years earlier.

From an understanding of the concept of the palæospecies follows the realization that the creation of a new palæontological species involves the erection of a hypothesis. This unwritten hypothesis could be stated somewhat as follows:

> The species *A-us b-us* (of which specimen Reg. No. 1302 in the Natural History Museum, Timbuctu, is the holotype) is believed to have existed as a group of naturally interbreeding populations over a certain area . . . and with a variability typical of modern living biospecies, and also to have been evolved from, and to have evolved into, other species which are separated by the amount of morphological difference which is usually associated with a species in space at the present time. The species represents a stage in an evolving lineage and will no doubt prove to be divisible (if not already so) into a number of sub-species in both the dimensions of space and time. Furthermore, the species can be distinguished from its neighbouring species (in space and time) by the following characteristics, etc.

The *Code of Zoological Nomenclature* states that for a name to be valid it must be "accompanied by a statement that purports to give characters differentiating the taxon" (Article 13 (*a*) (i)). It is scarcely necessary to state that this implies that the taxon must be differentiated from its nearest neighbours in evolution. Mayr (1942) states: "The diagnosis should include a direct comparison with the nearest relative"[6]. It would scarcely be of value to list the characters common to the family in which the fossil falls to distinguish it from a related family; on the contrary, the diagnosis must be pertinent to its function—that is, to enable other discoveries to be assigned to one or other of two species. The *Code of Zoological Nomenclature* is not in a position to state whether such a diagnosis is effective, just as criminal laws can do little more than punish a breach of the legal code. They cannot instil virtue, and similarly the *Code of Zoological Nomenclature* itself cannot ensure the presentation of an effective diagnosis; but the methodology of science can, for *it is in the diagnosis that we find the demonstration.* It is here that the hypothesis of the new species must stand or fall; it is here that science will train its critical eye to discover the validity of the hypothesis. The diagnosis must support the hypothesis for the species to stand, not in law, but in reality. It is precisely here that publications of new species so often fail. (Many examples of this state of affairs could be quoted. The most topical, and one of the most important, concerns the creation of the taxon *Homo habilis*[8]. In their original publication the authors stated that *Telanthropus capensis* "may well prove, on closer comparative investigation, to belong to *Homo habilis*"; thus the effective demonstration of a novel taxon was negated[9]. The name is valid, but the species has not been effectively shown to have existed, as a distinct taxon.)

I have here attempted to suggest how an understanding and strict use of scientific method may help us to avoid some of the problems which arise in palæoanthropology. Not only will this make our endeavours more fruitful, but also in an anthropological science a proper methodology will obviate much argument and ill-feeling which has, from time to time, been reported in the Press. Scientific communications must be clear, and so far as possible open to no misunderstanding. Since improvement in method, and better presentation of observation and hypothesis are open to palæoanthropologists, it would be the height of folly to neglect them.

I thank Prof. Philip Tobias and Mr. John Wilson for their advice.

A DARWINIAN APPROACH TO IMMUNITY

By Sir MacFARLANE BURNET, O.M., F.R.S.*

Walter and Eliza Hall Institute, University of Melbourne

THE production of antibody by the immunized animal has gradually developed over the past ten years to become one of the key problems of general biology. With the progressive clarification of the process of protein synthesis and particularly of enzyme synthesis, everything points to a progressive transfer and transcription of genetic information stored in DNA, through the now classic machinery of messenger-RNA, ribosome and transfer RNA to the specific sequence of amino-acids in the polypeptide chain. Although there is still controversy on the point, there is good evidence that the secondary and tertiary configuration which will be taken by a single polypeptide chain or a functional complex of more than one chain are determined essentially by the sequences of amino-acid residues, the siting of the cysteine residues capable of forming intra-molecular disulphide bridges being particularly important. The whole specific structure of an enzyme on this view is genetically determined. At first sight, then, the apparent ability of an animal to produce in response to any one of many thousand potential antigens a protein with a precise complementary pattern, allowing firm and specific union to the antigen used, is a major paradox. The so-called instructive theory initiated by Breinl and Haurowitz[1], refined by Pauling[2], and given its most recent expression by Karush[3], claimed that the differences between two antibodies were due, not to differences in amino-acid content or sequence, but resulted from the fact that the final configuration was taken up against the antigen as a template, the initially plastic configuration being fixed by the development of intramolecular S—S and hydrogen bonds. Evidence from several sources seems to render such a view untenable. Koshland and Engleberger[4] have shown differences in amino-acid constitution of two antibodies from the same rabbit; Buckley *et al.*[5] have shown that completely denatured γ-globulin fractions can regain immunological specificity on renaturation.

---

* Substance of a University of London Special Lecture in Pathology delivered on June 11.

If, on the other hand, antibody specificity is genetically determined, we are forced to assume either that all antibody-patterns are laid down in the fertilized ovum or that they arise by a process of random emergence which has the general character of somatic mutation and which is afterwards subject to continuing selection for survival within the lymphoid cell population of the body.

The present contribution is intended to support the view that somatic mutation is an adequate, and probably the only, source of immunological pattern and that the nature of the lymphoid system is such that clonal selection, positive and negative, can mould the population of mutants to provide the exquisitely adapted structure of immunological surveillance and defence.

Looked at broadly this gives us what can be called a Darwinian picture of micro-evolution among the lymphoid cell populations of the mammalian body. These cells, being highly expendable and constantly renewed, must necessarily be subject to a process of selection for survival in which clones play the part of species and sub-species in classical evolution.

Somatic Mutation in Mammalian Cells

Mutation is defined as a rare random and irreversible change in the genome of an organism or cell, with the necessary implication that any phenotypic manifestation of the change may potentially or actually be shown by all descendant organisms or cells. If we exclude provisionally changes which might arise in hypothetical ribonucleic acid (RNA) structures, mutation may arise from any form of change in the nucleotide sequence of DNA resulting either from point mutation as a single nucleotide or from some type of 'break and mend' lesion, deletion, inversion or even mitotic crossing-over, compatible with the continued functioning of the cell.

There seems no reason to doubt that mutation in somatic cells is of the same general quality as in germ cells and perhaps of equal or greater frequency. The studies on fleece mosaicism of sheep by Fraser and Short[6] provide a striking demonstration that a certain mutation may occur during the period of primary segmentation of the fertilized ovum and that its frequency throughout is proportional to the number of cells present. Mutation can in general be equated with error resulting from accident and it is reasonable to assume that accidental damage to DNA sequence is likely to occur when the segment concerned is active in transcription of information to RNA as well as in replication. Somatic mutation in relation to functional activities of a cell type may therefore be considerably more frequent than germinal mutation.

Even so the chance of mutation will always be small. If we adopt a frequency of 10^{-4} as the upper limit for any given cistron any modified protein produced as a result of mutation in a single cell will be undetectable in the presence of 10^4 times as many unchanged cells. Somatic mutation is only demonstrable when its effect can in one way or another be magnified.

With only some as yet undemonstrated exceptions in principle, mutation in a mammalian somatic cell is significant only if it gives rise to an observable clone of descendants. The conditions under which this may happen are: (1) The mutation occurs early in embryonic development in a cell from which a significantly large number of descendant cells arise. (2) The mutant cell has, as a result of the mutation, a selective proliferative advantage over its congeners and finds the conditions that may be needed for that proliferative advantage to be manifest.

From our present point of view the most important of these processes is the change which makes a mutant susceptible to the action of a specific mitotic stimulant present in the body. This is one way of interpreting the phenomena of conditioned malignancy, and the clonal selection theory of immunity is based on the assumption that a lymphoid cell by reacting immunologically with a corresponding antigenic determinant may thereby be stimulated to active proliferation. For 'normal' lymphoid cells, the antigenic stimulant is foreign or at least normally inaccessible, but in auto-immune disease the position approaches a conditioned malignancy even more closely, with a normal body constituent acting as the proliferative stimulus.

It should be emphasized that the nature of antibody is such that very small amounts can be demonstrated and titrated in the presence of a great excess of globulin lacking the specific reactivity for which we are testing. If new antibody patterns arise by mutation then it may be possible to detect the activity of a very small clone of descendant mutants or even in specially suitable circumstances a single active cell.

Physiological Phases of the Lymphoid Cell

There is now almost conclusive evidence that three functionally distinct types of cell, all with immunological potentialities, can be derived from stem cells of the type commonly present in the thymic cortex or in the substance of a germinal centre elsewhere in lymphoid tissue, and usually called large lymphocytes or blasts. These cell types are: (1) the small lymphocyte; on appropriate stimulation many, perhaps all, lymphocytes can become proliferating stem cells and the lymphocyte can best be regarded as a 'memory' cell from which the two actively functional forms can be derived; (2) cells of the plasma cell series, the active producers of antibody; (3) mast cells which can be regarded as concerned with pharmacological concomitants of immunological activity.

If it is legitimate to treat the stem cell and its derivatives as phases of the immunologically competent cell, all must be assumed to possess the same (somatic) genetic potentialities of immune reactivity. This can be most simply, if perhaps inadequately, expressed by saying that all carry receptors of the same specificity as that of the antibody produced by plasma cells of the family.

Current Picture of γ-Globulin Structure

Antibodies as present in plasma or serum of an immunized animal are heterogeneous, both physically and functionally, and, for chemical examination, it has been expedient to concentrate on the most 'typical' antibodies such as those found after prolonged immunization with a well-defined antigen. In rabbits, such antibodies are definable as γ-globulin of sedimentation rate 6·6–7S and mol. wt. 160,000, and it is these $7S\gamma 2$- or γG-globulins which have been most examined.

The specific relationship of antibody to the corresponding antigen is implemented by a complementary steric relationship of molecular pattern on relatively small areas of antigen (the antigenic determinant (A.D.)) and antibody (the active patch (A.P.)). Antigenic determinants may be of widely varied chemical nature but the active patch must, in every instance, be composed of portions of one or more peptide chains.

Examination of the proximate components of γ-globulin has resulted in a wide acceptance of Porter's diagram[7] as an appropriate model. In this the $7S\gamma$-globulin molecule is composed of pairs of $A(H)$ and $B(L)$ peptide chains linked by S—S bonds. The A and B chains appear to be governed by distinct genetic determinants and there is some tendency to regard the portion of the A chain which forms Porter's piece III as being distinct (? genetically) from the rest. There is some controversy about the relation of the active patches to the Porter model, but present American opinion (cf. Gally and Edelman[8]) seems to be firmly in favour of the APs being the joint responsibility of parts of both A and B chains. The two active patches appear to be located at each end of a flexible elongate molecule approximately 250 Å × 40 Å, they are of similar specificity[8] and may be thought of as small depressions in the general surface of the protein into which complementary ADs can fit.

No accurate statement can be made about the number of amino-acid residues directly concerned in the active patch. It is probable, in fact, that the number is in a sense indeterminate, but a rough estimate of 10–20 per patch[6] may represent the correct order of magnitude. On such an estimate the 2 active patches would directly involve only about 2 per cent of the 1,500 ± residues in the globulin molecule. Any change in the species or sequence of this 2 per cent would have a correspondingly great effect on specificity of the antibody. In addition it would always be possible that amino-acid changes in other parts of the polypeptide chains would have modifying allosteric effects on the active patches, for example, in increasing or decreasing avidity for a given antigenic determinant without change in specificity as such.

Random Character of Immunological Pattern

In order to account for the facts of immunological tolerance both natural and experimentally induced, both Jerne[9] and myself[10] have held that some process of randomization of specific pattern was necessary. Self-recognition is not susceptible to discussion in terms of instructive theories and, in any type of selection theory, demands the production of a large number of random patterns from which patterns reacting with accessible body constituents can be eliminated by contact with the antigenic determinants at an appropriate stage of physiological maturity.

It is unquestionable that the common features of all $7S\gamma2$-globulin molecules must be genetically determined. These include the general character and relationship of the A and B chains and their main antigenic determinants. The same requirement will hold equally for the other types of immunoglobulin. It is against this background of genetically determined structure that the somatic mutational origin of diversity of pattern must be considered, and it is axiomatic that any type of genetic change which destroys the character of the product as a γ2-globulin is irrelevant to the problem.

Smithies[11] has recently provided a suggestion as to how such a random production of patterns could arise. Small inversions of the portion of the genome coding for significant sequences of the A and B chains could obviously cause major changes in specificity. In more general terms we can accept that any change in the relevant area(s) of the genome whether by point mutation or by any form of deletion, inversion or mitotic cross-over of 'break and mend' type can produce changes in amino-acid sequence and, depending on whether they involve the active patch areas or other regions, will change specificity or modify it. The only limitation which holds similarly for all somatic mutations that can be examined is that the change should not destroy cell viability or so change the protein concerned that it is unrecognizable as γ-globulin.

The essence of this extension of Smithies's hypothesis is that the highly specific pattern of the active patch based on relatively few amino-acid sequences is subject to major change by minor genetic reorganization in the appropriate segment, while change elsewhere may be 50 times as frequent but will produce only such changes as modify the avidity or range of action of the antibody concerned.

Jerne's 'Antibody-plaque' Technique

One of the most striking recent developments bearing on clonal selection theory has resulted from the work of Jerne *et al.*[12] using a technique by which antibody-producing cells can be directly enumerated. This is for the present limited to antibody capable of producing, with complement, hæmolysis of red cells; in Jerne's system mouse spleen provides the antibody-producing cells which are tested against sheep and rabbit cells. The essential features are: (1) in normal 8-weeks-old mice there are small populations, ± 100 cells per spleen, which can produce hæmolysis of sheep or rabbit cells; (2) the two populations concerned are distinct and independent; (3) immunization with sheep red cells provokes a rapid rise in the number of cells effective against sheep erythrocytes but no change in those lysing rabbit cells and vice versa.

These results have already been confirmed in many laboratories and the only simple interpretation is the spontaneous occurrence almost certainly by somatic mutation of small numbers of cells with the pattern needed for each particular type of immune reactivity.

Additional Evidence in Favour of the 'Darwinian' Approach

The concept that all immunological phenomena represent the selection of qualities that have arisen by random process allows a wide range of phenomena, which have tended to be passed over as meaningless, to fall into place. Every laboratory immunologist is aware of the wide variability in the response to a single antigen in any group of animals of the same species. Dixon *et al.*[13], in a classic paper on the immunological production of nephritis, gave a large number of rabbits prolonged daily injections of relatively large amounts of bovine serum albumin. The effect on the kidney depended wholly on the differences in response. Those rabbits producing very small amounts of antibody were the only ones to suffer serious nephritis. Three other substantial groups, comprising high titre antibody producers, medium antibody producers and those which produced no antibody, had transient or no lesions. Whenever we have immunized a group of genetically uniform inbred mice, there has been a wide scatter in antibody titres. As part of the same pattern, we have the difference between poor antigens in which only a small proportion of animals give any antibody at all (yet, with large enough numbers of animals, an occasional 'good' serum can usually be obtained) and the good antigens, like bacterial flagella or $T2$ bacteriophage, where nearly all animals respond well.

Throughout the immunological literature, there are accounts of the extreme heterogeneity of antibodies at both physical and functional levels. Fahey[14] has reviewed the subject extensively and, more recently, Edelman's indirect evidence[15], and the direct findings of Koshland and Engleberger[4], indicate that there is also heterogeneity in amino-acid composition of physically similar antibodies. Evidence of a further type of heterogeneity among antibodies has recently come to light with the recognition both in rabbits[16] and in human beings[17] of antigenic differences between purified antibodies. This, presumably, points also to structural differences in amino-acid sequences. The highly relevant exception is the individuality and homogeneity of myeloma globulins and the retention of that character on transfer of a suitable mouse plasmacytoma to a new host[14]. The fact that, with very refined methods, sub-populations of myeloma globulin molecules can be observed in some is also to be expected from the hypothesis.

Both the irregularity of response and the extreme heterogeneity of antibodies are necessary consequences of a hypothesis of random development and selective proliferation. This is not the place to elaborate the many similarities which can be observed between the micro-evolutionary process by which the body develops its population of immunologically competent cells and antibodies and evolutionary processes in the standard sense, but, on these two points, the analogies with the evolutionary radiations that have occurred with each new step in evolution are obvious.

This theoretical approach is concerned only with: (1) the origin of immunological pattern; (2) its passage to descendant cells and further modification by mutation; (3) the process of selective proliferation under the stimulus of union with corresponding antigenic determinant. Several important and controversial problems are left untouched: (1) The possible transfer of genetic information determining immunological pattern from one cell to another. (2) The form in which an antigenic determinant is capable of stimulating effectively the receptors of a potentially reactive cell. (3) The number of antibodies which can be produced by a single cell. It seems likely that these questions are soluble in principle by experimental work in progress in many laboratories and that the uncertainties they represent do not invalidate the approach which has been adopted.

Summary

An extension of the clonal selection theory of immunity to its logical conclusion relates the origin of specific immunological pattern wholly to random changes in the segment of the lymphoid cell genome which codes for the *A* and *B* polypeptide chains of γ2-globulin and the equivalent constituents of the other immunoglobulins. It is suggested that no greater mutability may be required than in any other type of functioning somatic cell, provided it is accepted that specific union of antigenic determinant with cell bound antibody acting as receptor initiates proliferation of the cells concerned. This would provide the selective forces needed to mould the populations of the various mutants that can arise, to fulfil the body's immunological requirements.

PROS AND CONS OF INTERNATIONAL RESEARCH CENTRES

AT the meeting of the Society for Visiting Scientists on June 3, great interest was expressed in the potentialities of international research centres. It was admitted from the outset that there is no intrinsic merit in international research as such, since the important thing in any scientific work is the result, not how or where the work is carried out. The justification for any proposed international effort must therefore be carefully examined: the factors making for success will by no means always be the same, and the fact that one such centre may have succeeded is no adequate reason for assuming that others will. In fact, both scientific and political factors enter into the argument and either element would be neglected at one's peril.

The first essential was the clear demonstration of a genuine scientific need. In the case of the European Organization for Nuclear Research (Conseil Européen pour la Recherche Nucléaire) (CERN), the obvious example of a successful international research centre, the starting-point in the demonstration of the scientific need was the poor state in which European nuclear physics found itself after the Second World War. This, of course, was scarcely enough in itself: there was, in addition, the undoubted fact that the equipment requirements of nuclear physics research had by this time reached such a stage that they were quite beyond the financial resources of any Western European country. The CERN synchrotron, which had taken years to build, had, in fact, acted as a cement for the organization. The next stage in the development of the subject, a 300-GeV machine, which was already being discussed, would cost about £100 million, which would strain the resources of the existing Western European countries, and an organization was already being suggested which would include Europe, the United States, and the U.S.S.R. Any stage beyond this would presumably make it necessary to call in some of the other planets, which might raise difficulties.

In any such demonstration of the scientific need it was important to ensure that the scientists themselves were on one's side. Some of them might well feel that expenditure on international research might reduce their own national research budgets. Experience at CERN suggested that this was not the case but rather that the success of an international project might well catalyse increased national expenditure.

The proposal, now under discussion, for an international European institute for molecular biology presented a rather different picture of scientific need, though the sentiment behind the present drive for its formation was essentially similar to that which had led to the setting up of CERN. In this case the proposal might succeed, it was suggested, rather because it was so cheap than because it was so expensive. To begin with, molecular biology is a subject which needs a large group of different techniques and disciplines. Europe at present has nothing to equal the concentration of relevant techniques which the Boston (U.S.A.) area, to take one example, can offer. There is the Cambridge group, the work of Sir John Randall's Department in London, and the work of the Pasteur Institute in Paris. None of these covers more than about one-third of the field. However, unlike the CERN concept, the subject is only moderately expensive in plant and equipment but is very expensive in people. On top of this research situation is imposed the need for a centre where young men in Europe can train in this subject.

To establish such a centre only one or two men from each country would be needed for long-term appointments, so there would seem to be no serious risk of depleting the scarce man-power in each country to an undesirable extent. At present, in any event, no country was getting full value from the men it did have working since these were often too isolated. The cost of an International Institute in this field might be between 2 million and 3 million dollars per annum in contrast to CERN, for which the United Kingdom contribution alone was £2 million per annum. There was as yet no agreement about where such an Institute should be situated and whether, for example, it should be where the subject was already strong or where it was weak. One suggestion was that it might be situated near CERN, since it would be mutually profitable for the molecular biologists and the physicists to be able to talk to each other. A note of caution was sounded in a suggestion that the mere establishment of an institute would itself tend to fossilize the discipline into its present channels and to inhibit new interchanges with yet other disciplines. It was at least generally agreed that there was a strong argument for setting such an institute in an area which could provide a wide-ranging intellectual background.

A third example of an area in which international research was being urgently discussed was provided by cancer research. In this case there was at present thought to be no genuine scientific need for an international institute since there was no work to be done of a kind which could not be carried out in present national institutes. On the other hand, there were specific problems and projects which transcended national boundaries and to which effort could only be devoted by international co-operation. Obvious examples were geographical disparities in the incidence of different types of cancer and the investigation of specific cancer problems in areas in which the national effort was inadequate.

The experience of running CERN presented some interesting lessons. Given general acceptance of the need for an international organization desirable administrative simplicity could be achieved in running it. Each member country of CERN had two representatives on the governing body and voting was on a simple majority basis except for budgetary recommendations. This latter point arose because, on a numerical basis, the smaller members who carry only a very small proportion of the expenditure could out-vote the few large members who paid for most of the budget. Therefore, on budgetary matters, those in favour had to represent more than 50 per cent of the expenditure. Other administrative principles were also simple and desirable: for the ordering of equipment, lowest tenders were accepted and there was no national quota (which meant that the United Kingdom received few of the orders); no patents were taken out, since there was general agreement that this was a cultural activity from which all would benefit; and jobs went to the best men, with no national considerations. The individual workers received contracts for three years, which were renewable for a further three years; thereafter, the individual must either obtain an indefinite contract or leave the organization. Indefinite contracts in practice usually went only to technicians and engineers and not to the research scientists, since the research men must return to their native country to teach the next generation.

An interesting problem was what, for an individual country, would represent a balanced proportion between national and international expenditure. In the case of nuclear physics, the United Kingdom's contribution to CERN represented about one-fifth of total British expenditure in the field. However, in the case of the smaller countries, most of the total national expenditure went to CERN. It followed that many of the smaller countries found it difficult to get their physicists back again from CERN after their term of duty. Moreover, an organization such as CERN is suited only to the more mature research worker, and national facilities will be needed in any event to train individuals to the point at which they can make a useful contribution to an international organization.

This left finally the political factors making for a favourable climate for international co-operation, and these would probably be common whatever the needs of the particular field. CERN had been formed at a time when there was a sense of togetherness among most of the nations of Western Europe, a feeling which sought for some practical expression. It was important that any concrete form which could be given to it should not be controversial, should not be military, should not be a political disaster if it failed and that success if achieved should be clearly recognizable. If these factors were present, the way was open for the scientists, who, after all, led the world in international co-operation, to exert pressure on their political colleagues. In this context great interest was shown in the French proposal for devotion of 0·5 per cent of national defence budgets to cancer research. The enormous sums of money which might become available if this proposal were put into practice led to the suggestion that its scope should be extended beyond the field of cancer research. This was the sort of political climate which one should seek and the individual factors which should operate. If these factors were absent, bureaucracy would find ways, means and doubtless good reasons for stifling the effort.

CHANGING ROLE OF SCIENCE AND TECHNOLOGY*

By Dr. JULIUS A. STRATTON

President of the Massachusetts Institute of Technology

THIS is the first time in forty-two years that the President of the Massachusetts Institute of Technology has been called on to deliver the Commencement Address. I am immensely honoured. Fortunately also I am untroubled by superstitions, for the last occasion of this kind on the campus ended in a terrible downfall. By chance that was also on a twelfth of June. The class of 1922 chose the Great Court for its Commencement exercises, and some two thousand people gathered under an enormous tent. That day was bright and clear, but during the morning the wind began to blow, and just as President Elihu Thomson, over the sound of flapping canvas, launched into his words of exhortation to the seniors, a tremendous gust struck the tent. The outer poles cracked, and slowly the roof began to settle down on the heads of the audience. With flying robes and skirts, the faculty, the students and their parents made their way out safely, and on the steps of the colonnade, under the dome, diplomas were finally delivered in delightful confusion. Only seldom does an orator succeed in bringing down the house—and almost never at Commencement time. Now, in a more serious mood, I speak to you, who are about to receive your degrees, not as a transient visitor on a strange campus, but as one who out of the experience of many years at this Institute has learned at first hand what it means to be a student here. You have worked hard for this moment. I know the pressures that have been upon you; the seemingly infinite demands on your capacity to learn; and the tremendous pace set by a quality of students that constantly challenges the faculty. I believe I know, too, something of the hopes of your families, of their pride in your achievement, and of sacrifices that have made your education possible.

---

* Substance of the ninety-eighth Commencement Address delivered at the Massachusetts Institute of Technology on June 12.

You came to us out of a most extraordinary diversity of origins and backgrounds. There is scarcely a State in the Union which is not home to some of you, and you represent countries in every part of the globe. You have grown up in many faiths and traditions. You have known both wealth and poverty. You have attended small schools and large, public and private, in country districts and in great cities.

Yet for all these differences, you brought with you a certain basic community of interests and abilities. You were moved by much the same hopes and ambitions. Some of you were directed toward engineering or science; others toward architecture, toward economics or political science, toward psychology or management. But all of you, I suspect, shared the same concept of what the Massachusetts Institute of Technology stands for in the world to-day and viewed in the same light the role of science and technology in human affairs.

Within the infinitely complex network of intellectual, emotional and spiritual forces which make up this strange body we call mankind, one may discern two primitive impulses that trace back to the beginning of time. The first is the desire to understand—the passionate quest for knowledge for its own sake—about the stars, about matter, about living things. The second is the urge to do, the drive towards action and mastery of our physical environment.

The systematic interpretation of Nature into a framework of law we call science; the effort to convert experience and understanding to useful account is engineering.

For countless centuries the quest for knowledge through science has been moving forward, slowly gathering momentum, while the engineer has provided shelter, assured our supplies of food and water, built our roads and bridges, and created our massive industrial technology. Now, suddenly—almost within your own generation—the whole sweeping line of advance seems to have taken fire. In some strange, unforeseen way, we have come to a critical threshold, beyond which the forces of technical progress appear to be self-sustaining. The processes of discovery, invention and production feed on each other. In every domain of the physical and biological sciences there is a bursting out into new fields and new theories. The translation of ideas into action is taking place at an ever-accelerating pace, so that the functional line of demarcation between scientist and engineer has almost vanished. From the factories and commercial laboratories of the United States pours a mounting stream of new products, new versions of old devices—from jet aeroplanes to transistor radios, from nuclear reactors to household appliances, from a multitude of new drugs to synthetic building materials. We are at the point of being overwhelmed by the very bulk of our accumulated information, bewildered by the diversity of our manufactures; and we are failing to-day to assess clearly the implications of these developments for to-morrow.

Yet through this maelstrom of scientific and technological enterprise runs the almost mystical conviction that somehow every technical advance will contribute ultimately to the good of society. Every responsible physicist believes intuitively or subconsciously that each new insight into the structure of matter will stir someone else—some engineer—to the development of a useful piece of hardware; and every engineer in turn expects that each new product or service will in some way add to our health, comfort and material well-being.

There is nothing new in this idea of technology as the driving force of progress. It is an idea which took form during the enlightenment of the eighteenth century and emerged from the Industrial Revolution of the nineteenth as a well-defined philosophy. The Massachusetts Institute of Technology has its historical roots in that concept of the usefulness of science. Nor is there any need for me to demonstrate how the advance of technology has improved the material condition of mankind.

Yet for all my own faith in, and dedication to, the work and methods of science, I do not believe that we can any longer afford to take such a thesis for granted; and I fear that a blind confidence in the inevitable good of material progress can lead only to disillusionment. The stupendous revolution of the twentieth century is doing more than adding theories, data, and apparatus to the accumulated store of the past. It has provided an entire new dimension to human affairs on a total change of scale.

To use words that you are particularly well qualified to understand, science, technology, and society now form a tightly coupled system. Each new technical advance adds a component to that system. In years gone by we have isolated these components and assessed their usefulness in terms of a specified purpose. We measured the value of a military weapon solely by a military requirement; a new drug by its immediate effectiveness in dealing with a particular pain; a new highway simply by the number of cars it carried; or a chemical waste disposal plant by the interests of local inhabitants. But now, because such components are coupled into an immensely complex system on a huge and massive scale, it is only by an examination of the impact on society as a whole that we can pass judgment on the degree of progress.

To draw on a biological analogy, I am saying that we must advance from the anatomy of components to the physiology of the organic whole—which indeed is now the society itself. One may prescribe an aspirin for a headache or build a turnpike to ease a traffic jam. But the headache may be merely an isolated symptom of a deeper disorder—a disease which may be identified only by a diagnosis which itself is the product of many specialists working together. So, too, our society—the body politic—is subject to old, chronic disorders and to new ailments. These diseases of the system are emerging in increasing number; and we must be courageous in recognizing that they are themselves the by-products of our highly technological environment.

Consider the transformation of our cities—the physical and often social degradation of large areas—the loss of serenity and beauty. We have never before produced so many cars or such fast aeroplanes; yet transportation in the United States is rapidly approaching a point of crisis. The shift to automation in industry is accelerating and will have profound effects on the character of our labour force, on its training, and on its security. We are polluting our air and our water. The pesticides which we are using on a mounting scale are a boon to agriculture but a threat to our natural resources. We find extreme poverty in the midst of affluence. The problem of the economically deprived citizen; be he coloured or white, is one of training and education to cope with a highly technological and rapidly changing society.

These are but a few examples. I could cite many more —all too large, too complicated, too sophisticated to be conquered or even arrested by sporadic investigations and isolated research projects. Of course, science has generated these problems, and we can be equally confident that science can help us to alleviate and resolve them. But our efforts must now move to a higher plateau. We can no longer afford to nibble away piece by piece at the problems of the modern city—of transportation, of underdeveloped economies, of automation, or of disarmament. We indulge excessively in unco-ordinated conferences, surveys, and studies that on the whole are highly unproductive. Our ailments are vast and complex, and they will yield only to planned, collaborative attacks focused on clear objectives and leading to concerted action.

One of the charges which has been most commonly levelled against science is that progress is leading increasingly to the fragmentation of knowledge and the proliferation of a multitude of specialities. But these great new socio-technical problems and the systems they represent are now also generating strongly countervailing forces toward new unities, bringing together many different resources, and giving rise to a new synthesis of knowledge. For in every instance success will depend on the joint contributions of the physical and biological scientists, of economists and political scientists, of engineers and architects, of historians and philosophers. The task of articulating or welding together these components of learning into systems of understanding offers the highest intellectual challenge of our time.

As I have reflected on these matters—as I have pondered about how all this is to be accomplished and where—it has seemed to me that there exists nowhere at the present time any one institution or specific kind of organization which is in a position to undertake alone this monumental task. There is to my knowledge no single agency of government which has the necessary diversity of resources and the freedom of action. By their very character these problems lack the motive of profit which is the essence of private enterprise; and because they lead inescapably from the intellectual domain into the field of action, they present definite risks and perils for the university.

Yet it is only within the framework of the modern university that one finds the wide range of interests, a common ground for the exchange of ideas, a forum of discussion for scholars who draw on the arts and the humanities as well as on science and engineering. This is particularly true of an institution of the character of the Massachusetts Institute of Technology. I do not believe that we can escape the responsibility of taking part in the solution of problems which touch most deeply on the welfare of our society. In the synthesis of knowledge, as well as in the creation of new learning, we must lead the way: and though at times we shall find ourselves drawn more deeply into the main stream of contemporary affairs, we shall continue in the process to educate with relevance to our age. This has indeed been our historic mission.

I have wanted in these few remarks to give a broader and perhaps a new insight into the changing role of science and technology. The essence of this change lies not so much in the expanding scale of discovery and application; it lies rather in the complete penetration of science and technology into every domain of human affairs. But principally it must be understood that these developments have brought a new order of responsibility for the consequences of progress to our society as a whole. Some of this responsibility falls on our institutions—on government, on industry and on the university. But in a free society the burden of obligation rests ultimately on the individual. You are in a superlative position to meet the technical challenges of our day. But you owe something more to the common account. You must be ever mindful of your own deepening responsibility, both to the profession you have chosen to follow and to the society which will look to you for positive action. Your life will be productive in proportion to the goals that you achieve; rewarding in proportion to your commitment to all that is of value; and full in the satisfaction that the world will be better for your efforts.

NEWS and VIEWS

Experimental Physics in the University of Liverpool: Prof. L. L. Green

Dr. L. L. Green, reader in the Department of Physics, has been appointed to the newly established chair of experimental physics in the University of Liverpool. Dr. Green was educated at Alderman Newton's School, Leicester, and at King's College, Cambridge, where he graduated B.A. in the Natural Sciences Tripos in 1944 and gained a Ph.D. in 1948. From 1944 until 1946 he was employed by the Department of Tube Alloys at the Cavendish Laboratory, Cambridge, where from 1946 until 1948 he held a Department of Scientific and Industrial Research research studentship. In 1948 he was appointed assistant lecturer at the University of Liverpool and later held the posts of lecturer, senior lecturer and reader. Dr. Green has lectured on nuclear reactions at conferences organized by the Physical Society and the Argonne National Laboratory and the Universities of Yale, Pennsylvania and Strasbourg. His published work has been mainly concerned with nuclear structure physics. Dr. Green will take up his duties on October 1.

Theoretical Physics in the University of Hull: Prof. G. H. A. Cole

Dr. G. H. A. Cole has been appointed to the newly established chair of theoretical physics in the University of Hull. Dr. Cole is thirty-six years of age and graduated at University College, London, with first-class honours in physics in 1949. He obtained his Ph D. in Queen Mary College, London, in 1952, and the D.Sc. of the University of London in 1963. For a time he was a scientific officer in the Royal Naval Scientific Service and then returned to take up an Imperial Chemical Industries fellowship in University College, London. He left there in 1957 to take up a visiting assistant professorship in the University of California for a year. Since then he has held the appointment of senior theoretical physicist and executive of Clarke, Chapman and Co., Ltd., marine, mechanical and electrical engineers, of Gateshead, Co. Durham. Dr. Cole's major interests have been in the fields of fluid dynamics, statistical mechanics of equilibrium and non-equilibrium fluids and of plasmas.

Physical Metallurgy in the University of Liverpool: Prof. D. Hull

Dr. D. Hull, senior lecturer in the Department of Metallurgy in the University of Liverpool, has been appointed to the newly established chair of physical metallurgy. Dr. Hull, who is thirty-three years of age, was educated at Baines Grammar School, Poulton-le-Fylde, and at University College, Cardiff, where he was awarded the degree of B.Sc. with first-class honours in metallurgy in 1953, and the degree of Ph D. in 1956. In 1954 he was awarded a Students' Essay Prize of the Institute of Metals, and in 1955 the second prize in the British Association for the Advancement of Science Endeavour Competition. During the period 1956–60 he was employed in the Metallurgy Division of the Atomic Energy Research Establishment at Harwell and the Clarendon Laboratory, University of Oxford, being appointed scientific officer in 1956, and senior scientific officer and section leader in 1958. From 1959 until 1960 he was secretary of the Basic Properties Committee of the Inter-Services Metallurgical Research Council. He was appointed lecturer in metallurgy at the University of Liverpool in 1960 and senior lecturer in 1961. He has been a member of the Basic Properties Committee of the Inter-Services Metallurgical Research Council since 1961. He has acted as consultant to Manlabs, Cambridge, Massachusetts, to the Atomic Energy Authority and to the International Research and Development Co., Ltd.

Mathematical Statistics in Monash University: Prof. P. D. Finch

Mr. P. D. Finch, who is thirty-four years of age, has been appointed professor of mathematical statistics in

Monash University, Victoria, Australia. After graduating at the University of Durham he served in the Royal Air Force and was later a senior research officer in the Research Techniques Unit at the London School of Economics, a senior lecturer at the University of Melbourne, and a Fellow in the Department of Statistics at the Australian National University, Canberra. He has written many papers on queueing theory and has lately directed his attention to problems of statistical inference. His appointment at Monash will strengthen an already vigorous school headed by Profs. K. C. Westfold and G. B. Preston.

Second Chair of Geography in the University of Birmingham : Prof. H. Thorpe

DR. H. THORPE, at present reader in historical geography in the University of Birmingham, has been appointed to the newly established second chair of geography from October 1. Dr. Thorpe was born in Derbyshire in 1913, and from Chesterfield Grammar School gained an exhibition to the University of Durham in 1931. There he graduated with first-class honours in geography and was awarded the Maltby Prize for the best thesis presented in ancient history and archæology. After graduation he remained at Durham as demonstrator in the Department of Geography, and was awarded an M.Litt. degree for a thesis on rural settlement in 1936. During the Second World War he served with the Survey Branch of the Royal Engineers, first in the European theatre and then in south-east Asia, where he became senior survey officer, Malaya. After the War he was appointed lecturer in geography in the University of Birmingham, but continued to command 529 Field Survey Squadron, Royal Engineers (Territorial Army), for the Midlands until 1958. He has remained in the University of Birmingham ever since, being promoted senior lecturer in 1951, and given the title of reader in historical geography in 1954. Over many years he has directed his principal research to the elucidation of the evolution of the landscape of the West Midlands and especially of Warwickshire over the past five or six centuries, and the reconstruction of the geography of the area at certain periods in the past. Dr. Thorpe's monograph on the City of Lichfield, published a dozen years ago in the Staffordshire Historical Collections, may be known to some, and his volume on *The Printed Maps of Warwickshire, 1576–1900*, written in collaboration with Mr. Paul Harvey of the British Museum, is a model of its kind. Dr. Thorpe has two comparable volumes in hand, the first on *The Printed Maps and Plans of Warwickshire* and the second on *The Printed Maps of Worcestershire, 1577–1900*. Dr. Thorpe is a well-known figure in geographical planning and archæological circles in Birmingham and the West Midlands. He is chairman of the Birmingham Branch of the Geographical Association, and vice-president of the Birmingham Archæological Society.

New University at Stirling, Scotland

ON the advice of the University Grants Committee, the Government has agreed to establish a new Scottish university at Stirling. The site recommended by the University Grants Committee is the Airthrey Estate, which is at present owned by the Scottish Home and Health Department. The preliminary steps for planning the new university will begin at once and the University Grants Committee will be in close consultation with the sponsoring Committee at Stirling. The target for student numbers recommended by the Robbins Committee for 1967–68 will be met by expansion of the existing universities. The object will therefore be that the new university should be planned so as to enable it to make a growing contribution to the need for university places in the latter half of the ten-year programme envisaged by the Robbins Committee. Stirling will be the eighth new university foundation to be established in Great Britain in the past five years. In recent weeks, also, the Royal College of Science and Technology at Glasgow has been granted a charter and has become the University of Strathclyde. The new university at Stirling will therefore be the sixth in Scotland.

Overseas Students in Britain

A LEAFLET issued by the Association of Commonwealth Universities gives the total number of students from other countries enrolled for full-time study or research in United Kingdom universities in 1963–64 as 14,117, compared with 14,020 in 1962–63, and 13,385 in 1961–62. Of these, 8,280 were from other parts of the Commonwealth and 5,837 from non-Commonwealth countries; 313 were in agriculture and dentistry; 3,310 in arts; 128 in dentistry, 1,965 in medicine, 2,448 in science, 2,574 in social studies, 3,269 in technology, and 110 in veterinary science. Postgraduate students totalled 6,926 and 6,858 held an award of some kind. India sent 1,543, the United States, 1,295, Nigeria, 1,022, Pakistan, 749, Canada, 652, Iraq, 530 and Egypt, 452.

International Survey of Scientific and Technical Personnel

THE June 1964 issue of the *O.E.C.D. Observer*, besides an article on the co-ordination of foreign aid, summarizes the findings of the *Third International Survey of Scientific and Technical Personnel*, recently published by the Organization for Economic Co-operation and Development under the title "Resources of Scientific and Technical Personnel in the O.E.C.D. Area". The Survey provides no answer to the question whether some countries are over-investing in education while others are neglecting it. Moreover, the general correlation between gross national income and educational efforts in member countries of the Organization for Economic Co-operation and Development does not suggest a final answer to the question as to the optional reserve allocation to education in individual countries. Whereas in Britain about 90 per cent of new entrants obtain a first degree, in some other countries, including the United States, only 50–60 per cent of university entrants do so, and while, in Italy, France, Germany and Britain, more than 80 per cent of secondary school leavers qualified for admission to higher education in the United States and some other countries the proportion was 50 per cent or less. The proportion of university graduates qualifying in engineering, science and agriculture varied from 75 per cent in Austria to 20 per cent in the United States and 15 per cent in Greece. The output of scientists in Western Europe is increasing much more rapidly than that of engineers. The number of scientists and engineers, excluding technicians, in member countries of the Organization for Economic Co-operation and Development in 1959 was 2·6 million and is expected to increase 6–7 per cent in the early 1960's.

The Lace Research Association

THE fifteenth annual report of the Lace Research Association, for 1963, refers to the complete change in the basis of membership with the abandonment of the levy, with the effect that the work of the Association is directed much more towards the interests of the Leavers makers, Leavers and Raschel finishers and Leavers and Raschel dyers providing the basic income (Pp. 22. Bilborough, Nottingham: The Lace Research Association, 1964). In the investigation of the packing density of the yarns wound into brass bobbins, a special technique has been developed to fix the yarns in position by 'potting' them in resin before a cross-section of the bobbin is made. Work has been initiated on a device to provide an automatic dropping in of bobbin threads on the brass bobbin winder. Steady progress was made in supplying and fitting beam-thread-breakage detectors on Leavers lace machines and further development work was undertaken with the prototype equipment for detecting holes appearing in the lace due to thread breakage, which is designed to traverse and scan the facing bar. The development of the mechanical pre-cutter has further advanced, and various types of scalloping machines have been investigated for their suitability in handling Leavers' lace. In dyeing Bourdon cord, the affinity of the dye was found to have an important effect on penetration into the core, but the nature of the cord and greasiness of the core also affect the penetration of the dye liquor. No significant advances in the examination of new flame-proofing materials and methods for their suitability for lace were made during the year.

The American Philosophical Society

Year Book 1963 of the American Philosophical Society includes a brief history of the Society, a list of officers since 1769, biographical memoirs, among which are those on N. H. D. Bohr, Lyman J. Briggs, Sir Charles Darwin, Sir Richard W. Livingstone, and reports on meetings during the year (Pp. 738. Philadelphia: The American Philosophical Society, 1964). The reports of standing committees include that on research, recording: 240 grants totalling more than 250,000 dollars approved in 1963 from the Penrose Fund; 65 grants totalling 62,000 dollars from the Johnson Fund; awards of four fellowships totalling 29,000 dollars from the Dallas Fund for research in clinical medicine. Besides these lists of grants, the Committee's report includes notes on the progress of investigations by the recipients of grants. The *Year Book* also includes a list of members, and reports on finance.

Petroleum Consumption in the United Kingdom in 1963

Compared with 1962, the final figures published by the Petroleum Information Bureau on behalf of the United Kingdom Petroleum Advisory Committee show that the demand for petroleum products in 1963 totalled 55,692,382 tons, an increase of 9·4 per cent on the previous year (*U.K. Petroleum Industry Statistics: Consumption and Refinery Production, 1962 and 1963.* Pp. 8. London: Petroleum Information Bureau, 1964). This is exclusive of bunkers for ships engaged in foreign trade. With one exception, white spirit, deliveries into consumption of petroleum products in the United Kingdom record substantial increases. Consumption of motor spirit was up by 5·6 per cent; industrial spirits (including industrial benzole) rose by more than 7,000 tons; white spirit showed a drop of 2,614 tons; demand for kerosine (burning and vaporizing oils) was more than 200,000 tons greater than in 1962; Derv (Diesel engined road vehicle) fuel increased by 8·7 per cent. Total deliveries of black oils (gas/Diesel and fuel oils) rose by 8·5 per cent. Due mainly to substantial increases in consumption by railways, construction industry, domestic appliances, metal industries and more recently the electricity industry, gas/Diesel oil demand rose by 18·1 per cent. Temperature was largely responsible for boosting burning-oil deliveries by 16·9 per cent, having regard to the severe winter conditions in the year under review. For the rest, deliveries of lubricating oils and greases increased by 3·7 per cent, bitumen supplies by 6·2 per cent, liquid gas by 60 per cent, due largely to growing demand by the Gas Boards, the latter authorities also being responsible for a 26 per cent increase in distillate feedstock and a 24 per cent increase in refinery gas offtake. As in recent years, the demand for chemical feedstock, now a major product of the oil industry consequent on the remarkable growth in the field of petrochemicals, rose by 38·9 per cent. Thus the overall picture is one of steadily increasing demand for petroleum products in Britain, a tendency which is world-wide, one likely to persist for many years to come; notwithstanding known petroleum resources, of which the Middle East would at present appear to possess the lion's share, in this context the intensive exploration activities of the oil companies everywhere are clearly justified.

International Bird Preservation

The 1963 annual report of the British Section of the International Council for Bird Preservation again stresses the widespread dangers resulting from the indiscriminate use of pesticides, and the urgent need for Government control (Pp. 29. London: The International Council for Bird Preservation, c/o British Museum (Natural History), 1964. 3*s*.). There has been encouraging progress in the campaign against oil pollution of the sea, several more countries, including the United Kingdom, having accepted the 1962 amendments to the 1954 Convention for the Prevention of Pollution of the Sea by Oil. There have also been additional adherents to the original Convention. The great mortality among birds during the bitter winter of 1962–63 evoked measures for special protection in many European countries, and in Great Britain the previously legal taking of eggs of certain common species was made an offence. The increase in activities of armed hooligans and the acquisition and use of dangerous weapons by irresponsible persons is causing much concern, and the British Section is in consultation with the National Farmers' Union about the possibility of introducing further legislation to deal with this problem. Sweden ratified the International Convention for the Protection of Birds, Paris, 1950, in March 1962, and it is earnestly hoped that the United Kingdom will also take this step.

National Parks in South Australia

An illustrated handbook describing national parks and wild-life reserves of Australia has been published by the Commissioner (*South Australian National Parks and Wild Life Reserves: An Account of the National Parks and Reserves situated near Adelaide, South Australia.* Edited by Bernard C. Cotton. Pp. 160 (16 plates). Adelaide: Government Printer, 1964). All the parks and reserves are within easy reach of Adelaide and the handbook not only describes how they have come into being but also provides considerable detail about the main features of each park and reserve. Plants and animals peculiar to Australia are given special prominence. The handbook also describes the pleasure resorts controlled by the Tourist Bureau. There are many useful black-and-white illustrations and some outstanding colour photographs.

The Western Australian Museum

The annual report of the Western Australian Museum for 1962–63 records that in the research collections work has continued in modernizing the accommodation (Pp. 41. 7 plates. Perth: Government Printer, 1963). In particular, the installation in the basement of fire-resistant rooms with automatically operating carbon-dioxide flooding systems for the spirit-preserved and naphthalene-saturated zoological collections has been completed. In research, members of the staff have continued to make known the results of their work through publication in specialist journals. Co-operation with other museums and organizations at an international level is becoming more frequent. Modernization of the Museum buildings has continued in the completion of the remodelled entrance hall. The Museum has had no addition to permanent buildings since 1899 and the Museum Board has made a strong appeal to the Government to implement a decision made in 1958 to build an extension to the James Street Building.

New Zealand Earthquakes, 1958–59

The network of seismological stations centred on the Seismological Observatory, Wellington, New Zealand, had in 1958 and 1959 seventeen members. These stretched from Apia (13° 48·4′ S., 171° 46·5′ W.) in the north to Scott Base (77° 51·0′ S., 166° 48′ E.) in the south. The organization of the instruments fell into two sections.

First, there were the short-period seismographs distributed widely in New Zealand, and intended to yield records of earthquakes originating in the country. Secondly, there were the teleseismic instruments to provide records of distant earthquakes. These functions, however, interlocked, and every seismograph gave some useful information in both categories. The discontinuance of recording at New Plymouth in 1958 left the network somewhat critically dependent on the operation of the station at Tongariro, but the standard of coverage was successfully maintained. The *New Zealand Seismological Reports* for 1958 and 1959 give details of the installations at all the stations together with timing arrangements and the readings of the seismograms. Further, there is a list of instrumentally determined epicentres, an index of felt earthquakes, and a list of staff together with a note of their publications during the two years.

The principal New Zealand earthquakes of 1958 and 1959 are discussed in the *Reports*, and maps are given showing: (1) epicentres of normal earthquakes; (2) epicentres of deep-focus earthquakes; (3) isoseismals for some earthquakes. In 1958 the level of earthquake activity in New Zealand was low: 55 earthquakes were reported felt only in North Island, 15 only in South Island and 6 in some parts of both Islands. In 1959, 58 earthquakes were felt in North Island only, 19 in South Island only, and 5 in some parts of both Islands. On May 22, 1959, a large shallow shock with magnitude 6 and an epicentre in the Marlborough Sounds region caused as much damage as any shock in New Zealand since the Wairarapa earthquakes of 1942. Picton suffered most severely. In all, some 460 insurance claims were lodged with the Earthquake and War Damage Commission. These mainly concerned old property. Two shallow shocks had magnitude 5·5, but reported intensities from them did not exceed *MM*4. On the other hand, a shock of magnitude 4·8 on July 30, 1959, centred some 20 miles north of Marton, gave rise to 40 insurance claims for damage in the Wanganu district.

Dry-acid Descalers for Oil Wells

CARBONATE scale is frequently a serious factor in inhibiting flow of oil to the pumps in oil wells, especially those past peak production but economically active and where water is produced along with the crude oil. After a time, scale builds up and clogs the perforations at the bottom of the casing, gradually restricting the flow of oil from the surrounding reservoir rock. Until recently the time-honoured practice of pumping hydrochloric acid into the well to remove this scale was customary, but this often involved long-distance delivery in tank-trucks to remote pumping sites, was costly, and frequently hazardous to the oilmen concerned. Much research into the possibility of using a 'dry-cleaner' descaler has been rewarded by the discovery and commercial production of an easy-to-handle compound based on sulphamic acid. This is packaged in 100-lb. drums and is known as 'Visco 900', according to a recent issue of the *Dupont Magazine* (58, No. 2; March–April 1964). The Nalgo Chemical Co.'s Visco Division, Sugar Land, Texas, began marketing 'Visco 900' in early 1961, and the response from oilmen has been very favourable. In 1960, Du Pont approached the Nalgo Chemical Co. with the idea of using inhibited sulphamic acid. After testing sulphamic with Visco Division's additives for nearly a year, a suitable dry-acid cleaner was found. Many practical advantages are claimed for these sulphamic-based descalers, among which are: reduction in costs in equipment and labour; in many cases a 'slug' of the compound, dry or in slurry form, is added at the well-head, displaced by the pump to perforation level, and left to do its work without further attention; shipping and handling dry; convenient storage at well-site; no fume damage to equipment or personnel; non-irritating to unbroken skin; easy removal by washing off with water, etc. Examples of the results of this dry-acid descaling treatment are given in the article, one of which happened at the Standard Oil Co. of Texas oilfield near Sivells Bend, Texas; output of two pumping wells had dropped to 17 and 21 barrels per day, respectively; after cleaning with 'Visco 900', following pretreatment with 'Visco 1111' (a surfactant), at the end of a 17-day period, the first well increased production by 10 barrels, the second by 15 barrels per day. Water-injection wells, used for pumping water back to re-pressure the oil reservoir and flush the oil ahead of it to adjacent wells, and salt-water disposal wells, likewise have their scale-plugging tendencies; here again the use of the sulphamide-based descaler has met with success.

Jacobian Elliptic Functions

VOLUME 7 of the series of *Mathematical Tables* issued by the National Physical Laboratory, Teddington, consists of tables of Jacobian elliptic functions the arguments of which are rational fractions of the quarter period (Department of Scientific and Industrial Research: National Physical Laboratory. *Mathematical Tables*, 7. By A. R. Curtis. Pp. iii+81. London: H.M.S.O., 1964. 15*s*. net). They were prepared in order to facilitate computations occurring in a method of filter design described by S. Darlington (*J. Math. Phys.*, 18, 257; 1939). The 70 pages of tables list the functions $sn\left(\frac{mK}{n},k\right)$, $cn\left(\frac{mK}{n},k\right)$ and $dn\left(\frac{mK}{n},k\right)$ to 20 decimal places for integral values of n from 2 to 15 inclusive, and for m up to $(n - 1)$. In place of uniform intervals of k or $\sin^{-1}k$, Jacobi's nome q, related to k by $q = \exp(-\pi K'/K)$, is used. Equally spaced values of q correspond to a k-distribution which is very dense in the region close to $k = 1$. The range covered by the tables is $q = 0$ to $0 \cdot 35$ at intervals of $0 \cdot 005$, corresponding to $k = 0$ to $0 \cdot 99933$. . . . The calculations were performed using the *Deuce* computer, and the programmes and method used are described in the introduction to the tables. An alternative method of construction of the tables, which is perhaps more convenient when k is used as argument, is also outlined.

Use of Red Phosphorus as a Fertilizer

THE potential use of red phosphorus as a fertilizer has been investigated by H. P. Rothbaum, of the Dominion Laboratory, Department of Scientific and Industrial Research, Wellington, New Zealand (*New Zealand Journal of Science*, 7, No. 1; March 1964). The oxidation rate of red phosphorus in four moist soils of different phosphate-retention capacity has been examined and the reaction is shown to be chemical, almost independent of phosphorus/soil ratio, and dependent on temperature, particle size, and the presence of catalysts. The products of oxidation are phosphites and phosphates. Explosion hazards of red phosphorus in superphosphate have been investigated, and the results suggest that mixtures can be made which would be safe and economic long-term fertilizers, with the possibility of reducing phosphate fixation. Small amounts of copper may be useful in regulating the rate at which red phosphorus becomes available. Together with W. Tuft, Rothbaum has also made extended investigations on oxidation rate of red phosphorus. Chemical methods of estimating small amounts of red phosphorus in soils have been developed. The rates of oxidation of red phosphorus in moist and in dry soil, obtained by using chemical methods, were shown to be consistent with results obtained by using radioactively labelled phosphorus. The chemical method also demonstrated that the rates of oxidation determined by radioactive methods apply over longer periods. The rate of oxidation of red phosphorus alone in air was also determined; it was found to be slower than in soil and unaffected by the presence of water.

Handling, Processing and Packing Dates

It has been estimated that at least 1 million people are supported entirely by date cultivation, and in view of the nutritional value of this fruit, particularly in the diet of many people in the Middle East, the recently published Food and Agriculture Organization Development Paper, No. 72, will be of considerable interest, especially as hitherto there has been no single publication dealing with the processing of dates (*Dates : Handling, Processing and Packing*. Pp. xxiv + 392. Prepared by V. H. W. Dowson and A. Aten. Rome: Food and Agriculture Organization of the United Nations; London: H.M.S.O., 1962. 20*s*.; 4 dollars). Much of the information concerning the various operations to which the date may be subjected after harvesting has been provided by workers actively engaged in the date industry and should be of particular interest to several countries where attempts are being made to improve the quality of the fruit. Knowledge of the composition and changes which constitute ripening is essential in the processing of dates, as is that of the different varieties, and these subjects have all received full attention from the authors. Gathering and modern packing-house procedures, including the equipment used, are described in detail. In the appendix, information is given of various analytical methods used to examine dates and of the standards used to evaluate their quality. There is also a most comprehensive explanatory list of the Arabic words so widely used by the date industry. The Paper is freely illustrated; the coloured plates showing the development stages in the Beiyuudhi date of Libya are of a particularly high standard. It is perhaps a pity in a work of this standard that such a number of minor errors have occurred in the text, resulting in the inclusion of a rather depressing corrigenda sheet. Nevertheless, as a reference work this Paper will be of great value to all who are interested in the date.

Neuropharmacology

The January issue of *The Practitioner* (19, No. 1147; 1964) deals with neuropharmacology. The reason for the choice is that in no branch of therapeutics have there been more advances than in this. The introduction of the so-called 'tranquillizers' opened up a fascinating new approach to the management of mentally and emotionally disturbed patients. Many of the original claims for this new group of drugs were over-optimistic, but the basic concept was sound. This is clearly exemplified in several of the articles. Almost equally impressive has been the progress achieved in the fields of anti-convulsants and anti-Parkinsonian drugs, but here, as in the case of tranquillizers, the multiplicity of these new preparations has proved a handicap to the general practitioner. To decide which of them is best for his individual patients is proving an ever-recurring problem, and it is hoped that the advice provided in this special issue of *The Practitioner* will prove of real value. Other articles deal with therapeutic problems that the practitioner is liable to encounter.

Fœtal and Infant Liver Function and Structure

All scientists are already greatly indebted to the New York Academy of Sciences for the well-known series of articles published in its *Annals*. The recent publication entitled *Fetal and Infant Liver Function and Structure* contains the forty papers presented to a conference called for the purpose of bringing together numerous papers on the function and structure of the fœtal liver that have been published (Vol. 111, Article 1. Pp. 1–558. New York: New York Academy of Sciences, 1963. 7 dollars). The papers given to the conference are classified under seven major sections: Part 1, "Morphology", contains six papers on the structure, growth and regeneration of the liver; Part 2, "Physiology", contains five papers on the physiology of the liver in the fœtus, new-born infant and chick embryo; Part 3, "Chemistry", contains seven papers on the chemistry of the formation and action of various enzymes; Part 4 contains papers devoted to bilirubin and its related compounds; Part 5, "Pathology", contains six papers on the pathology of various diseases of the liver; Part 6 contains seven papers discussing the clinical problems of jaundice in early infancy and those of biliary atresia; Part 7, "Discussion Workshop", reports discussions on various subjects, such as terminology, regeneration, enzymes, morphology, circulation, neonatal chemistry, bilirubin conjugation, problems of pathology and clinical problems. Edited by Harold E. Whipple with Julian A. Sterling as consulting editor, these contributions by 82 authors together provide a valuable and factual epitome of the present-day knowledge of this subject.

Television Society Premiums

The Television Society has awarded the following Premiums for outstanding papers read before the Society in 1962–63: *The Mullard Premium* to Mr. G. B. Townsend (Rank-Cintel Ltd.), for his paper on "New Developments in SECAM"; *The Wireless World Premium* to Dr. P. Schagen (Mullard Research Laboratories), for his paper on "Electronic Aids to Night Vision"; *The Electronic Engineering Premium* to Mr. A. C. Dawe (E.M.I. Electronics Ltd.), for his paper on "Characteristics of Special Vidicon Camera Tubes and their Applications"; *The Pye Premium* to Mr. K. Fawdry (B.B.C.), for his paper on "Education by Television"; *The T.C.C. Premium* to Mr. C. F. Whitbread (Associated Aerials Ltd.), for his paper "Receiving Aerials for U.H.F. Television".

The Royal Society of New Zealand

The *Proceedings of the Royal Society of New Zealand* for April 1964 (Vol. 91, Part 1) includes the report of the tenth New Zealand Science Congress, with reports of the half-yearly meeting of the Society, 1962, and of the annual and half-yearly meetings, 1963. In his presidential address, Dr. C. A. Fleming, discussing the promotion of science in a Commonwealth democracy, reviews the formation and growth of the Society. He notes particularly the consistent desire of the Council during the past 25 years to become more representative of New Zealand science by some kind of liaison with the increasing number of national scientific bodies serving a particular discipline, the desire that the fellowship should adequately represent the balance of science in New Zealand, and the desire that Fellows should play a more active part in the Society's affairs. He suggests that three changes in the fellowship rules are desirable. Scientific eminence should be the sole criterion for nomination, but all nominees should agree to pay, if elected to the fellowship, a substantial annual fee towards the Society's administrative expenses. The right of nominating Fellows should be extended to groups of the Fellows themselves. The issue also includes Prof. H. Barraclough Fell's Hudson Lecture for 1962: "Saint Cuthbert's Birds and Thunderstones: Sidelights on the Search for Living Fossils".

University News :

Belfast

The following appointments to lectureships have been announced: Dr. M. G. Burnett (physical chemistry (supernumerary)); K. G. Proudfood (plant genetics); Dr. R. M. Pengelly (applied mathematics (digital computing)); Dr. D. L. Smith (botany).

Birmingham

The following appointments have been made: *Lectureships*, Mr. B. Ahamad (econometrics and social statistics); Dr. N. Cottingham (mathematical physics); Mr. B. D. Giles (meteorology and climatology); Dr. L. A. Griffiths (physiological chemistry); Mr. E. Stones (educational psychology). *Research Fellowships*, Mr. A. Ball (physical metallurgy); Mr. P. F. Barker (geology); Mr. J. H. Croft (genetics); Mr. D. J. Dunn (electronic and electrical engineering); Mr. A. G. Fraser (geology); Mr. J. G. Gardiner (Racal Research Fellow in the Department of Electronic and Electrical Engineering); Mr. N. L. Hancox (physics); Mr. W. J. Harvey (pure mathematics); Mr. G. E. Hollox (physical metallurgy); Dr. B. R. Pollard (mathematical physics); Mr. A. Pramnik (Imperial Chemical Industries Research Fellow in the Department of Electronic and Electrical Engineering).

Bristol

Dr. W. Chester, reader in applied mathematics, has been appointed to a chair of applied mathematics. Dr. H. E. Hinton, reader in entomology, has been appointed to the chair of entomology; Dr. F. Coles Phillips, reader in petrology, has been appointed to the chair of mineralogy and petrology. The following appointments to lectureships have been made: Mr. J. B. Bowes (anæsthetics); Dr. J. B. Chappell (biochemistry); Mr. P. B. Garland (biochemistry); Mr. E. M. McKay (electrical engineering); Mr. H. I. H. Saravanamutto (mechanical engineering); Dr. K. A. Upton (civil engineering); Dr. J. Wilks (education).

Edinburgh

The following have been appointed to lectureships: Dr. M. D. Wynne (chemical engineering); Mr. D. I. Campbell (education); Mr. H. Hastie (veterinary practice).

Newcastle upon Tyne

The Rev. Dr. E. E. Aynsley has been appointed to a professorship in chemistry. Other appointments are as follows: *Readerships*, Dr. R. J. T. Pennington (neurochemistry in the Department of Clinical Biochemistry); Dr. M. Fleischmann (physical chemistry); Dr. F. J. McQuillan (organic chemistry). *Lecturers*, N. Laws (applied mathematics); Dr. A. M. Mearns (chemical engineering). Dr. Mary Richardson has been reappointed Junior Luccock Research Fellow in the Department of Physiology for a further year.

Sheffield

The title of reader has been conferred on Mr. I. S. Maxwell (historical geography) and Mr. J. Crangle (physics). The following appointments have been made: *Lectureships*, Mr. J. F. Archer (bacteriology); Mr. D. J. Goldstein (human biology and anatomy); Mr. D. P. Rose (chemical pathology). *Research Fellowships*, Dr. K. H. Swinden (metallurgy).

Sussex

The University of Sussex has received a donation from the Bata Shoe Organization to enable it to establish a unit in the School of Social Studies for the study of race relations with particular reference to the Caribbean, West Africa and Brazil. The first director of the unit, with the title of Professorial Fellow, will be Mr. L. F. Henriques, at present lecturer in social anthropology in the University of Leeds.

Announcements

Prof. G. M. Badger, professor of organic chemistry at the University of Adelaide, has been appointed to the Executive of the Commonwealth Scientific and Industrial Research Organization. His appointment fills the vacancy caused by the death of Dr. S. H. Bastow in January.

An informal open meeting of the Physical Biochemistry Group of the British Biophysical Society on "The Use of Electron Spin Resonance Spectroscopy in Biological Studies" will be held in King's College, London, on September 17. Further information can be obtained from Dr. A. R. Peacocke, St. Peter's College, Oxford.

An informal discussion on "The Electrical Double Layer in Surface and Colloid Chemistry", arranged by the Faraday Society, will be held in the University of Bristol during September 21–22. Further information can be obtained from Dr. R. H. Ottewill, Department of Physical Chemistry, University of Bristol, Woodland Road, Bristol 8.

A course of lectures and practical instruction in "Teratology", intended primarily for medical and scientific graduates working in the pharmaceutical industry but open to others, will be held in the University of Cambridge during September 21–25. Further information can be obtained from Dr. D. H. M. Woollam, Department of Anatomy, The University, Cambridge.

The third European symposium on "Chemical Reaction Engineering" will be held, under the auspices of the European Federation of Chemical Engineering, in Amsterdam during September 15–17. The theme for the symposium will be "The Confrontation of Science and Practice in Chemical Process Development". Further information can be obtained from Dr. J. Hoogschagen, c/o A.K.U.N.V., Welperweg 76, Arnhem.

The Autumn Meeting of the Institute of Metals will be held in Harrogate during September 21–24. The programme will include discussions on: metals versus plastics; the application of modern concepts of metal physics to the development of creep-resistant alloys; hot-rolling of non-ferrous metals; the structure of eutectics. Further information can be obtained from the Institute of Metals, 17 Belgrave Square, London, S.W.1.

A meeting, organized by the European Branch of the Organic Geochemistry Group of the Geochemical Society, will be held in Paris during September 28–30. The first day of the meeting will be devoted to organic matter in rocks, and the following days to other natural organic materials. Further information can be obtained from Dr. M. Louis, Institut Français du Petrole, 1 et 4 Avenue de Bois Preau, Rueil-Malmaison (S. et O.).

A conference on "Luminescence", arranged by the Institute of Physics and the Physical Society, will be held in the University of Hull during September 15–17. The programme will include sessions on: the theoretical aspects of luminescence; electroluminescence; cathodoluminescence; phosphor preparation; single crystal growth; organic phosphor systems; luminescent materials for lasers. Further information can be obtained from the Administration Assistant, the Institute of Physics and the Physical Society, 47 Belgrave Square, London, S.W.1.

The seventh international Mineral Processing Congress will be held in New York City during September 20–24. The programme will include sessions on: comminution; gravity and dense-media separation; magnetic and electrical separation; surface chemistry in mineral processing; flotation kinetics; chemistry of flotation; flotation practice; chemical processing; automation and control. A symposium on "Autogenous Grinding" will be held during the Congress. Further information can be obtained from Prof. M. G. Fleming, Royal School of Mines, South Kensington, London, S.W.7.

The first European colloquium on "Electron Probe X-ray Microanalysis", sponsored jointly by the Electron Microscopy and Analysis Group of the Institute of Physics and the Physical Society and the Sous-Commission Microsonde of France, will be held in Delft during September 14–15. The colloquium will be divided into three main sessions: instrumentation; quantitative microanalysis; applications of the electron probe microanalyser. Further information can be obtained from the Administration Assistant, the Institute of Physics and the Physical Society, 47 Belgrave Square, London, S.W.1.

SURFACE CONTAMINATION

UNDER the auspices of the American Association for Contamination Control, the Health Physics Society and the Oak Ridge National Laboratory, an international symposium on surface contamination was held at Gatlinburg, Tennessee, during June 8–12, 1964, and attracted about 170 scientists and engineers from nine countries.

Karl Z. Morgan (director of the Health Physics Division, Oak Ridge) opened the proceedings and described the type of accident which his department might have to deal with, according to the practical and fundamental knowledge at their disposal. Five years ago a small chemical explosion resulted in the dispersal of 600 mg of plutonium into the street, with more inside the building. They cleaned down to 30 disintegrations a minute and sealed over with paint. There was much curiosity about the physics and chemistry of the dispersal, attachment and removal of such contamination.

He then introduced A. M. Weinberg (director of the Oak Ridge National Laboratory) as a pioneer in reactor design and a dedicated research worker in the field of applying the vast and potentially cheap resources of nuclear energy to massive projects for the betterment of mankind. Dr. Weinberg spoke of the gas centrifuge, originally constructed for isotope separation but of limited value for this purpose, which was now being looked at by biologists as a potential separator of cell particles and viruses on a continuous scale. The discovery that *SM* 40 virus, a carcinogen in hamsters, had been present in live polio virus suggested the need of a purification process at the end of the production line; it was possible that the gas centrifuge might serve as a model.

The first of the four scientific sessions was opened by C. N. Davies (Medical Research Council and the London School of Hygiene and Tropical Medicine), who reviewed the deposition of aerosols from air in enclosed spaces. Gravitation, thermophoresis, photophoresis, diffusiophoresis and the electrical deposition of adventitious particles over a wide range of sizes were discussed and the respective rates of deposition were estimated. C. N. Segelstrom (Royco Instruments, Boston) gave an account of an electronic counter of airborne particles; light from a 2,850° K lamp, scattered at right angles by individual particles, is measured as a series of pulses which are claimed to be proportional to the square of the particle size, irrespective of its refractive index, complex or otherwise. In the discussion it was accepted that this claim was probably correct for sizes above 10μ, but the instrument was commonly used for smaller particles and a check was needed. The counter is well engineered and will operate, also, on liquid suspensions; it is widely used in hospitals and the electronics industry for monitoring airborne contamination.

A. A. Andersen (Provo, Utah) described a six-stage cascade aerosol sampler. Each stage consisted of a disk perforated with 400 holes which impinged on another disk, immediately below, made of aluminium or stainless steel. The flow rate was 1 ft.^{3}/min and the jet velocities ranged from 3·54 ft./sec for the first to 76·4 ft./sec for the sixth; the corresponding cut-off diameters for unit density spheres were 9·2μ–0·5μ. It was claimed that the use of multiple jets rendered adhesive films on the impaction plates unnecessary for many aerosols.

The investigation of surfaces was introduced by S. Ross (Rensselaer Polytechnic, Troy, New York), who described the effect of contaminating diatomaceous powders used in chromatography with 'Apiezon oil *B*', and tricresyl phosphate. The powders remained free-flowing, apparently dry and non-oily although carrying multi-layers of oil. Adsorption isotherms were obtained which were linear through the origin and the elution peak was symmetrical; the oil film evidently made the surface of the adsorbent more uniform. A single equation was derived for the isotherms produced with varying quantities of oil.

J. F. Pudvin (Bell Telephone Laboratories, Allentown, Pennsylvania) discussed methods of gauging the cleanness of metal surfaces in considerable detail. A new method involving cooling below the dew-point was described. Condensation patterns map the clean areas and the first formation of droplets indicates sites of hydrophylic activity. A neat method of measuring the contact angle had also been used. Gold was unusual among metals in always having a hydrophobic surface; on other metals the presence of oxide rendered the surface hydrophylic. These techniques provided a new standard for detecting contamination in the minutest traces.

An original way of measuring surface contamination had been developed by J. L. Anderson (Orlando, Florida). A film of decyl bromide containing 1–3 atoms of carbon-14 was applied to the surface in question and a thin end-window counting-tube was set close above it. Nitrogen was passed through the gap and, if the surface was clean, all the decyl bromide evaporated in 30–40 sec. Surface contamination slowed down the rate of evaporation and was characterized to some extent by the shape of the decay curve. The solvent used to apply the radiochemical absorbed the soft β-rays and was chosen, therefore, to be of much higher volatility.

The next session was opened by Morton Corn (University of Pittsburgh), whose subject was mechanisms of dust redispersion. The removal of particles from a surface was effected by centrifuging up to 250,000g and by blowing with a tangential air stream; the aerodynamic force on the particle was calculated from the velocity profile of the boundary layer. In the blowing method it was found that time was a factor; this did not apply to centrifuging. Mica particles always lie flat and though their adhesion was less than that of glass, in the centrifuge, it was not possible to blow them off.

L. A. Masironi and B. R. Fish had also constructed a small wind-tunnel with a 0·25-in. working section for the investigation of re-entrainment. Using stroboscopic lighting the behaviour of glass spheres 28μ in diameter had been observed in an air current of 5,000 cm/sec. 32 per cent of the spheres blew right away; 6·5 per cent rolled first and were then detached. 6·5 per cent rolled but stayed on the surface and 55 per cent failed to move. The rolling velocity was only 10^{-5} of the air speed. R. L. Walker and B. R. Fish described an apparatus for oscillating a surface in order to apply acceleration; no 30μ particles had been shaken off using maximal acceleration normal to the surface of 90g.

Three papers followed which dealt with the redispersion of particulate material from surfaces. K. Stewart defined the re-suspension factor, K, as the air concentration in μc. per m^3 divided by the ground concentration per m^2. No good correlation of K with air velocity, particle size or density was obtainable and values ranged from 10^{-4} to 10^{-8}. It was not usually found that deposits from accidental spills out of doors weathered away; on the contrary, the material might weather into the top few millimetres of surface, rain and dew aiding this process and consolidating the surface. The re-suspension factor, in general, was smaller out of doors than indoors because of this effect and the rough nature of outdoor surfaces in comparison with those indoors. The half-life of outdoor ground contamination was 40–100 days for 10μ particles and less for coarser ones.

At Harwell, I. S. Jones and S. Pond found that values of K as large as 5×10^{-5} were associated with vigorous walking and detected a consistent difference between plutonium oxide and plutonium nitrate. Autoradiography indicated that activity was present in particles from 0·4μ to 60μ diameter with the number median size 5μ and the activity median 14μ. The particle size distributions were similar on the floor and in the air. At Windscale, R. T. Brunskill had measured values of K as high as 8×10^{-3}, due to dust from clothing.

Experiments on redispersion of settled dust, by B. R. Fish *et al.* (Oak Ridge), indicated that a person was likely to inhale about one particle per hour, around 3μ in size, for every 4,000 per m² on the floor when working in a room contaminated with dust of copper oxide or zinc sulphide. The mass concentration decreased by a factor of only 2 in going from ankle level to the breathing zone.

The session which followed was devoted to aerodynamic transport and deposition. S. K. Friedlander (California Institute of Technology, Pasadena) had developed an ingenious new sampling device for aerosols of particles between 70 Å and 0·1μ in diameter. It consists of a 1-in. diameter disk rotating at 2,000 r.p.m. A spiral flow towards the surface of the disk is induced which has a component normal to the disk; the normal velocity is the same at all radii and depends only on the distance from the disk. The diffusion of fine particles from this flow, on to the disk, is uniform over the entire surface. An electron microscope slide was set in the disk and runs of 10–70 h enabled size distributions to be obtained of fine atmospheric particles.

The next paper was by C. N. Davies, who reviewed the various mechanisms of deposition from moving air streams and directed attention to complicating factors in gravitational and turbulent deposition.

A method of estimating ground contamination resulting from the destruction of an aerospace vehicle was suggested by E. M. Wilkins (Dallas), who treated it as an instantaneous point source expanding according to turbulence theory, but made no allowance for changing conditions as the ground was approached.

L. P. Davis (University of Tennessee) calculated the deposition of particles in ducts combining inertia deposition, due to turbulence, with Brownian motion; the analogy between heat and mass transfer was used for the latter and coagulation was allowed for. Similar velocities of deposition were obtained for 10μ and 0·01μ diameter particles (about 0·1 cm/sec) with a minimum velocity between 0·1 and 1μ.

The preceding scientific sessions were followed by technical sessions on control, measurement and decontamination, including papers on micro-organisms and chemicals.

There was considerable discussion about working limits for radioactivity. H. J. Dunster (Harwell) claimed that the intake by breathing was negligible, and air sampling was unnecessary, if the surface contamination was below the maximum permissible limit. Surface contamination was easy and cheap to measure. He suggested maximum permissible levels of 10^{-4} μc./cm² for control areas and 10^{-5} for inactive areas and skin; these figures correspond to 20,000 and 2,000 α-disintegrations/min.100 cm² or 6,700 disintegrations per min from the hands.

This view was contested by H. Blatz and M. Eisenbud (New York University), who also outlined some of the legal difficulties associated with standards. H. Glauberman and W. R. Bootman (U.S. Atomic Energy Commission, New York) presented data showing the wide range of air concentrations associated with a given surface contamination in handling uranium and plutonium, a factor of more than 100 being involved, in agreement with the wide range of values of the re-suspension factor, K, which had been quoted in papers presented during the scientific sessions.

The necessity of avoiding undue interference with operations was stressed by G. W. Spangler (University of California School of Medicine). Permissible contamination limits were derived by evaluating the external radiation hazard from surface contamination and the risk of body deposition from airborne material released from the surface. Here limits were much narrower than the International Commission on Radiological Protection air concentration figures and were based on surface contamination causing no more than 10 per cent of the permissible dose. Inhalation came out as equated to the absorption by a 40 cm² wound, which is a considerable area.

The view of the Commissariat à l'Energie Atomique, France, was presented by J. Hamard. Inhalation was regarded as the main hazard from surface contamination which is not bound. It was indicated that, for a 40-h week, 10^6 times the maximum permissible concentration for air in μc./cm³ gave conservative limits in μc./cm² for surface contamination. On this basis external β-radiation from the surface is taken care of.

Four papers followed on measurement techniques. The filter paper 'swipe' had been studied by J. R. Prince and C. H. Wang (Oregon State University). Part of the paper was cut out after rubbing the surface, moistened with phosphor and placed in a standard vial for scintillation counting. Millimicrocuries could be estimated with efficiencies up to 5 per cent or more for tritium and 50 per cent for carbon-14. A dry swipe was better than a wet one. 10^{-4} μc./m² gave some 40 counts/min.

J. E. Dummer (Los Alamos) had made an examination of use of portable radiation survey meters for surface β-emitting contamination. Large areas were simulated by dotting the outline with solution of strontium-90 + yttrium-90 in equilibrium. Sources up to 5-cm diam. were found to act as point emitters; large correction factors were needed for calculating surface dose rates from the meter readings.

R. Wilson and G. A. Vivian (Ontario Hydro-Electric Power Commission) also discussed the relationship between the detector indication and surface activity, considering geometrical factors.

Adhesive paper, smear and 'smair' techniques for assessing surface contamination were compared by G. V. Royster and B. R. Fish (Oak Ridge). The smair sampler contained a filter in a housing which was pressed on the surface. A series of peripheral jets, inclined at 45°, blew air at 90 m/sec or more on the surface inside the hood and released contamination which was trapped on the filter. Although the actual quantity of activity collected by this device was often less than that removed by other methods it gave very much more reproducible and realistic results. For example, equivalent contaminations of dry and on oiled concrete were returned as the same by the filter paper smear method, whereas the 'smair' sampler detected less from the oiled surface.

An instrument developed at the Illinois Institute of Technology was described by D. Werle. This was for estimating traces of non-volatile residue in rocket fuels which created an explosion risk when present as contamination on the internal surfaces of empty fuel tanks. A sample of the fuel was sprayed in drops smaller than 3μ, and after evaporation of the volatile bulk of each drop the residual aerosol was measured by 40° forward light scattering. The apparatus was calibrated with dilute solutions in 'Freon' or trichloroethylene.

W. J. Kerrigan (of Du Pont, Aiken, South Carolina) had prepared a series of standard dusts in sizes of 0·2μ–44μ by sieving and air elutriation. Ground uranium oxide and Alcoa aluminium were available and redispersed well after storage in bulk.

A. K. Baker (Chandler, Arizona) described air-flow problems in outflow hoods designed to protect delicate operations from contamination by room air. The formation of vortices downstream of objects in the working zone led to the entrainment of room air.

A neat new tool for changing the gloves in a glove box without opening up the box was described by J. B. Owen (Dow Chemical Co., Golden, Colorado). The change could be effected in less than 2 min.

The last two papers of this section, from North American Aviation and Grumman Aircraft, were devoted to the routine of controlling dust-free areas in factories. More than 70 per cent of missile failures are due to contamination; the high degree of reliability which is aimed at necessitates the use of 'clean-rooms' and the organization of appropriate training for the staff who build the complex miniaturized electronic navigational devices.

Regular observations of the dose rate from radioactive fall-out had been maintained by Th. Franke of Frankfurt, Germany, using a 4·5-in. sodium iodide crystal for γ-ray spectrometry. An increase from 1·5 microrads/h to 4·0 was observed during 1962–63. Snow cut the rate by 50 per cent.

E. D. Graham (Argonne National Laboratory) described the α-particle monitoring programme which was established when a reactor at Idaho Falls was switched to plutonium core loading. The routine included aerosol sampling, monitoring surface contamination and external radiation, evaluation of internal exposure of personnel and the dosimetry of external exposure.

The control of surface contamination at the Atomic Weapons Research Establishment, Aldermaston, was explained by W. N. Saxby and J. A. Hole. The general strategy was one of containment in limited areas where protective clothing was worn. Monitoring equipment was described and the derived working levels used in contamination control were summarized.

L. K. Burton (Berkeley Nuclear Laboratories) stated that a serious problem at nuclear power stations was the lack of a quick method of assessing the relative proportions of plutonium, uranium and natural α-emitters. In the presence of large masses of concrete the background of radon daughter products was high and confused the picture. Air sampling was to be performed with a small filter attached to the worker which, when combined with a solid-state radiation detector, would indicate large, active individual particles.

Five papers dealt with microbial contamination. T. W. Kethley (Georgia Institute of Technology) had carried out numerous experiments with bacterial aerosols which could be detected down to one particle, or 10^{-13} g/ft.^{3}. The mathematical calculation of concentration in ventilated rooms was explained for steady-state and transient conditions. In practical situations the equivalent settling diameter of bacterial particles was 10–20μ, due to their association with foreign matter.

K. R. Goddard (U.S. Public Health Service, Savannah, Georgia) had used various sampling methods in investigations of bacterial distribution in hospitals. Counts of airborne viable organisms of 40–50/ft.^{3} were regarded as high and at 150 conditions were bad. Investigations of surface coatings had shown epoxy paints and varnishes to be a good substitute for tile; they could be applied directly to concrete block walls, using the correct undercoat.

G. S. Michaelsen and D. Vesley (University of Minnesota) presented two papers. The first was based on work with the Casella slit sampler, supplemented by the Andersen sample for finding size distributions. Low bacterial counts were found to be associated with the pressure ventilation of operating rooms. The counts correlated with the movements of personnel and it was clearly desirable to avoid unnecessary movements. The peaks ranged from 5 to 20 particles/ft.^{3}. Local sources of bacteria included the chutes for soiled linen, which were efficient disseminators and transferred contamination from floor to floor. Work with selective media had been facilitated by a multi-point tool for inoculating plates. The prevalent organisms tended to differ from one hospital to another; the higher Gram-positive cocci were associated with people and the lower ones, rods and moulds with dust.

Their second paper was a statistical evaluation of 'Rodac' agar contact plates which, in addition to having some advantages over Petri dishes, when used in the ordinary way, could be pressed, without sliding, on a surface to record the surface contamination. An analysis of floor contamination in hospitals was made and the efficiency of floor disinfection methods was evaluated.

There is international agreement that space-vehicles landing on other planets must be sterile, and L. B. Hall (special assistant for planetary quarantine, National Aeronautics and Space Administration, Washington, D.C.) gave an account of the difficulty of implementing a guarantee of absolute sterility. He approached the subject historically, from the Mosaic laws pertaining to food. Experiments showed that the die-off of organisms on steel surfaces was complete in 48 h at 25° C and in 8 h at 50° C so long as the relative humidity was in the neighbourhood of 45 per cent. Higher or lower humidities favoured the retention of viability.

The Boeing Co., Seattle, was also concerned with the same problem, and Karl Kereluk, R. Meyer and A. J. Pilgrim went into the problem of constructing a highly complicated and completely sterile planetary lander. 'Rodac' plates were used in this work.

Two papers on beryllium followed. J. J. Cohen and R. N. Kusian (University of California) had found it difficult to correlate surface contamination with health hazard on account of the many factors governing redispersion. R. N. Mitchell and B. C. Eutsler (Los Alamos) examined the air and surface contamination in a beryllium store. Small cyclones, operating at 2 ft.^{3}/min. and May pre-impingers passed, respectively, 6 and 10 per cent of the airborne material, indicating that most of the beryllium was in coarse dust. Floor contamination ranged from 860 to 1,860 μg/ft. and the air concentrations, during resuspension tests, were between 2·9 and 25·8 μg beryllium/ft.^{3}.

A session on insurance and economics was opened by R. G. McAllister (Liberty Mutual Insurance Co., Hopkinton, Mass.). A major release of fission products had been regarded as a risk which involved a potential liability of such magnitude that two pools, involving more than 250 private companies, had been formed to deal with this business. The Price–Anderson amendment of 1951 extended the cover to 500 million dollars for any one nuclear incident. Exclusion clauses in domestic and automobile policies were explained; these were intended to prevent duplication of coverage. The total cost of an incident was linked with the stringency of standards for residual contamination in public places and safe, but realistic, limits were necessary.

R. G. Gallagher (Pittsburgh) gave an interesting account of a number of incidents in which radium, for medical use, had become disseminated by breakage of containers. P. Loysen (U.S. Atomic Energy Commission, New York) described six episodes where decontamination of buildings had been undertaken. The cost ranged from 0·11 to 2·54 dollars per square foot. Here, again, the specification of realistic levels for residual contamination was a vital economic factor.

The symposium was terminated with three papers on decontamination from France, Japan and England. P. Cerre and E. Mestre (Saclay) gave an account of a 500-kg furnace which was used for melting lead. The contamination was held in a slag of the oxides of aluminium, silica and calcium at the surface and was separated when the lead was run off into ingot moulds. An output of 2 tons a day was possible. Acetic acid and hydrogen peroxide were used for cleaning surfaces. An electrolytic polishing process had also been developed.

Y. Nishiwaki spoke of the theory of decontamination, and the use of EDTA and DBS. They had experienced highly active rainfall in 1961, from Russian tests, which contained giant particles of 0·1–1 μc. each. Instruction had been issued for fruit and vegetables to be washed and bread containing activated charcoal had been issued.

G. W. Clare gave a short history of the development of the decontamination service at Harwell. The building and plant, now in use, had paid for itself in only two years when costed on equipment which had been saved and put back into service. They moved everything by overhead tackle, which was much more satisfactory than trucking, and grid floors, with all services below, had been very successful. The centre is adjacent to the Active Waste Disposal Building and carries its own trained staff.

C. N. DAVIES

STRUCTURE AND FUNCTION OF LIPID-CONTAINING SYSTEMS

A JOINT meeting of the British Biophysical Society and the Biochemical Society attracted more than 200 participants to the University of Birmingham during April 20–21. A comprehensive survey of research relating to lipids and cell membranes was undertaken in three sessions devoted to physical chemistry of lipid systems, composition and molecular structure of cell membranes, and the role of lipid in membrane activity.

An introductory talk by Dr. D. G. Dervichian on the general theme of the symposium was followed by 20 papers.

Information derived from X-ray diffraction (V. Luzzati) and infra-red spectroscopy (D. Chapman) served to emphasize the liquid crystalline nature of lipid layers under a variety of conditions and the complexity of phase relationships in mixed lipid systems. D. Attwood and L. Saunders, and D. B. Gammack, discussed the characteristics of dispersions of lipid in water as examined by light-scattering techniques, and A. D. Bangham and D. A. Haydon the interpretation of birefringence measurements. J. A Lucy and M. Glauert presented a molecular interpretation of their electron micrographs of negatively stained lipid preparations and discussed its possible significance in relation to cell membrane structure.

A review by G. M. Gray of data on the compositions of a variety of cell membranes was followed by a report on the lipid components of membranous fractions from brain homogenates by J. Eichberg and R. M. C. Dawson. B. R. Malcolm presented evidence for the α-helical configuration in protein layers at air–water interfaces and A. A. Eddy and P. Johns speculated about the possible arrangements of lipoprotein sub-units in the red cell membrane. J. B. Finean summarized present views on the molecular structure of cell membranes and N. R. Silvester discussed the analysis of the remarkably detailed X-ray diffraction patterns obtained from membrane material derived from cilia. P. F. Millington spoke of the various factors which influenced the widths and densities of lines which characterize cell membranes in electron micrographs, and R. Dourmashkin discussed correlations between the number of sites of interaction of immune complexes with the surface of the red cell as seen in electron micrographs and the rate of lysis of the cells.

In the final session, J. N. Hawthorne undertook an assessment of present ideas on the role of individual phospholipid components in ion transport and A. D. Bangham and J. C. Watkins suggested that their observations on the accumulation of ions inside lipid micelles might have some relevance to this problem. G. Hübscher discussed the problems associated with the assessment of the influence of lipid components on the activities of enzyme systems and A. Martinosi presented biochemical and electron microscope data relating to the inactivation and reactivation of muscle microsomes by removal and restoration of the lecithin components. L. L. M. van Deenen summarized a variety of data relating to the metabolism of phospholipid fatty acids in cell membranes.

J. B. FINEAN

RESEARCH EXPENDITURE AND INDUSTRY

IN his presidential address to the twentieth annual general meeting of the Institution of Metallurgists on May 13, Dr. L. Rotherham dealt with the interrelationship of the growth of numbers of qualified scientists and technologists, the national economy as a whole, productivity and the proper expenditure on research and development. As such, his address was a noteworthy contribution. Although obviously directed to the metallurgist in the first place, it is worthy of close study by all concerned with the more general problems.

The new industries, such as electronics and man-made fibres, have achieved commercial success by exploiting scientific and technological advances and in the process have ploughed back large sums for increasingly expensive researches. Thus during a period of time they have been able to produce and sell a succession of products. In contrast, some of the older industries have been relatively slow to adopt new techniques though the pace will probably quicken in the next few years. The danger is that they will not put aside the money required to develop ever-better processes and products. In 1962 industry employed some 9 qualified men per £1 million of 'gross domestic product' outside the research and development departments. In 1956 it had been 7·9, and on the basis of a 4 per cent economic growth and what appears to be a reasonably steady figure of 10·5 qualified men per £1 million of 'gross domestic product', an additional 100,000 scientists and technologists may expect to find employment in industry between 1962 and 1970. If all employers, even the smaller, were to raise the number of 'qualified men' (that is, those with degrees, diplomas and those who take the examinations of professional institutions) employed to that of the highest percentage, almost half as many more would be needed. This increased number of scientists and technologists is seen by Dr. Rotherham as being increasingly provided by university graduates.

In 1961–62 about one-fifth of Britain's total qualified men were engaged on research and development, and if this ratio remains constant, between 1962 and 1970, about 25,000 extra people will be required. The annual cost, on the average, is of the order of £11,000 per man engaged in such work, and for this increase a rise in productivity of some 3·8 per cent would suffice. The calculation, however, depends on the assumptions that research expenditure remains at the 1961–62 level of 2·7 per cent of the 'gross domestic product' and that research costs per man do not increase by more than 3 per cent per annum. In Dr. Rotherham's opinion, it might be prudent at this time to raise the percentage of the 'gross domestic product' devoted to research in order to counterbalance any shortfall in productivity, say, to 3 per cent (the American figure is already more than this). After making the usual allowances for rising costs, this should provide for an extra 6,000 research workers per annum. The

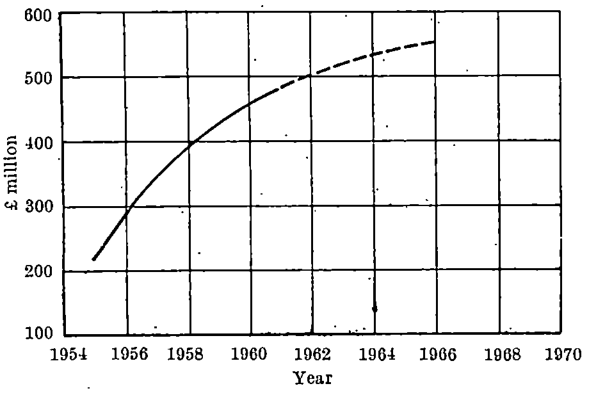

Fig. 1. Total British research expenditure (adjusted to take account of the fall in the value of the £)

wisdom of this is further demonstrated by the graph of total expenditure on research and development, since 1955, which, as can be seen from Fig. 1, seems to be levelling off at £550 million per annum, and also this expenditure expressed as a percentage of the 'gross domestic product' where the graph suggests a levelling around 2·8 per cent (Fig. 2).

In the second half of his address, Dr. Rotherham was concerned with the prospects for metallurgists in the future and the part to be played by the professional institutions. The enhanced status of metallurgy, in which the universities have played a major part, is indicated by the fact that in 1962, despite the recession, only six men who graduated that year in the subject were known to be still looking for jobs six months later. The immediate outlook is for about a 9 per cent increase per annum in the demand, even apart from increased employment in institutions of higher education and the special research expansion called for in the iron and steel industries.

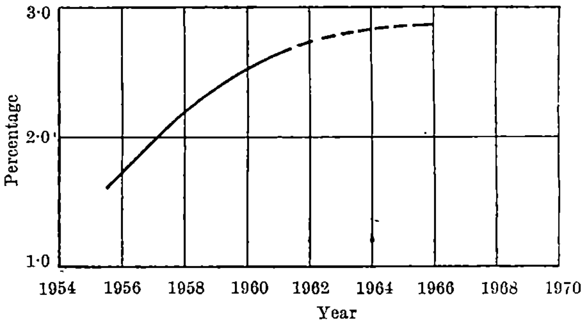

Fig. 2. Research expenditure as a percentage of the 'gross domestic product'

A pressing need is seen by Dr. Rotherham in effecting a better and more realistic image of the applied sciences to school children, their teachers and parents, and the public generally. In this the professional institutions can play a major part, especially since their function, with the increase of university graduates, will become less and less concerned with their own examinations.

It is concluded, therefore, that the numbers of men qualifying in science and engineering are increasing and will continue to increase within the foreseeable future. Membership of professional institutions is showing a corresponding growth. The full employment of these men is governed by industrial expansion and modernization, or putting it another way, commercially successful industries will need more qualified men to design, install and manage new plant. These industries will also provide the money, either directly or from taxes paid to the Exchequer, for increasingly expensive research and technological development. In contrast, any falling off in productivity will lead to a slowing up of plant modernization and research effort. Present indications are that industry will want all the qualified men it can get.

F. C. Thompson

FUNCTION OF AN INDUSTRIAL RESEARCH LABORATORY

THE above title poses questions which will always be controversial between scientists whether 'pure' or applied—since there are no precise answers. The points at issue will always hinge round the query whether an industrial laboratory should rightly embark on problems of academic interest, and vice versa. Can these two extremes be combined without detriment to both ? The principal arguments are familiar. On one hand is the alleged ivory-tower complex of the academic scientist, isolating him from the practical realities of what he is investigating. On the other hand is the severely practical approach of the technologist, who is not allowed time or opportunity to wander into the by-ways of his subject, thereby perhaps missing new vistas which could lead to important discoveries. The giant industrial companies can, of course, afford to set up as independent establishments laboratories for fundamental research akin to those of the universities. At the other end of the scale the small company can afford to cater only for its day-to-day problems, and these inevitably are purely practical.

The problem therefore becomes of real significance with companies somewhere between these two extremes, and there are many in this category. The opening of New Butler's Court, Beaconsfield, Bucks, the Research Centre of the Wiggins Teape Group of papermakers, on March 20, 1963, following a visit of inspection by the Duke of Edinburgh on the previous day, directs attention to a particular case of this kind. Butler's Court, as purchased by the Company in 1956 on the site of Edmund Burke's former home, provided 13,500 ft.^{2} of laboratory space. Since then a further 19,000 ft.^{2} of laboratories and pilot plant buildings have been erected, and the above occasion was the inauguration of these by the chairman, Mr. L. Farrow.

Wiggins Teape are papermakers and paper converters operating, in the United Kingdom alone, 15 actual paper mills and 15 factories where associated manufactures are carried on. Although the general research requirements of the paper industry are handled by the British Paper and Board Industry Research Association which the Wiggins Teape Group supports, the Company has perhaps more specialized problems than any other of its kind, since it manufactures speciality papers and in particular the so-called 'industrial papers'. Examples are: papers for impregnation with plastics, photographic base papers, leather papers, photo-copying and other copying papers, and chart papers resistant to water and oil. These, of course, are in addition to the usual types of high-grade writings and printings, and speciality wrappings such as vegetable parchment and glassine.

With a wide and varied production of this nature the interface between pure and applied science becomes increasingly diffuse. However, Dr. H. F. Rance, technical director, recently summed up the policy of his company quite unambiguously by pointing out that research and development are regarded as a business activity which must show returns commensurate with expenditure. Since they exist to promote change, in the interest of the

Company, they must themselves be flexible and adaptable. For this reason Butler's Court has been built, item by item, to meet specific needs.

Such a policy does not of necessity exclude fundamental research. Thus a basic approach has been made to the investigation of the structure of paper with special reference to the statistical geometry of the arrangement of fibres in a sheet. This has enabled the arrangement of the fibres during the formation of the sheet to be predicted mathematically, and thence it should be possible to predict also many of the physical properties of the finished paper. Such work has a natural practical sequel in the possibility of designing papers with special properties, and in the subsequent mill control necessary to ensure that these properties are achieved continuously in practice. Hence the existence of a printing room and a pilot plant aqueous coater, solvent coater and an extrusion laminator which, together with the papermaking pilot plant area, workshop and electricity substation, cost £235,500 for building and equipment. The coating plant is a special feature, since it can run at 3,000 ft. per min and can be operated with air knife or blade coater methods.

Finally, the implementation of all this development work involves an effective system of mill control to ensure that the papers are manufactured to the correct standard of quality, and, of course, profitably. Quality control in the form of factory instrumentation, the development and application of testing instruments, and a system of routine testing, is a major activity directed from Butler's Court.

This, briefly, is one Company's general conception of the function of an industrial research laboratory. The recent opening of the extension to Butler's Court is at once full justification for the initial step taken in 1956, and a tribute to the direction of the laboratory in the intervening period.

Julius Grant

POTASSIUM–ARGON AGES OF SLATES AND THEIR GEOLOGICAL SIGNIFICANCE

By C. T. HARPER

Department of Geology and Mineralogy, University Museum, Oxford

A PROGRAMME of potassium–argon dating is being undertaken at Oxford on material from the British Caledonides, and during the course of this work the possibility of using whole-rock samples of slate for age determination was investigated. A few whole-rock slate ages have appeared in the literature[1–4] and recent work[5] has demonstrated the possibilities of using slates on a regional basis to date an orogenic (Hercynian) belt. In the Grampian Highlands of Scotland, a wide range of metamorphic grade allows whole-rock potassium–argon ages of slates to be compared with ages of muscovite and biotite from schists belonging to the same (Caledonian) metamorphic complex.

The metamorphic rocks south of the Great Glen consist of two major units, the Central Highland Granulites, similar to the Moine Series to the north, and the Dalradian Series. The Dalradian Series is divided into two structural and stratigraphic groups, the Ballapel Foundation and the Iltay Nappe Complex, each characterized by a distinct stratigraphic succession. The succession in the Iltay Nappe Complex can be divided into Upper, Middle and Lower Dalradian[6,7]. Slates and schists were collected for age determination from the Upper and Middle Dalradian of the Iltay Nappe, and from the Ballapel Foundation. Schists were also collected from the Central Highland Granulites.

The Dalradian slates are characterized by fine-grained muscovite–chlorite–quartz assemblages, the amount of muscovite relative to chlorite and quartz being directly proportional to the K_2O content of the rock. Although it was not possible to separate micas from any of the slates, X-ray diffraction analysis confirms the presence of muscovite, and shows that in all cases it possesses a high degree of crystallinity. Basal (001) muscovite peaks show no tendency to asymmetry, and the overall diffraction pattern is indistinguishable from that of completely recrystallized muscovite in the schists. Paragonite–muscovite–chlorite–quartz assemblages have been found in three slates[8]. The Middle Dalradian slates collected from the Iltay Nappe Complex have a characteristically strong strain-slip cleavage superimposed on the main slaty (flow) cleavage, while Upper Dalradian slates from the Nappe Complex commonly show little or no strain-slip cleavage. Strain-slip cleavage is particularly strong in slates collected from the Ballapel Foundation, and in some cases becomes the main cleavage in these rocks.

All samples for age determination were crushed and sieved to −40 +80 mesh. Muscovite and/or biotite in the schists were separated by conventional methods. The −40 +80 mesh fraction obtained from the slates was used for analysis without further treatment, the −80 mesh fraction being discarded owing to the possibility of argon loss from this finely ground material. Potassium was determined by flame photometer; argon was measured on a Reynolds-type, bakeable, mass spectrometer by isotope dilution with enriched argon-38; ages were calculated using the following constants:

Isotope abundance: $^{40}K = 0{\cdot}0119$ atomic per cent
Decay constants: $\lambda\beta = 4{\cdot}72 \times 10^{-10}$ yr.$^{-1}$
$\lambda e = 0{\cdot}584 \times 10^{-10}$ yr.$^{-1}$

The calculated ages are summarized in Fig. 1. Each point represents the potassium–argon age at one locality. Samples are divided into 4 classes, and the isotope ages of the samples in each class are arranged in numerical order and plotted in cumulative frequency. The mean age and standard deviation ($2\bar{\sigma}$) for each class is as follows:

Mica	
(1) Muscovites (from Central Highland Granulite and Dalradian mica schists)	436 ± 9 m.y.
(2) Biotites (from Central Highland Granulite and Dalradian mica schists)	424 ± 6 m.y.
Whole rock	
(3) Slates (from Middle Dalradian and Ballapel Foundation)	431 ± 6 m.y.
(4) Slates (from Upper Dalradian)	461 ± 8 m.y.

The mean ages of muscovites, biotites and Middle Dalradian and Ballapel Foundation slates are equal within the limits of error, and taken together give a weighted mean of 429 ± 4 m.y. (compare averages obtained from Moine schists[9–11]). The mean age for the Upper Dalradian slates is significantly higher.

The observed similarity between Middle Dalradian and Ballapel Foundation slate and mica ages suggests that preferential loss of argon from the slates has not occurred and that whole-rock potassium–argon ages obtained from slates are equivalent to those obtained from metamorphic micas. Ages obtained from the Upper Dalradian slates, however, fall outside the range shown by the other slates and the micas, with two exceptions (Fig. 1). A Macduff slate from the north-east Dalradian, the only dated Upper Dalradian slate which does not come either from the

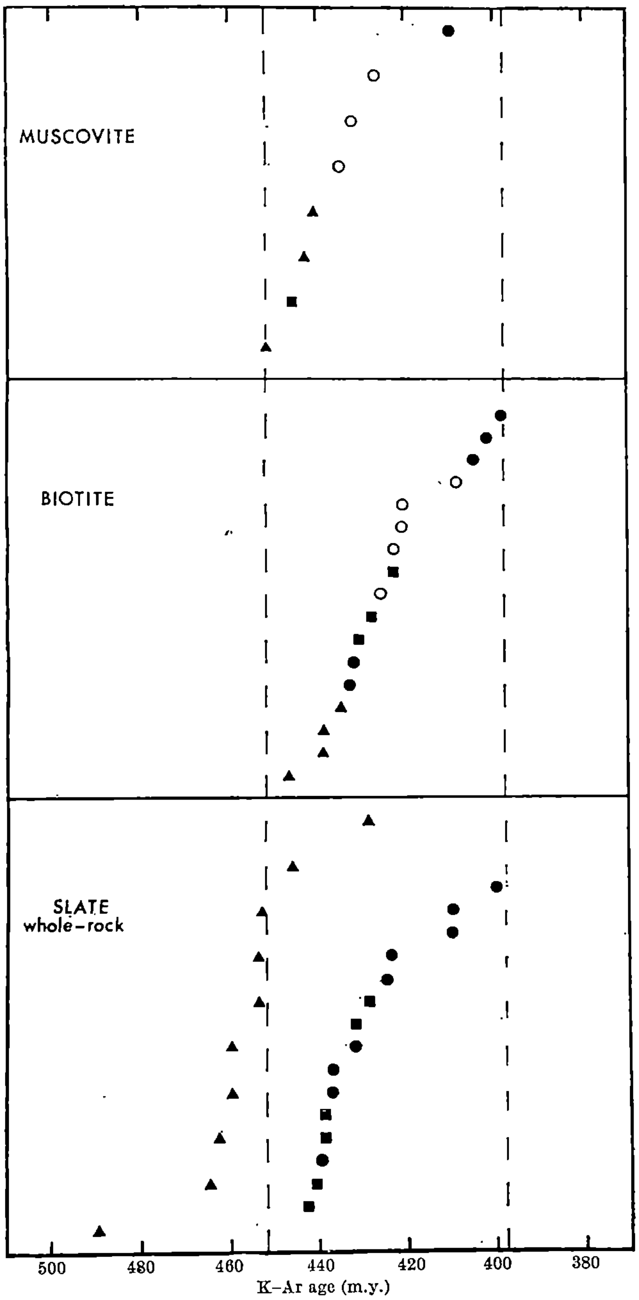

Fig. 1. Potassium–argon ages from the Dalradian Series and Central Highland Granulites
▲, Upper Dalradian; ●, Ballapel Foundation; ■, Middle Dalradian; ○, Central Highland Granulite

Loch Awe Syncline or Aberfoyle Anticline (synform) in the south-west, gives an isotopic age of 429 m.y., 32 m.y. less than the average age for the Upper Dalradian slates, and a Tayvallich slate from the Loch Awe Syncline, which has an exceptionally strong strain-slip cleavage in comparison with other Upper Dalradian slates, gives an age of 446 m.y., 15 m.y. less than the Upper Dalradian average.

Two possible sources of error in the whole-rock slate ages must be considered[12]: (1) the presence of pre-metamorphic argon in detrital minerals which have survived metamorphism; (2) loss of argon during subsequent post-metamorphic history. Although these affect the isotope age in opposite directions, it is most unlikely that both factors are so balanced at each locality in the Dalradian as to give whole-rock slate ages in close agreement with mica ages from schists belonging to the same series. Furthermore, experimental work[13] has shown that loss of argon is facilitated during lattice disturbances of any kind and particularly during loss of water. Such conditions are likely to arise during the formation of slaty cleavage in pelites[14], and result in loss of argon from their detrital constituents.

Although the presence of detrital minerals containing pre-metamorphic argon in the Upper Dalradian slates might account for their higher ages, there is no positive evidence for the presence of such minerals in these slates. Recrystallization and slaty cleavage are as fully developed in these as in slates giving lower ages. Bearing in mind the distinct stratigraphic and tectonic position of the Upper Dalradian slates, their higher potassium–argon ages most probably have a geological, rather than mineralogical, significance.

Experimental and geological evidence[15] suggests that radiogenic argon will not accumulate in the crystal lattices of potassium-bearing minerals above temperatures in the range 100°–200° C. This is below the range where greenschist facies metamorphism is believed to occur[16], and implies that potassium–argon ages of minerals from schists reflect a time of cooling, rather than metamorphism. Isotope ages conforming to such a cooling history have been reported from the Himalayas[17] and European Alps[18], where metamorphic minerals from upper tectonic units give older ages than minerals from lower units which would have cooled more slowly. In the Dalradian Series and the Central Highland Granulites, consistent potassium–argon age differences are found between coexisting muscovite and biotite, irrespective of their relative order of crystallization in the rock, indicating that argon began to accumulate in muscovite some 12 m.y. before it began to accumulate in biotite. In terms of a cooling history, this suggests that argon can accumulate in muscovite at somewhat higher temperatures than it can in biotite.

Cooling of a metamorphic belt is most likely to occur as a result of uplift. Evidence from the New Zealand Mesozoic metamorphic belt[15] shows that argon did not begin to accumulate in the constituent minerals of deep-seated metamorphic rocks until post-metamorphic uplift along the Alpine Fault in Late Tertiary times brought these rocks near the surface. In Scotland, post-metamorphic uplift and cooling of the Dalradian block is likely to have occurred immediately prior to denudation. Severe denudation of the Dalradian undoubtedly occurred at the close of the Silurian with the deposition of Old Red Sandstone conglomerates. However, recent work in the Southern Uplands[19] has revealed the presence of Dalradian schist fragments in Wenlock sediments, suggesting that denudation of the Dalradian was already occurring in Mid-Silurian times. Uplift and cooling would therefore appear to have commenced during the Early Silurian, that is, about 425 m.y. ago using Kulp's time-scale[20]. This stratigraphic estimate for the time of cooling fits well with the average isotopic age of 429 ± 4 m.y. obtained from the Middle Dalradian of the Iltay Nappe Complex, the Ballapel Foundation, and the Central Highland Granulites.

Potassium–argon ages approaching the true age of metamorphism can only be obtained from materials which recrystallized during metamorphism under conditions resulting in complete outgassing of inherent argon, but at temperatures close to that at which subsequent radiogenic argon could accumulate. It is possible that recrystallization resulting in the formation of slaty cleavage occurs at such temperatures, and that high (stratigraphic) level slates which have cooled rapidly after metamorphism may yield whole-rock potassium–argon ages approximating to the age of metamorphism. In the Dalradian, the only high-level slates that have survived denudation are found preserved in the axis of the Loch Awe Syncline and downfolded nose of the Iltay Nappe (Aberfoyle Anticline). The older ages obtained from these Upper Dalradian slates, ranging upwards to 490 m.y., may therefore approach the true age of Dalradian metamorphism, which, from the stratigraphic relationships in Ireland[21], would appear to be pre-Arenig.

I wish to acknowledge the opportunity for research provided by a Shirtcliffe fellowship from the New Zealand University Grants Committee, together with advice from members of the Oxford Geological Age and Isotope Research Group.

CONCENTRATIONS OF CÆSIUM-137, RHODIUM-102 AND MANGANESE-54 IN SURFACE AIR

By P. F. GUSTAFSON, S. E. MUNIAK and S. S. BRAR

Division of Biological and Medical Research, Argonne National Laboratory, Argonne, Illinois

THE concentration of various γ-emitting fission products present in surface air have been determined at this and other laboratories for a number of years[1-3]. Such measurements indicate the amount and composition of atmospheric contamination, and may also provide information regarding the age and even the source of fission debris[4].

At this laboratory airborne particulates were collected on '*H V*-70' filter paper (Hollingsworth–Vose asbestos base filter paper having an efficiency of ~96 per cent for particles of a diameter > 0·25μ) exposed on air pumps operated at flow rates of ~40 m³/h. A number of such pumps have been in continuous operation since late 1952. Known portions of each filter paper were combined to form monthly or semi-monthly composites containing particulates from ~10⁴ m³ of air. Physically the composites formed a compressed disk of finely cut filter paper enclosed in a plastic Petri dish, which was placed on top of a 4 in. diameter by 4 in. thick cylindrical NaI crystal for γ-ray spectrometric analysis. The crystal and source were contained in a 6-in. thick steel shield to provide a low background counting rate, and a 400 channel transistorized multichannel analyser was used for pulse height analysis. The quantities of the individual radionuclides present in the filters were determined by the solution of the appropriate number of simultaneous equations, the coefficients of which were found from the use of standard sources similar in shape to the composites and similarly placed on top of the crystal. During periods when fresh or reasonably fresh fission debris was present, the concentrations of the following radionuclides were determined by the foregoing method: ^{144}Ce–^{144}Pr, ^{141}Ce, ^{125}Sb, ^{103}Ru, ^{106}Ru–^{106}Rh, ^{137}Cs, ^{95}Zr–^{95}Nb, and ^{140}Ba–^{140}La. During the test moratorium as the amounts of the shorter-lived fission products decayed below detectable limits their analyses were discontinued, and analysis of ^{7}Be, produced by cosmic ray interactions in the atmosphere, was added to the computer programme.

Repeated analyses of filters collected during the spring months of 1962, several months after collection, indicated that another radionuclide or radionuclides were also present. Careful examination of a number of spectra in conjunction with estimates of radioactive half-life led us to conclude that ^{54}Mn and ^{124}Sb were present in surface air at that time. Hence, these two activation products formed during the 1961 Soviet tests were also considered in the mathematical analysis.

The concentration of ^{137}Cs observed in surface air a this site during January 1959–December 1963 is plotted in Fig. 1. As noted in the past, the most obvious feature is that of pronounced periods of maximum concentration during the spring months followed by periods of minimal activity during the autumn and winter. These maxima are believed to arise from increased stratospheric mixing during the winter and increased stratosphere–troposphere transfer during the spring months[5,6]. Similar phenomena have been observed in the case of ozone as reported and discussed by Brewer[7] and Dobson[8]. Prior to the resumption of nuclear testing in 1961, the highest concentration of ^{137}Cs in surface air, 0·035 pc./m³, was observed in 1959. Higher levels were present in 1962, ~0·08 pc./m³, and 1963, ~0·16 pc /m³, a fact which is not surprising in view of the large amount of fission debris injected into the atmosphere during 1961 and 1962. Another, less obvious, feature is that the peak concentration occurred later in 1961, 1962 and 1963 than in previous years. With the exception of 1953, when the ^{137}Cs concentration was so low that it might easily have

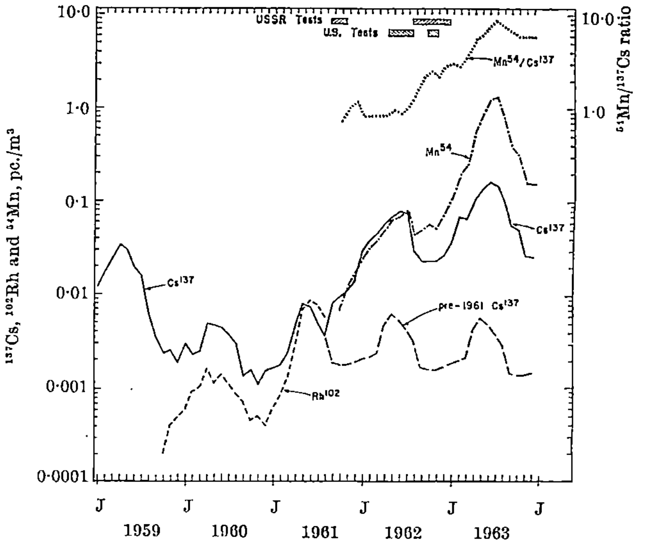

Fig. 1. ^{137}Cs (——), ^{102}Rh (– – –), ^{54}Mn (—·—·—) and ^{54}Mn/^{137}Cs (. . .) ratio in surface air

been perturbed by testing then in progress, the peak has been reached during April and May each year since measurements were begun here in late 1952. In 1961 the peak came in May and June, and in 1962 and 1963 the peak was not attained until June and July.

The delay in the appearance of the peak concentration during the past three years may be entirely fortuitous, or it may reflect some vagaries of the meteorological processes involved. There is evidence, however, that a fairly sizeable fraction of the total ^{137}Cs found in surface air during 1961–63 derived from events in which the nuclear debris was initially present at high altitude.

The presence of debris of high-altitude origin was determined by measuring ^{102}Rh and ^{54}Mn in surface air. The concentration of ^{102}Rh (corrected for radioactive decay to mid-August 1958) and of ^{54}Mn (corrected to mid-October 1961) are also illustrated in Fig. 1. Both radionuclides were activation products associated with high-altitude or high-yield explosions. ^{102}Rh was produced as a tracer in the Orange shot of the U.S. *Hardtack* test series on August 11, 1958, which had a burst height of about 43 km over Johnston Island (16° N., 170° W.)[9]. The highest concentrations of ^{102}Rh were reported by Kalkstein[9] to have been present in middle and polar latitudes in both hemispheres above 19 km from mid-1960 until late 1961. Hence the regions whence ^{102}Rh might enter into the lower atmosphere would similarly be situated in middle and polar latitudes. ^{54}Mn was produced in high-yield shots during the U.S.S.R. 1961 test series, debris from which must have risen well into the polar stratosphere, and its major source may be presumed to have remained there for some time. A second tracer, ^{124}Sb, was produced by activation in the 57-MT shot of this series. Unfortunately, the short half-life (60 days) has precluded to a large degree the investigation of this nuclide in surface air. However, investigation of ^{124}Sb relative to ^{54}Mn in high-altitude samplings have proven useful in ascertaining that no appreciable new input of ^{54}Mn occurred since 1961. ^{124}Sb and ^{54}Mn data obtained at 65,000 ft. from the *Ash Can* balloon flights made from San Angelo, Texas, indicate a fairly constant ^{54}Mn/^{124}Sb ratio from early 1962 until November 1963 (refs. 10, 11). This fact seems to imply that no significant amounts of ^{54}Mn were made subsequent to 1961. Other data from these flights show more ^{124}Sb relative to ^{54}Mn at higher altitude (80,000–100,000 ft.)[10], which is taken to mean that some ^{54}Mn may have been produced in explosions which led to the initial injection of debris to lower altitude than that from the 57-MT shot. In the spring of 1962 the ^{54}Mn/^{137}Cs activity ratio observed at 65,000 ft. had a mean value of 40 : 1 (ref. 10).

As indicated in Fig. 1, the peak concentration of ^{102}Rh in 1961 occurred in June and July. Similarly the concentration of ^{54}Mn reached peak values in June and July in both 1962 and 1963. The amount of ^{137}Cs and ^{102}Rh produced in the Orange shot is not known, although a figure of 3 megacuries of ^{102}Rh has been reported by Kalkstein[9]. One may presume that ^{137}Cs from other events, such as the Teak shot which also occurred at high altitude within days of Orange, have become mixed with that from Orange. In fact, aircraft sampling at 50,000 ft. during May 1961 indicated a ^{137}Cs/^{102}Rh activity ratio of nearly unity[12]. Such a value for this ratio would imply that all, or nearly all, of the ^{137}Cs shown in Fig. 1 during 1961 came from high altitude. If a smaller value of the ratio is used for debris in surface air, then the effect of removing the high altitude portion is that the maximum concentration shifts back to April and May 1961.

Likewise it is difficult to determine directly the amount of ^{137}Cs produced along with the ^{54}Mn, and the value of 40 : 1 for the ^{54}Mn/^{137}Cs ratio has been used. The observed values of the ^{54}Mn/total ^{137}Cs ratio are shown in Fig. 1. They indicate a fairly constant value during early 1962, followed by a steady increase during the latter half of 1962–mid-1963, at which time a new steady value is reached. This increase is somewhat surprising in view of the fact that considerable ^{137}Cs was produced during the summer and autumn of 1962. In order to examine the relationship between ^{54}Mn and ^{137}Cs produced in 1961 during subsequent years, it is necessary to determine the sources of the ^{137}Cs present in surface air.

Further examination of ^{137}Cs and other radionuclides produced during 1961 was attempted during 1962 and 1963 through the use of activity ratios; namely, ^{95}Zr/^{137}Cs, ^{103}Ru/^{95}Zr, ^{103}Ru/^{137}Cs, and ^{140}Ba/^{95}Zr. In addition, certain mean times of production were selected for the various test series: October 15, 1961, for the U.S.S.R. 1961 series; June 15, 1962, for the U.S. *Dominic* series; and October 15, 1962, for the U.S.S.R. 1962 series[13]. At the outset it was necessary to remove the ^{137}Cs which was produced in tests conducted prior to September 1961. For the period September–December 1961 the average ^{137}Cs values found in the same months during 1960 were adjusted by the ratio of the 1961–60 spring maxima. In 1962, the monthly averages of 1960 and 1961 observations were taken to be representative of the pre-1961 ^{137}Cs, and during 1963 these same values were reduced by a factor of 0·9 to account for radioactive decay and loss from the stratospheric reservoir. The pre-1961 ^{137}Cs values obtained in this manner are illustrated in Fig. 1. Removal of the pre-1961 ^{137}Cs from the total during early 1962 had the effect that on extrapolating back to a ^{95}Zr/^{137}Cs ratio of 145, the apparent time of origin was mid-October 1961, in accord with the assumed time of production for the series as a whole, and also in agreement with the findings of other investigators[14].

During June and July 1962 a new input of fission products was apparent from the abrupt rise in the ^{140}Ba/^{95}Zr and ^{140}Ba/^{103}Ru ratios. Estimates of the amount of ^{137}Cs associated with this new injection, which presumably came from the continental and Pacific phases of the U.S. *Dominic* series, were made through the use of the above ratios. The amount of ^{137}Cs ascribed to this series by these measurements was fairly uncertain. Suffice it to say that it was of the same order as that observed during comparable months during 1958 which arose from the U.S. *Hardtack* series as inferred from ^{181}W measurements made at that time[3]. Thus it has been assumed that the ^{137}Cs present during 1963 from *Dominic* was comparable to that observed in 1959 from the *Hardtack* series. From late August 1962 until the end of the year an appreciable amount of new debris became evident, the age of which varied between August to mid-December, the bulk of which was presumed to come from the Soviet tests then in progress[12].

During 1963, ^{137}Cs from pre-1961 sources and from *Dominic* was removed from the total. Similarly, the ^{95}Zr from *Dominic* was subtracted from the totals observed. The best fit to the ^{95}Zr/^{137}Cs ratio for the remaining ^{137}Cs and ^{95}Zr was obtained by using a mean time of production of October 15, 1962, for the interval January-July 1962, and a mean time of production of November 15, 1962, for the remainder of 1963. In the fitting process the excess ^{137}Cs was found, which excess was presumed to have arisen from the U.S.S.R. 1961 tests.

The results of partitioning the total ^{137}Cs, minus the pre-1961 component, into that attributable to *Dominic*, and the U.S.S.R. 1961 and 1962 series, are shown in Fig. 2. During the spring of 1962 less than 10 per cent of the total ^{137}Cs present in surface air collected at this location derived from tests conducted prior to 1961. In 1963, the pre-1961 component fell to less than 5 per cent of the total; approximately 70 per cent of the total came from testing in 1962, and the remaining 25–30 per cent arose from testing in 1961. The situation in 1963 was similar to that in 1959 when some 80 per cent of the total ^{137}Cs came from testing conducted the previous year[3].

The ratio of ^{54}Mn relative to the ^{137}Cs from testing in 1961 is shown in Fig. 3. The variation of the ratio with time is essentially the same as seen in Fig. 1 except that

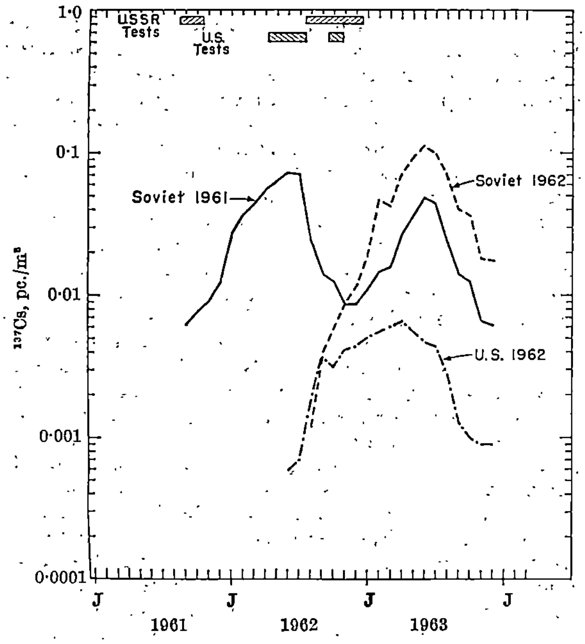

Fig. 2. Partition of ^{137}Cs in surface air. ——, U.S.S.R., 1961; - - - U.S.S.R., 1962; —·—·, U.S., 1962

the final values attained are appreciably higher, as was to be expected according to the previous discussion. The value of the ratio of 25 : 1 to 30 : 1 observed from July 1963 onward is in keeping with the *Ash Can* observations made during the spring of 1962. The total 1961 ^{137}Cs was then further divided into that associated with ^{54}Mn, using a Mn/Cs ratio of 40 : 1, and that fraction which was not, the latter being called the residual ^{137}Cs. Results of this final partition are also illustrated in Fig. 3. It is of interest to note that the peak concentration of the residual ^{137}Cs in 1963 now occurs in May and June rather than in June and July, as shown for the total 1961 ^{137}Cs. The use of a higher ^{54}Mn/^{137}Cs ratio would have the same effect.

It thus appears that in 1961 and again in 1963 there was appreciable ^{137}Cs of high-altitude origin present in surface air. It is difficult to demonstrate by means of tracers that the same was true in 1962. One might consider, however, that by the spring of 1962 the ^{54}Mn may not yet have been well mixed with other debris existing at the same altitude which derived from different sources. The transport of such debris might be the same as for that mixed with ^{54}Mn. This would imply that one might use a smaller value of the Mn/Cs ratio, which would have the effect of causing the spring peak of the residual ^{137}Cs to occur earlier in 1962. One may postulate similar circumstances in 1963 involving debris from the 1962 polar tests for which a unique tracer has not yet been observed.

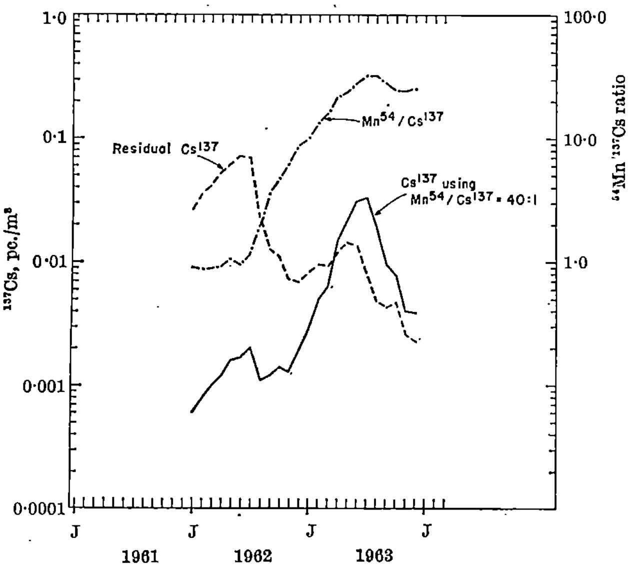

Fig. 3. ^{137}Cs from 1961 tests and ^{54}Mn/^{137}Cs ratio. ——, ^{137}Cs derived from ^{54}Mn/^{137}Cs ratio; - - -, residual ^{137}Cs (^{137}Cs not associated with ^{54}Mn); —·—·, ratio of ^{54}Mn to total 1961 ^{137}Cs

It is not possible to ascertain from these measurements the reason why high-altitude debris is delayed in reaching the surface. It may be related to particle size, or perhaps directly to altitude and the resultant increased path between source and the surface of the Earth. Perhaps measurements of ^{54}Mn and other tracers such as ^{109}Cd during 1964 and subsequent years will help to elucidate the relationship between altitude of origin and the time of appearance of the peak concentrations in surface air. It may be that observations of a natural tracer such as ^{7}Be will be helpful in establishing whether this is actually an altitude effect, or is due to a more general change in meteorological conditions.

A further use may be made of the ^{137}Cs data, namely, that of estimating the levels of ^{137}Cs to be expected during 1964. In some respects conditions during 1963 and 1964 parallel those in 1959 and 1960, barring the perturbation introduced by relatively more debris of high-altitude origin at present. A comparison between the autumn minimum in 1959 and the spring maximum in 1960 applied to the minimum observed in 1963 leads to an estimate of ~ 0·060 pc./m^3 during the peak in 1964. Preliminary values of ^{137}Cs obtained during January, February, March and April 1964 were 0·036, 0·038, 0·060 and 0·065 pc./m^3, respectively. A month by month comparison with findings in 1963 would lead to an expected peak value of ~ 0·13 pc./m^3 in 1964. A maximum concentration of this order is also found by projecting the individual components illustrated in Figs. 1 through 3 into 1964. This was done by making the assumption that the 1962 Soviet debris will behave in 1964 as did the 1961 component in 1963. Furthermore, it was assumed that the 1961 ^{137}Cs associated with ^{54}Mn would reach the same level in 1964 as in 1963. Support for this latter assumption is based on the fact that the ^{102}Rh concentration in precipitation was approximately the same during 1961 and 1962 as observed at Westwood, New Jersey[15]. The result of such a projection is a peak value of ~ 0·11 pc./m^3 in 1964, which is approximately 70 per cent of the magnitude of the 1963 maximum.

This work was performed under the auspices of the U.S. Atomic Energy Commission. We thank Dr. J. Sedlet of the Industrial Hygiene and Safety Division of this Laboratory for the use of air filters from his collection network prior to September 1961.

INADEQUACY OF THERMAL INITIATION THEORY IN INTERPRETING THE RESULTS OF FISSION FRAGMENT IRRADIATION OF EXPLOSIVES AT ELEVATED TEMPERATURES

By Lieut. JAMES F. MALLAY, Lieut. HENRY J. PRASK and Dr. JOSEPH CERNY*
Explosives Laboratory, Feltman Research Laboratories, Picatinny Arsenal, Dover, New Jersey

CONSIDERABLE research has been carried out in recent years[1] to determine the basic requirements necessary to initiate an explosive. Most of the more extensive investigations have been made on the macroscopic behaviour of explosives and have been interpreted satisfactorily in terms of the classical 'hot-spot' model[2–6]. Several explosives have also been subjected to irradiation, but not until recently has a detailed analysis of this process been attempted.

Cerny and Kaufman[7] irradiated several explosives with pions to produce spherical hot spots less than 10^{-5} cm in diameter. In this work it was noted that no initiations occurred. However, it was shown that the high energy–density produced by pion capture (when assumed to quickly degrade to thermal energy)[8,9] should cause a temperature increase sufficient to initiate several of the irradiated explosives.

A comparative analysis of typical pion-capture and nuclear-fission events shows that in the latter process a higher energy–density occurs and hence a greater temperature increase. As discussed in detail elsewhere[7], the energy deposited by the Auger electrons and α-particles which arise from a 'typical' pion capture event produces a spherical hot spot. The intense ionization and excitation along a fission-fragment track, however, produce a high energy–density region of cylindrical geometry.

Irradiations of a few explosives have been performed with fission fragments[10,11] but no initiations have been observed. (The explosions of nitrogen iodide are apparently due to a surface effect rather than a thermal spike[12–14].) However, the calculations of Cerny and Kaufman[7] indicated that some of the more sensitive secondary explosives had not been investigated and that, surprisingly, the frequently investigated lead azide was not expected to initiate on this model.

The purpose of the work recorded here was to determine the behaviour of several of these more sensitive high explosives when irradiated with fission fragments at a controlled elevated temperature. Table 1 shows the temperature required to produce various degrees of decomposition in 10^{-11} sec (the characteristic time for heat dissipation) for all the explosives investigated. It is apparent that the strength of the thermal spike arising from the irradiation need not be great to produce appreciable heat from chemical decomposition. Then, by having the explosives at some elevated temperature, say, 150° C, the likelihood of an irradiation-induced initiation—according to the 'hot-spot' model—should be significantly increased. Table 1 also shows the temperatures used in the experiment. Four high purity (> 99 per cent) secondary explosives were investigated: pentaerythritol tetranitrate (PETN), hexahydro-1,3,5-trinitro-*s*-triazine (RDX), octahydro-1,3,5,7-tetranitro-*s*-tetrazine (HMX) and glyceryl trinitrate (nitroglycerin).

A variable temperature explosive container was used to heat the explosive samples. A small quantity (0·30 ml.) of an acidic solution containing californium-252 (3 per cent spontaneous fission) was added to 300 mg of each explosive. In the case of the three solid explosives the mixture for each pellet was then dried, mixed and pressed on to a 10 ml. thermocouple in right-cylindrical pellets approximately 0·25 in. in diameter and 0·25 in. high.

Table 1. TEMPERATURES REQUIRED FOR VARIOUS FRACTIONAL DECOMPOSITIONS

Explosive	Maximum possible temperature increase (Q/c) °C	Temperature of the explosive (°C) required to produce a decomposition of 1%	50%	99%	Experimental temperature °C
RDX	4,850	750	935	1,035	160
HMX	4,020	805	1,025	1,160	215
PETN	4,930	1,065	1,625	2,050	125
Nitroglycerin	5,380	640	815	920	180

These are the temperatures at which each of the explosives must be kept for 10^{-11} sec in order to produce 1, 50 and 99 per cent chemical decomposition; also listed are the temperature increases that would result from complete decomposition (Q/c), and the temperatures at which the irradiations were performed.

Each pellet was inserted in the container and heated on all surfaces except the top from room temperature to approximately 35° C below the melting-point of the explosive. The pellet was kept at this temperature for 30 min and then heated to ignition. The time to ignition, which ranged from 4 to 10 min, and the temperatures of the pellet and the container were recorded. Five pellets of each explosive were examined in this way. The behaviour of the explosive pellets containing californium-252 was compared with that of pellets of the same explosive prepared in an identical manner but without californium.

The amount of californium-252 in the pellets was determined by measuring the α-activity of small samples of the solution in a liquid scintillation counter. The spontaneous fission to α-decay ratio being known, it was possible to ascertain that at least three fissions per minute occurred in the explosive samples. Table 2 shows the parameters of typical light and heavy fission fragments for californium-252 (ref. 15).

Table 2. TYPICAL PARAMETERS FOR FISSION FRAGMENTS FROM THE SPONTANEOUS FISSION OF CALIFORNIUM-252

Parameter	Units	Light	Heavy
Mass (M)	A.M.U.	111	141
Energy (E)	MeV	100·5	78·0
Velocity (V)	cm/sec	$1{\cdot}32 \times 10^9$	$1{\cdot}03 \times 10^9$
Range (R)	μ of RDX	8·4	7·0
Charge (Z)	—	44	54

The liquid nitroglycerin samples were easier to irradiate since it was only necessary to add the solution containing the californium-252. The mixture was then placed into the container in a small beaker and the thermocouple immersed.

A second method of irradiation was also employed using californium-252 plated on small platinum foils. In this case, a foil was placed in direct contact with the top of the pellet (immersed in the case of nitroglycerin) and the pellet was heated as before. Similar procedures to those of the first method for controlled heating to ignition and measuring the activity were followed. The amount of radiation to which each pellet was exposed was determined to be 33 fragments per min, which was appreciably greater than that of the first method.

No differences between the response of the irradiated explosives and the standards were observed even though the former were exposed to 200–2,000 fission fragments. The 'hot' pellets showed no signs of accelerated decomposition (compared with the standards) either when held at the elevated temperature or when heated to ignition. Both types of pellets of an explosive ignited at the same temperature, in the same general manner, and in the same time—within the normal deviations for such measurements on explosives.

---

* Lawrence Radiation Laboratory, Berkeley, California.

Although the fission-fragment irradiation did not produce initiation of these explosives, a detailed quantitative analysis was made to determine the predicted behaviour within the framework of the 'hot-spot' model[2–6]. This model has enjoyed some success in explaining the behaviour of explosives on a macroscopic scale, but has not often[7] been used in detail in an analysis of microscale processes.

Initial 'temperature'-radius profiles for the hot spots, which in reality are energy-radius profiles, were obtained by calculating the energy deposited in successive cylindrical shells coaxial with the fission-fragment track. Such calculations are complicated, however, by lack of precise information on the relative amounts of energy that a stopping fission fragment loses to excitations and ionizations. Magee[16] discusses the ionization and excitation resulting from the passage of high-energy charged particles through matter and postulates that two processes—termed 'head-on' and 'glancing' collisions—make equal contributions to the differential energy loss of the particle. Using this model for the initial part of its track, we assume that a fission fragment would lose half its energy in producing δ-rays (knock-on electrons of energy, say, greater than 200 eV) and the other half in low-energy ionizations and excitations. This latter type of energy deposition was assumed to occur within 10 Å of the centre of the track[17]. Although the values chosen for the minimum δ-ray energy and the radial distance for lesser energy drops are somewhat arbitrary, it is evident[17,18] that 200 eV is of the correct order of magnitude for such a figure and that for the explosives investigated 10 Å is approximately the straight-line distance travelled by a 200-eV electron.

The relative number of δ-rays of a given energy that are produced by the fission fragment can be found using the relation of Mott as cited by Bradt and Peters[19]. This expression was normalized (over all possible energies) to one-half the value of a (dE/dx) which was calculated from the range–energy curves of Fulmer[20]. This particular (dE/dx) was chosen at the point along the track where the fragment had lost one-half its initial energy.

The electron range–energy relation used to find the energy deposited away from the track was that of Glocker as cited by Katz and Penfold[21]. To account for the fact that such slow electrons do not move out in a straight line nor in a plane perpendicular to the fragment track, one-half the practical range as given by Glocker was used as an average, or effective, range[22–25].

The time required for the passage of a fission fragment and its subsequent energy deposition is of interest. For a section of the track where *l-d*-100 Å, the passage of the fragment through this region and the stopping of the low-energy δ-rays should occur in appreciably less than 10^{-13} sec. Hence we may assume that the initial energy distribution arises in 10^{-13} sec.

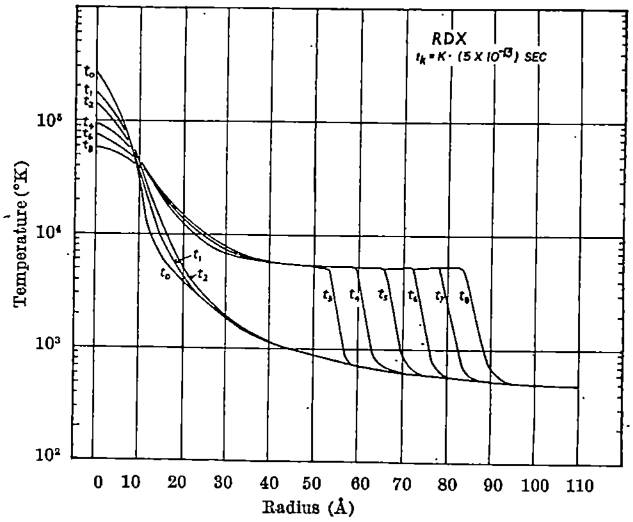

Fig. 1. Temperature versus radius profiles for various times following the passage of the fission fragment through RDX. t_k represents a time period of k times the interval 5×10^{-13} sec

For a first-order reaction the subsequent time-behaviour of the (cylindrical) hot spot is governed by the heat-diffusion equation:

$$\frac{\partial T}{\partial t} = \varkappa \nabla^2 T = \frac{Q}{c} n Z e^{-E/RT} \tag{1}$$

where T is the absolute temperature, t is the time, $\varkappa$ is the thermal diffusivity, Q is the heat of reaction, c is the specific heat, n is the mass fraction of unconsumed reactant, Z is the Arrhenius pre-exponential factor, E is the activation energy, and R is the gas constant. Also, $\varkappa = k/\rho c$, where k is the thermal conductivity and ρ is the density. These constants are listed in Table 3 for the explosives investigated.

Solutions to equation (1) for later times were obtained consistent with the initial temperature profile and subsequent reactant consumption. The method used was an extension of the Schmidt method modified to include the heat liberated by chemical reaction[37]. The material was divided into a series of concentric cylindrical shells, the temperature of each shell being uniform, and the temperatures of the various shells determined by the initial temperature–radius profiles (Figs. 1–3). The temperature for the i^{th} shell, T_i, at time $t + \Delta t$ was then obtained from the temperatures at time t by the approximation:

$$T_i(t + \Delta t) = \left\{\frac{\varkappa}{(\Delta r)^2}\left(1 - \frac{\Delta r}{2r_i}\right)[T_{i-1}(t) - T_i(t)] - \frac{\varkappa}{(\Delta r)^2}\left(1 + \frac{\Delta r}{2r_i}\right) x \; x\,[T_i(t) - T_{i+1}(t)] + \frac{O}{c} n_i(t) Z\right\} \Delta t + T_i(t) \tag{2}$$

Table 3. PHYSICAL CONSTANTS OF THE EXPLOSIVES

* Cook and Abegg, recognizing the autocatalytic nature of PETN, extrapolated to find the 'unimolecular' (first order) initial rate for the reaction. This, of course, becomes considerably faster in the presence of its decomposition products.

† The values for the density (ρ) and the thermal conductivity (k) of RDX and HMX were set equal because of their similar chemical character and due to lack of consistent data for the pure materials.

‡ Johnson (ref. 35) cites Q_L for HMX as 1,356 cal/gm from *Explosion Effects Data Sheets, NAVORD Rep* 2896 (*NOL*), June 14, 1955 (addendum of 1956). However, Tonegutti (ref. 27) points out that the difference between Q_L and Q_V for RDX is 90 cal/gm. Assuming the same relationship for HMX (since Q_L is nearly the same—as are most of the properties), we obtain 1,266 cal/gm for Q_V for HMX.

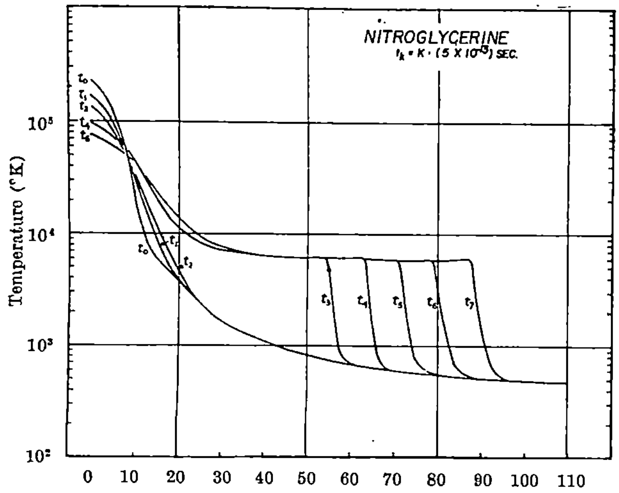

Fig. 2. Temperature versus radius profiles for various times following the passage of the fission fragment through nitroglycerin. t_k represents a time period of k times the interval 5×10^{-13} sec

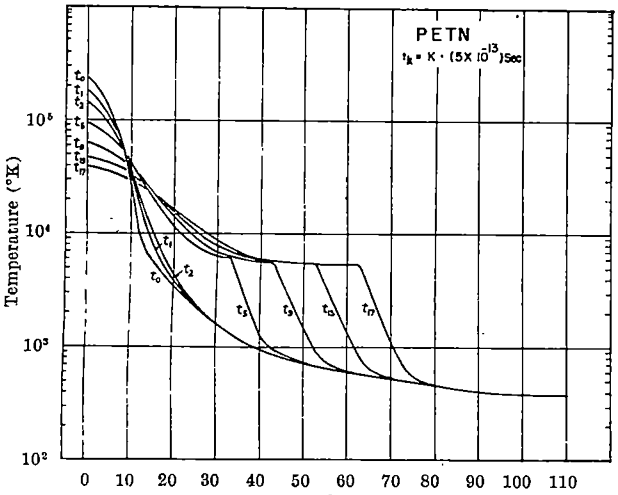

Fig. 3. Temperature versus radius profiles for various times following the passage of the fission fragment through PETN. t_k represents a time period of k times the interval 5×10^{-13} sec

where Δr is the thickness of each cylindrical shell and r_i is the radius to the centre of the i^{th} shell.

We have assumed that since molecular vibration frequencies are $\sim 10^{13}$/sec, it is possible to have the initial energy profile transformed into a temperature profile by 10^{-12} sec. Secondly, we have assumed that this transition from an energy-radius to a temperature-radius distribution can be estimated by using equation (1) neglecting chemical reaction. After 10^{-12} sec the complete solution to equation (2) is obtained. The temperature-radius profiles were calculated using an I.B.M. 709 digital computer. Equation (2) was solved for a series of time-intervals, Δt, chosen such that the temperature change in any shell during the time-interval was less than 5 per cent; the shell thickness, Δr, was taken to be 5 Å. The results for RDX, nitroglycerin and PETN are shown in Figs. 1, 2 and 3, respectively, with initiation predicted in all cases. The behaviour of HMX is expected to follow very closely that for RDX.

An alternative approach was used to check the sensitivity of the results to a variation in the initial energy–radius profile. In this case, energy deposition was assumed to be due to δ-rays alone so that the temperatures for the first three shells (15 Å) were essentially identical ($\sim$ 1·4 × 10 °C in RDX). These calculations also predicted that initiation should occur in each explosive in much the same manner as in the initial case. Although initiation is predicted for all the explosives investigated, such is not the case for explosives in general, as was shown previously[7].

The thermochemical and physical data used in the calculations are listed in Table 3. It was assumed that the thermal conductivity and specific heat were temperature independent, and further that the specific heat of the products of reaction was the same as that of the original explosive. Macroscopic thermal parameters were used throughout, as in previous work, due to the lack of contradictory information[38].

These results show once more the inadequacy of the 'hot-spot' model in describing the effects of microscale events in explosive materials. It should be noted that Bowden and Yoffe[1] have postulated that a critical size of 10^{-5}–10^{-3} cm must be exceeded before the model is applicable; however, it is not apparent from the mathematical model itself just how this limitation comes about. Two theories have been proposed recently which when applied to our experimental conditions appear to yield results consistent with ours. A recent estimate has been made by Dodd[39] using a statistical approach which indicates that the simultaneous decomposition of the order of only ten molecules is sufficient for initiation to occur. Secondly, a statistical model has also been used by Ling[40] to describe initiation phenomena. In applying this model to the case of fission-fragment irradiations, he finds that for temperatures of 200°–400° C in the volume around the track, initiation is unlikely. It appears, however, that if his calculations were extended to include the higher temperatures indicated in this work (say, 1,500° C in a 100-Å radius cylindrical volume), this model would also predict that initiation is likely.

On the other hand, some of the assumptions made in our work are open to question. The extrapolation of kinetic data to these conditions is unavoidable but possibly erroneous. Certainly the processes involved in the conversion of energy to temperature and their interrelation with chemical reaction are not well understood when considered on this time scale[41]. It is conceivable, as noted in shock-wave experiments[42,43], that a delay may exist between the time at which a temperature distribution is established and the beginning of chemical reaction. It should also be noted that calculations on atomic displacements in copper indicate that heat dissipation may occur more rapidly in microscale events than would be expected from classical heat conduction[44]. If there were an analogy, such an effect in explosives would considerably alter our calculations. Lacking more precise information concerning the assumptions made, however, it appears that the 'hot-spot' model may require considerable revision to account for experimental data on explosive irradiations.

We thank Dr. Harold J. Matsuguma for his assistance in the preparation of the experiment.

THIS attempt to calculate the temperature and the behaviour of a hot spot formed in an explosive crystal by the passage of a fission fragment is a courageous one, but is fraught with some danger.

It is true that the energy which a fission fragment dissipates within a crystalline material is delivered to the lattice, but the rate and the way in which it appears as lattice vibrations (heat) are complex and poorly understood processes. The two major way in which energy is lost are those of fragment/electron interactions (in a Coulomb fashion) and those of fragment/nucleus collisions (in a Rutherford fashion). The division of energy-loss to these two processes is sensitively dependent on the nature of the theoretical model chosen for the atomic interaction potential. Since a considerable amount of the energy delivered directly to the lattice atoms may be carried long distances down close-packed rows of atoms or molecules at shock-wave velocities, the temperatures produced at the centre of the track may well be less than 25 per cent of those suggested by the authors. Moreover, since the diameter of the tube is only 10 Å (approximately 6 atoms) the material should not be considered as a continuum, and it has been shown that the effective thermal conductivity may be greater than the macroscopic conductivity by a factor as large as 10.

The rate at which heat is evolved owing to chemical reaction is proportional to the rate constant, which the authors take as about 10^{20}/sec by extrapolating low-temperature kinetic data over 10^5 °C. This extrapolation is open to some criticism and in fact the rate constant is more likely to be of the order of 10^{14}/sec, that is, the same order of magnitude as the lattice vibration frequency. Hence it is possible that the ratio:

$$\frac{\text{heat evolved due to chemical reaction}}{\text{heat lost due to conduction}}$$

has been overestimated by many orders of magnitude. In addition, the computed temperature profiles would not necessarily lead to a macroscopic explosion. In all three figures the putative flame front is heavily supported from behind (nearer to the particle trajectory) by an intense 'hot spot' (radius approx. 20 Å, temperature greater than 2×10^4 °K). If the calculations were continued until this hot spot became significantly eroded, would the flame front continue to propagate unsupported ?

The critical hot spot size between 10^{-5} and 10^{-3} cm is partly derived on a theoretical basis but mainly from relatively macroscopic experimental observations. Although there is no *a priori* reason why the theory should not be valid outside this range, the theory should not be taken too far. First of all the number of molecules involved in the excitation of a typical track is small and an atomistic approach may be necessary. Secondly, there is the problem of the growth to explosion from the region of initiation. This growth stage can be a delicate one and under many conditions may be quenched.

The scope of classical explosion theory is more modest than the authors imply. It is customary to calculate the evolution of the temperature profile from the basic equation until the end of the induction period, that is, from $\theta = 0$ to $\theta_{.} \sim 2$, where θ is the Frank–Kamenetski reduced temperature increase $E(T - T_0)/RT_0^2$. Neglect of hydrodynamic processes is justified in this case for the conventional explosives because the ratio, temperature increase/adiabatic explosion temperature, cRT_0^2/qE, and thus the fractional decomposition is small ($\sim$ 5 per cent). Thus the classical theory enables us to determine whether a hot spot grows or decays in its early life but cannot be applied to considerations of its subsequent fate.

In conclusion we would agree with the title of this article that there is an inadequacy of thermal explosion theory when applied to fission-fragment bombardment of explosive solids. It would seem, however, that it is not possible to make sensible calculations at this stage since the necessary parameters under these extreme conditions are not known.

SPECTRUM-LINE-REVERSAL TEMPERATURE MEASUREMENTS THROUGH UNSTEADY RAREFACTION WAVES IN VIBRATIONALLY RELAXING OXYGEN

By DR. T. A. HOLBECHE
Aerodynamics Department, Royal Aircraft Establishment, Farnborough, Hants

THIS article describes some preliminary investigations of the effect of vibrational relaxation on the structure of unsteady expansion waves produced in a shock tube by the bursting of a second diaphragm. Fig. 1 illustrates in distance–time co-ordinates the idealized flow pattern which would result from instantaneous rupture of this diaphragm by the initial (or primary) shock. The expansion being investigated takes place in the gas heated by the initial shock; in other words, behind the secondary contact surface. By a measurement of the time-variation of temperature and of static pressure at some fixed point *B*, the effect of the lag in vibrational de-excitation (and

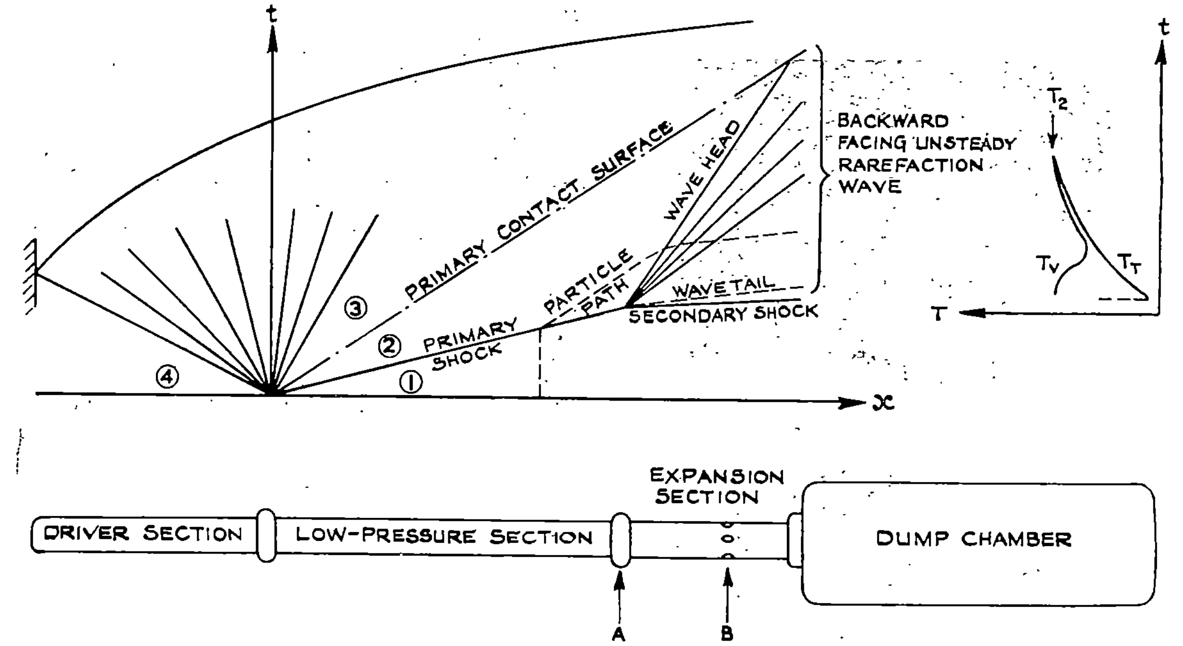

Fig. 1. Schematic diagram of idealized flow geometry in x–t plane. A, Second diaphragm position; B, observation position; T_V, T_T, vibrational and translational temperature at B; T_2, equilibrium temperature of shock-heated gas

of any chemical recombination as well) induced by the rapid cooling in the expansion wave can be followed. In this application the unsteady expansion has the particular advantage, compared with the steady Prandtl–Meyer configuration, for example, that a much higher degree of expansion is possible, thus allowing examination of rate processes over a wide temperature range. As in the case of steady non-equilibrium flows, the static pressure-level is relatively insensitive to internal relaxation effects despite their effect on the flow temperature. Thus a measurement of pressure can be used to check the flow geometry.

The experiments were carried out in a 2-in.-diam. hydrogen-driven shock tube fitted with a second diaphragm of 0·0076-mm thick aluminium foil: this separated the 15-ft. long low-pressure section from a 2-ft. long constant-area evacuated expansion section, also of 2 in. internal diameter. A large dump chamber was used to avoid reflected disturbances.

The oxygen test-gas was at an initial pressure of 10 torr (mm mercury), and the primary shock Mach numbers measured at the second diaphragm position were in the region of 7·0. In the absence of attenuation effects and diaphragm opening delays, this would provide an initial equilibrium state of the oxygen at a temperature of about 2,500° K and a pressure of about 600 torr, and with about 14 per cent (the maximum possible) of the static enthalpy residing in the vibrational mode. Although under these conditions the degree of dissociation was about 1 per cent, it was effectively frozen during the experiment, thus leaving vibrational relaxation as the dominant non-equilibrium process in the expansion wave. Oxygen was chosen as the test gas for this first phase of investigation since its vibrational relaxation time was short enough to allow observation of the expansion wave structure within the shock tube running time.

The temperature variation through the wave was measured by the double beam sodium-line-reversal method developed by Clouston, Gaydon and Hurle[1,2]. There is much evidence from temperature measurements behind shock waves[2,3] and in steady expansive flows in nozzles[4,5] that this technique measures the molecular vibrational temperature directly and so enables the effect of any lag in vibrational excitation or de-excitation to be followed. In the work recorded here, the Pointolite background temperatures were set at about 2,000° K and 2,400° K to bracket the expected variation of vibrational temperature. This resulted in an emission signal on one beam and an absorption signal on the other, and enabled the temperature variation to be followed with better accuracy than by extrapolation from dual emission or dual absorption records. The time resolution was about 5 μsec. The static pressure variation was measured with a miniature piezo-electric transducer having a rise time of about 10 μsec. More complete details of the experimental arrangements are given elsewhere[6].

A typical pair of simultaneously recorded temperature and pressure oscillograms is shown in Fig. 2; about twelve runs in oxygen were recorded, the initial conditions being held as nearly as possible the same for all. Fig. 2*a* shows the time variation of the intensity of the sodium *D*-line radiation against background brightness temperatures of 2,005° K and 2,390° K on the upper and lower beams respectively recorded at a distance of 15·5 in. from the second diaphragm station. Emission causes a downward deflexion and absorption an upward deflexion. The upper trace shows a gradually increasing emission signal commencing from the 'spike' due to the secondary shock marking the start or 'tail' of the expansion wave. The lower trace shows an absorption signal increasing to a maximum from this point and then falling. Both traces show a discontinuity with passage of the primary contact surface.

In the temperature analysis of Fig. 3*a* a comparison is made between the experimental temperature history (open symbols) derived from Fig. 2*a* and theoretical vibrational and translational temperature profiles calculated by Appleton's method[7,8] for comparable initial conditions. For the purpose of this comparison, the time origin of the temperature oscillogram was taken to be the instant when the primary shock reached the second diaphragm determined by extrapolation of the shock speed versus distance data.

There is a striking similarity between the profiles, suggesting that the observed spectrum-line-reversal temperature is essentially the same as the vibrational temperature of the oxygen molecules for the present experimental conditions. The experimental temperature minimum occurs, however, some 20–25 μsec later than expected, and the temperature itself is about 250° K higher than the theoretical value; moreover, the time-scale of the observed temperature variation is shorter than

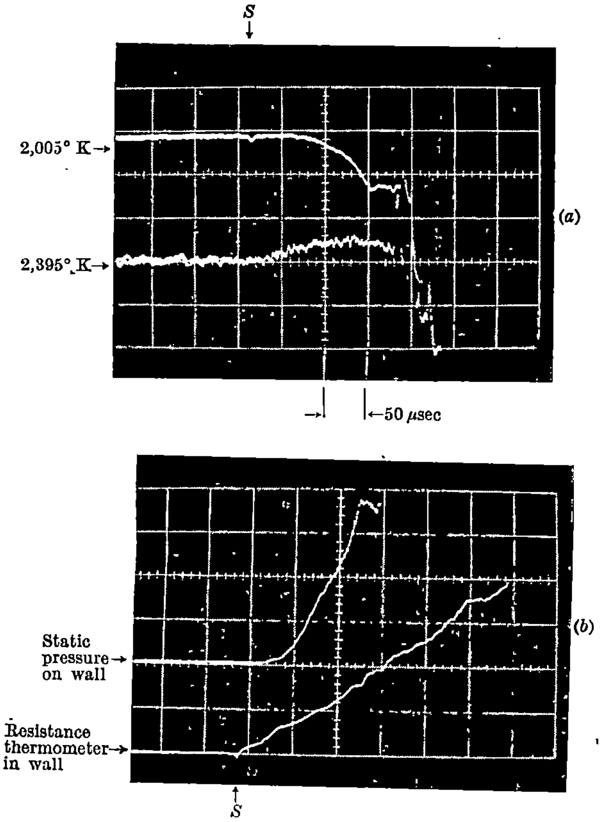

Fig. 2. Typical temperature and pressure oscillograms for unsteady expansion of shock-heated oxygen. Initial conditions, M_s, 6·86; T_s, =2,449° K, p_s, 559·5 torr; (a) X, 15·5 in. (b) X, 12·5 in. The arrow S denotes passage of the secondary shock

that of the theoretical. The significance of these small discrepancies is discussed later, but they may in part arise from the delay in rupture of the weak diaphragm with a consequent modification of the flow geometry; this might be expected to affect the pressure variation as well. Fig. 2b shows the pressure and thin-film gauge signals recorded at a point on the wall 12·5 in. from the second diaphragm. Analysis of the oscillogram showed that the experimental pressure signal was also delayed, and its rate of rise greater than predicted and with a time-scale again less than that calculated (Fig. 3b).

The 'breakaway' and subsequent rise of the spectrum-line-reversal temperature towards a 'frozen' value observed in these experiments shows that while the electronic excitation temperature of the sodium is not coupled to the molecular translational temperature its value is consistent with the supposition that it is the vibrational temperature of the relaxing oxygen that is being measured by this means.

The existence of a minimum value of the vibrational temperature beyond which it again increases (first pointed out on theoretical grounds by Stulov[9] for dissociational relaxation) is a characteristic feature of the wave structure, and therefore the present results lend at least qualitative support to the calculations of Appleton and Stulov.

On account of the low density there was insufficient sodium radiation present in these experiments to permit accurate measurement of temperature as far back in the flow as the fully frozen region, although the observed temperature began to climb towards it. Runs at higher initial pressure which would have made this possible were, however, not attempted with oxygen because of the risk of ignition at the driving interface. Comparable runs in nitrogen at initial pressures of up to 100 torr should overcome this limitation since the D-line radiancy ($\alpha\rho^{1/2}$) would then be greater by a factor of roughly $\sqrt{10}$. Together with the use of interference filters of increased transmission (factor of 3) and more sensitive photomultipliers, now available, the overall signal-to-noise ratio could be improved by a factor of at least 10. This should not only enable detection of the 'frozen' vibrational temperature but will also incidentally extend the measureable temperature range to below 1,800° K.

A further important experimental reason for raising the density is that the sodium radiation may be collision-limited in the 'frozen' region of the expansion, leading in this case to spuriously high observed temperatures. This may arise if the excited vibrational levels of the oxygen molecules are depopulated by transfer of energy to the electronic levels of the sodium atoms which then radiate, rather than by the binary collisions assumed in the theoretical description. Here again, nitrogen is to be preferred to oxygen as a test gas since spectroscopic data for collisions between nitrogen and excited sodium exist[10].

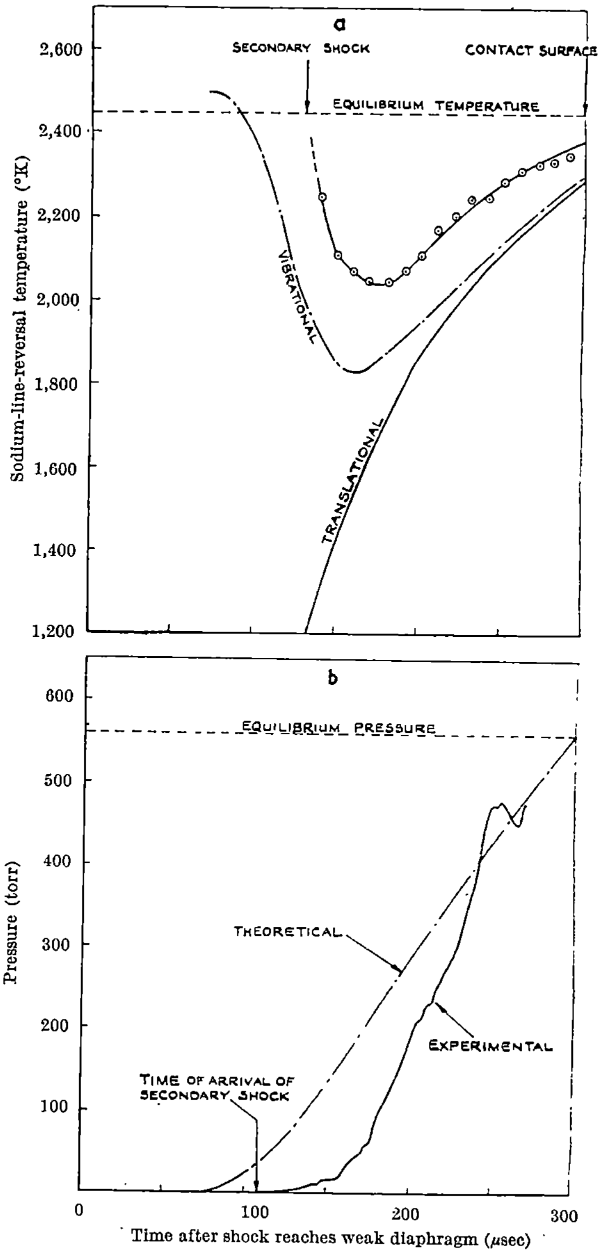

Fig. 3. a, Temperature analysis of Fig. 2a. The theoretical vibrational and translational temperature profiles are for slightly different initial conditions, namely, M_s, 6·96, T_s, 2,492° K, p_s, 585 torr, X, 15·5 in.; b, pressure analysis of Fig. 2b. Theoretical curve for same initial conditions as for Fig. 3a but with X, 12·5 in.

Evidently Kirchhoff's Law will not apply in this region, and an experimental indication of this was that meaningful gas temperatures could not be derived from the ratio of the double-beam signals. This small region round the tail of the expansion wave corresponds to the dashed portion of the experimental temperature profile in Fig. 3*a*.

Allowing for the diaphragm opening delay already referred to, the general agreement between theoretical and experimental profiles obtained shows that the picture of the flow pattern derived from theory is broadly correct, though the degree to which the wave is centred has not been investigated; it is hoped to check this in later work in which measurements will be taken at two downstream positions simultaneously. To avoid spurious distortion of the temperature and pressure profiles due to shock attenuation, a larger diameter shock tube would be desirable.

The observed shock attenuation would have led one to expect temperatures in the region of the contact surface above the equilibrium value, based on the shock speed at the second diaphragm position. In fact, however, in all runs, values less than equilibrium were recorded (Fig. 3*a*).

This may indicate that the running time was not quite sufficient for equilibrium to be reached, but may also be a further illustration of an effect peculiar to spectrum-line-reversal measurements using sodium in hot oxygen observed in some earlier work and not yet explained[11,12]. It was found that while changes of temperature were accurately followed, the temperature values were low by constant systematic amounts ranging up to nearly 400° K in some cases. This effect was not present with sodium in nitrogen.

The present work is of interest in relation to some recent spectrum-line-reversal temperature measurements obtained by Hurle, Russo and Hall[13], in a steady nozzle expansion where it was necessary to postulate a relaxation time for de-excitation of nitrogen fifteen times shorter than that derived from vibrational excitation investigations behind strong normal shock waves. From this they suggest that the Landau–Teller description of vibrational de-excitation may be inapplicable in non-equilibrium situations where the difference between vibrational and translational energy is large, and that the shorter relaxation time indicates that the probability of de-excitation may depend on the vibrational as well as on the translational energy of the colliding molecules.

The present results, however, suggest that for the oxygen relaxation observed in these experiments such assumptions are unnecessary. The general agreement seen with Appleton's calculations implies that his description of the relaxation process was adequate; he used a linear rate equation, Camac's experimental data (from shock wave investigations)[14], and Landau–Teller theory.

The consequences of large changes of the effective relaxation time on the temperature profiles of unsteady expansion waves in nitrogen have been looked into theoretically by Woodley[8]. He has found that a substantial increase in the rate of vibrational de-excitation (of the order of that mentioned by Hurle *et al.*) will shift the temperature minimum to earlier times and reduce its value considerably as might be qualitatively expected. This effect was not observed in the present experiments with oxygen, the results of which are consistent with the accepted value for the effective relaxation time within a factor of two. In fact, the experimental observation of temperatures above theoretical (Fig. 3*a*) might on the contrary, suggest that de-excitation proceeds more slowly than was assumed. According to Appleton's argument, the assumption of frozen dissociation in these experiments is justified, so that the enthalpy of recombination of the oxygen atoms in the wave cannot contribute to the vibrational temperature. A possibility that was considered was that these higher temperatures were due to reflected sodium light entering the photo-multipliers, but this seems unlikely since the aperture of the optical system was small and earlier work[12] involving temperature measurements of the incident shock never at any time revealed a sodium radiation signal preceding the shock.

Extension of this work to reacting gases with the view of measuring the temperature dependence of recombination rates is feasible and might incidentally show whether coupling between the rates of vibrational and chemical relaxation is significant.

The use of unsteady expansion waves for chemical kinetic measurements in shock tubes was suggested by A. R. Fairbairn (1958) in an unpublished Ministry of Aviation note, and the experiment in its present form arose from discussions with D. A. Spence. J. P. Appleton performed the calculations reported in ref. 7 in support of this work, and I am indebted to J. G. Woodley for the further computations in Fig. 3.

RHYTHMIC ALTERNATIONS IN THE RATE OF SYNTHESIS AND THE COMPOSITION OF RAPIDLY LABELLED RIBONUCLEIC ACID DURING THE SYNCHRONOUS GROWTH OF BACTERIA

By Dr. RIVKA RUDNER, Mrs. BARBARA PROKOP-SCHNEIDER and Prof. ERWIN CHARGAFF

Cell Chemistry Laboratory, Department of Biochemistry, College of Physicians and Surgeons, Columbia University, New York

We have observed that a remarkable wave pattern of rate of synthesis and of composition results when the ribonucleic acid newly formed in consecutive segments of the generation period of a synchronously growing bacterial culture is examined. A donor strain of *Escherichia coli K*-12 (*HfrH*) was used in these experiments.

Recent observations on *Hfr* strains of *E. coli*[1] and on certain strains of *Bacillus subtilis*[2], and also some autoradiographic evidence[3], which suggested a sequential, unidirectional replication of bacterial chromosomes, starting from a single growing point, determined the choice of organism for the work recorded here. If the

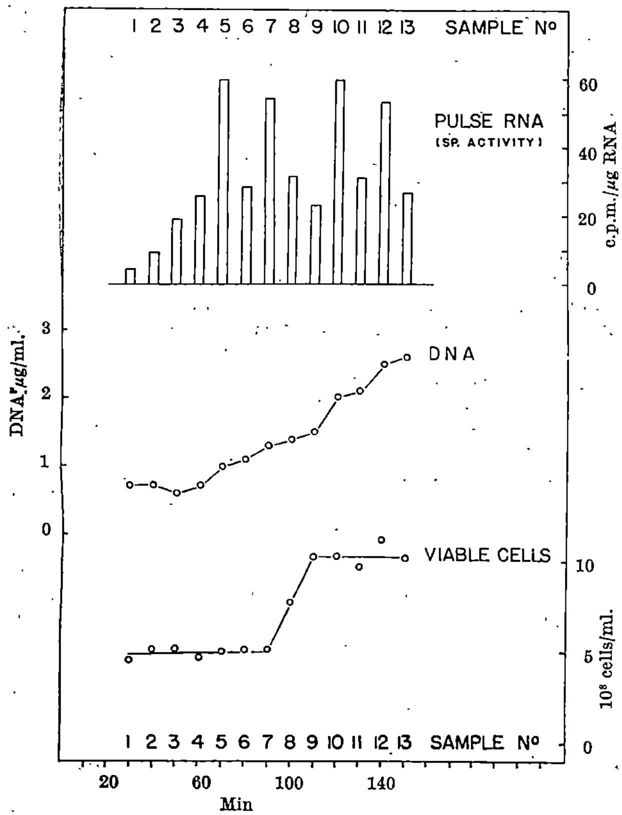

Fig. 1. Synchronous growth of *E. coli HfrH* (m^-, λ, 424), Exp. 1. The samples, taken at intervals of ten minutes, are numbered as in Table 1. The diagrams represent, in upward order: (*a*) viable counts, determined by plating the cells in appropriate dilutions on plates of nutrient agar; (*b*) synthesis of DNA; (*c*) specific activity of pulse-labelled RNA

function of the DNA component of a chromosome is taken to consist in its ability to conserve genetic information (through the duplication of DNA) and to convey it (perhaps through the production of specific RNA molecules), and if the first of these processes advances along the chromosome in an orderly and successive manner, it is not unreasonable to assume that the second does so too. In this event, the rate of synthesis, and the nucleotide composition, of different species of RNA, produced in different intervals within a growth cycle, could well vary. Furthermore, the synthesis of ribosomal and transfer RNA could be expected to occur in a periodic fashion either before or after the replication of those sites on the genome that may determine these RNA species. In order to explore these possibilities, a synchronously dividing population of *E. coli* was subjected to a pulse of ^{32}P-phosphate at regular intervals; the rate of synthesis and the composition of the newly formed RNA were then determined.

The organism examined was an *HfrH* (λ, 424) strain requiring methionine obtained from Dr. T. Nagata, who had shown that the genome of this strain replicates in a sequential, polarized fashion from the *F* locus forward[1]. The bacteria were grown in a *tris*-salts medium[4] to which were added, per litre of medium, 87·1 mg dihydrogen potassium phosphate, 300 mg 'vitamin-free' casamino acids, 50 mg L-methionine, and 2 g glucose. The cells were synchronized by 'fractional filtration'[5], and the filtrate comprising the small cell fraction was incubated in fresh, previously warmed, medium at 37°. Samples were withdrawn from the master culture every 10 min for the following operations: (*a*) 0·1 ml. for viable counts; (*b*) to 1 ml. of chilled 50 per cent trichloroacetic acid solution 9 ml. of the culture were added, and DNA was determined in the precipitate by the diphenylamine reaction[6] (in Exp. 2, RNA was also determined by means of the orcinol reaction); (*c*) a sample of 100 ml. of the culture was exposed to 2-mc. carrier-free ^{32}P-orthophosphate for 80 sec when, in order to terminate the pulse, the cells were poured on crushed ice. The bacteria were then washed to remove extraneous radiophosphate and 1 g (wet weight) of unlabelled *HfrH* cells grown in the same medium was added as carrier. After the extraction of RNA by a modification of several known procedures utilizing 'Duponol' and phenol, determination of radioactivity, and hydrolysis with alkali in the usual manner the (2′ + 3′)-nucleotides were separated by two-dimensional chromatography[7] and estimated spectrophotometrically and by measurement of their radioactivity. The figures for newly formed RNA were expressed as c.p.m./μg of RNA; the estimates of the RNA content of the several preparations were again derived from spectrophotometry. Correction was made for non-nucleotidic ^{32}P-compounds that accompany the RNA specimens in varying amounts (20–30 per cent of the radiophosphate incorporated in a non-dialysable form) through the summation of counts recorded for the purified mononucleotide components.

Figs. 1 and 2 depict, in two independent experiments, the synchronism of cell division in the bacterial culture; the increase in the level of DNA during growth; and the patterns of synthesis of new RNA revealed by the application of a series of short pulses of ^{32}P-phosphate to consecutive segments of the generation period. In addition, the rise of the levels of RNA in the master culture of Exp. 2 and the computed total counts of RNA present in the

† About 1 mg of RNA was hydrolysed with 0·2 ml. of 0·5 N aqueous potassium hydroxide for 20 h at 37°. After separation by two-dimensional paper chromatography, the radioactivity of each (2′ + 3′)-nucleotide was measured in a gas flow counter. The figures express the distribution of phosphorus-32 incorporated into each nucleotide as per cent of total radioactivity, that is, of the summation of all counts given by the sample. The standard deviation ranged from 0·25 to 0·94. In sample No. 1 the counts were too low for calculation. The figures in italics denote the samples for which bursts of RNA synthesis were recorded (see Fig. 1). The three columns of molar ratios list the ratio of purines to pyrimidines, the dissymmetry ratio, and the ratio of 6-amino to 6-keto nucleotides, respectively. Compare Table 3 for the composition of bacterial DNA and RNA. Abbreviations: A, adenylic acid; G, guanylic acid; C, cytidylic acid; U, uridylic acid.

* See Fig. 2 for additional results and Table 1 for explanations.

15 pulsed samples are shown in Fig. 2. As concerns the synthesis of DNA, it exhibits a definite retardation at the outset and then proceeds in what would appear to be a stepwise manner (usually two steps in a growth cycle) interrupted by periods of almost no synthesis. It would have been possible to fit a straight line to most of the points indicating the DNA levels; but we believe that our observations represent meaningful variations.

During the initial lag of DNA formation new RNA molecules are apparently produced, in accordance with previous observations[8,9]. RNA is synthesized continually; but when the rates of synthesis are probed into at different points of the growth cycle, rhythmic fluctuations are seen. These are shown graphically in Figs. 1 and 2 in the form of the specific activity of the RNA. At the onset of the growth cycle the increase in the rates of synthesis of RNA, as measured by the uptake of phosphorus-32, was nearly linear; thereafter, the specific activities of pulse-labelled RNA alternated between high and low levels, two bursts being discernible during an average generation time of 70 min (Fig. 1). In another experiment, in which the generation time was somewhat shorter, only one peak was noticed in the first complete generation period under observation (sample No. 6 in Fig. 2). These bursts of RNA synthesis seem to be regularly spaced with respect to DNA replication, occurring generally in the strain under investigation here when DNA had increased by 40–45 per cent and 75–85 per cent. (Compare samples No. 5, 7, 10, 12 in Fig. 1 and No. 2, 6, 12 and 14 in Fig. 2.)

These alternations of the rates of RNA synthesis were found to be associated with remarkable changes in the apparent composition of the newly made RNA molecules. This information will be found in Tables 1 and 2 which list, in addition to figures on the percentage increase in DNA and the total counts recovered in the isolated RNA specimens, the distribution of radioactivity among the (2′ + 3′)-nucleotide components of each RNA sample. These values, it will be remembered, describe the RNA made in the course of a short period of exposure to phosphorus-32, by synchronously multiplying cells at different stages of their cellular history. For purposes of comparison it may be useful to consider these figures in conjunction with those listed in Table 3, in which data on the composition of the DNA and of various RNA fractions of the bacterial strain are presented. It will be noticed that the DNA contains, of course, equal molar quantities of purine and of pyrimidine nucleotides, whereas in the ribosomal and also in the total RNA the molar concentration of purine nucleotides surpasses that of pyrimidine nucleotides by 25 per cent or more.

If, with this in mind, the values compiled in Tables 1 and 2 are scrutinized, two principal groups of composition will emerge. One group, with a ratio of purines to pyrimidines of 1·2 or higher, comprises all those RNA specimens the synthesis of which coincided with the peaks of incor-

Table 3. COMPOSITION OF DNA AND RNA OF *E. coli HfrH**

* T denotes thymidylic acid; other abbreviations as in Table 1. The figures for total RNA represent the averages of the spectrophotometric analyses of the nucleotide composition of the 13 RNA samples collected in Exp. 1 (Table 1) and of the 15 RNA samples of Exp. 2 (Table 2). The specimens of ribosomal and transfer RNA were separated by means of a linear gradient of sodium chloride on a column of methylated serum albumin–kieselguhr (ref. 10).

poration of phosphorus-32, that is, samples No. 5, 7, 10, 12 in Table 1 and Fig. 1; samples No. 2, 6, 12, 14 in Table 2 and Fig. 2. These specimens are altogether quite similar in composition—if one were to judge from the results of the distribution of phosphorus-32 in their constituent nucleotides—to that of total or ribosomal RNA. The base-pairing characteristic of DNA is entirely absent. Guanylic acid is the preponderant nucleotide, with the ratio of guanylic to cytidylic acids 1·3 or higher in nearly all instances.

The other group is less homogeneous in appearance, though many specimens share the property of exhibiting molar equivalence with respect to at least one of the two base-pairs: the ratio of adenylic to uridylic acids is near one in samples No. 6, 8, 11 in Table 1 and in samples No. 5 and 15 in Table 2. Similarly, guanylic and cytidylic acids are nearly equimolecular in samples No. 4 and 9 in Table 1, and in samples No. 4, 8, 10 and 13 in Table 2. In a recent paper from this laboratory it was pointed out that the occurrence of only partial base-pairing seems to hold true of most messenger-RNA preparations described in the literature[11].

There are several samples of pulse-labelled RNA in our list that could be regarded as quite similar to *E. coli* DNA in base proportions, particularly samples No. 3 and 13 in Table 1; the examples in Table 2 are less convincing, but samples No. 8, 13, and 15 could be cited. If another characteristic of DNA is adduced, namely, the equimolarity of purines and pyrimidines, samples No. 3, 4, 9, 13 in Table 1, and No. 8, 13, 15 in Table 2 may be said to resemble DNA in this respect. One receives the impression that, on the whole, the pulse-labelled RNA specimens produced at the beginning or at the end of a growth cycle, when DNA synthesis has not yet begun or has tapered off, are more similar to DNA in composition than those made at other periods.

There are other possible correlations, though the experimental material is not large enough for certainty. When DNA has increased by about 10 per cent, the distribution of the label in the RNA made at this stage is very similar in both experiments (compare samples No. 4 and 9 in Table 1, and No. 9 in Table 2). Another RNA composition appears to occur when DNA has increased by about one-third (No. 4 and 10 in Table 2); and yet another, with a high content of guanylic acid, when about one-half of the DNA has been replicated (No. 6 and 11 in Table 1 and No. 5 in Table 2). The ratio of 6-amino to 6-keto nucleotides[13] was near one in many of the specimens, with a mean of 0·97 for all 27 specimens.

The application of a pulse to a bacterial culture or to an organism raises many problems of interpretation with some of which a recent paper from this laboratory[11] has attempted to deal. The use of a narrowly spaced series of pulses administered to a synchronized cell population no doubt offers many advantages; but it remains that this grid, be it ever so fine, is imposed on, or made to slice through, the infinitely complex pulsations of a growing cell. We have probed along the time axis of a dynamic system—a synchronously dividing bacterial culture—and have obtained a set of values. How should they be interpreted and what is their bearing on present-day hypotheses concerning the transfer of biological information?

At the outset, one would wish to ask whether the analytical methods used in this article, as in all others dealing with this subject, in order to reveal the composition of the pulse-labelled RNA specimens, are really adequate; that is, whether regardless of the presumably varying specific activities of the nucleoside 5′-phosphates serving as the precursors of the polymers, the transfer of the phosphate groups to the (2′ + 3′)-positions, as it takes place in the course of the cleavage of RNA by alkali, does give rise to a randomization. This has been questioned repeatedly[11,13]. It may, however, be conceded that the technique is least objectionable when applied, as here, to the comparison of a series of samples produced under conditions having, ostensibly, only one variable, namely, time. Another point that should be emphasized is that, had a longer interval between samples than 10 min been chosen, a much simpler, but doubtlessly erroneous, picture could have emerged: the rapidly labelled RNA might have been in all cases only of the ribosomal type or only of the DNA type or mixed. It is the last-mentioned type that has, in fact, been encountered in investigations with non-synchronous bacterial populations[11,14–17]. If, on the other hand, an even finer net of pulse intervals could have been imposed—but this would be very difficult technically—it is quite conceivable that at one time or another a pulse-labelled RNA species of the composition of transfer RNA (compare Table 3) would have been found. It is quite clear that the examination of the composition or of other chemical and physical properties of an RNA specimen cannot be sufficient for a decision whether any of the many varieties of rapidly formed RNA observed in the course of a growth cycle conform with the concept[18] of messenger-RNA. There is, however, little question that the observation of a characteristic wave pattern in the synthesis and composition of RNA—a pattern apparently related to the extent of replication of DNA—is of some interest.

The alternations observed in this work possibly reflect a progressive transcription of the nucleotide sequence of the bacterial DNA in the form of a series of different pulse-labelled RNA molecules. Whether these, in turn, mirror the composition of individual cistrons in the DNA remains undetermined. The finding that the RNA newly made in the various cultures at identical levels of DNA replication is very similar in composition, but different from RNA produced at other levels of DNA increase, is consistent with the concept of an orderly transcription of the genome. The observation that the pulse-labelled specimens of RNA produced in different phases of synchronism vary in their composition is also in agreement with several previous investigations in which entirely different techniques (elution patterns[19], hybrid formation[20]) were used. Recent attempts to demonstrate the stepwise production of certain enzymes in synchronously dividing cells should also be mentioned in this context[21,22].

The work recorded here was carried out with one donor strain of *E. coli* (*HfrH*) with its given polarity of chromosome replication[1]. The outstanding shifts in the nucleotide distribution in the newly made RNA towards that expected for total or ribosomal RNA appeared referable to the periods when approximately 40 and 80 per cent of the DNA had been replicated. Does this now mean that at these times those nucleotide tracts on the DNA chain become available that are responsible for the formation of ribosomal RNA, and is this spacing characteristic of the particular strain of *E. coli* ? These and related questions, for example about the intervals during which the DNA-like RNA is produced, cannot yet be answered. But if the proposition is correct that different types of RNA are synthesized sequentially in a synchronized population, other donor strains of *E. coli Hfr* may exhibit another characteristic spacing. This problem is being investigated at present with strains having different chromosomal polarities.

This work was supported by research grants from the American Cancer Society and the National Institutes of Health, U.S. Public Health Service.

ION-EXCHANGE CHROMATOGRAPHY OF AMINO-ACIDS: IMPROVEMENTS IN THE SINGLE COLUMN SYSTEM

By Dr. A. R. THOMSON and B. J. MILES

Wantage Research Laboratory, Atomic Energy Research Establishment, Wantage, Berks.

PIEZ and Morris[1] have described a system for the quantitative analyses of amino-acids using a single column of ion-exchange resin, and instruments based on this principle are now commercially available (Phoenix Precision Instrument Co., Philadelphia, Penn.; Technicon Instrument Co., Ltd., Hanworth Lane, Chertsey, Surrey). With these the complete analysis and regeneration cycle take about 24 h. We wish to describe two sets of modifications in experimental conditions, the first giving a complete chromatogram in 15 h, the second in 5·5 h with no loss of resolution for the protein amino-acids.

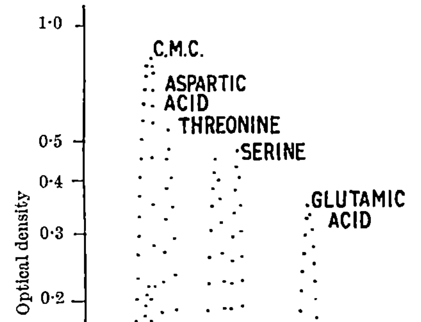

Fig. 1. Part of 15-h chromatogram. 0·2 μmoles each amino-acid, 0·5 μmoles *S*-carboxymethyl-cysteine (CMC)

(1) 15-*h chromatogram*. This may be effected as follows: (i) The flow of buffer to the column is increased to 47 ml./h. (ii) After regeneration with 0·2 N sodium hydroxide the column is equilibrated with 0·05 M sodium citrate (0·2 N with respect to Na^+) *p*H 2·9 in 10 per cent aqueous methanol. Methanol is required to maintain the resolution of threonine and serine and its use gives better separation of these amino-acids than is normally achieved with the 24 h chromatogram. 10 per cent methanol in the corresponding Varigrad buffer further improves threonine - serine resolution, but proline then tends to run into glutamic acid and the separation of cystine and methionine is impaired. (iii) Two additional chambers containing *p*H 5·0 sodium citrate are incorporated in the Varigrad to provide a safety margin for the overnight run. The other conditions are as for the 24-h chromatogram.

Temperature programming can also be used to improve threonine–serine resolution, but we have found this less convenient. Fig. 1 shows part of a typical chromatogram from carboxymethyl-cysteine to proline indicating the resolution obtained. The reproducibility of the system is unaffected by these changes.

(2) 5·5-*h chromatogram*. In investigations of protein structure, the rate of quantitative amino-acid analysis is often a limiting factor. Recently, details of a method

(Volumes for 4·5-h chromatogram in parentheses)

Chamber	0·05 M sodium citrate ($Na^+ = 0·2$ M)			pH 10·0	
	pH 2·75 in 10% methanol (ml.)	pH 2·90 (ml.)	pH 3·80 (ml.)	Na^+ 1·2 N (ml.)	(Na^+ 2·4 N) (ml.)
1	75 (75)	—			
2	– (60)	75 (15)			
3	– (10)	75 (65)			
4	—	5 (5)	70 (70)		
5	—	—	75 (75)		
6	—	—		75	(75)
7	—	—		75	(75)
8	—	—		75	(75)
9	—	—		75	(75)

enabling a complete analysis (application of sample to emergence of arginine), to be carried out in 4·5 h, have become available[2]. This is achieved by major modifications in the gradient, and by an increase in the flow of buffer to the column to 120 ml./h. However, the increased rate of analyses is only achieved at the expense of reproducibility (now ± 5 per cent), and, in our experience, by greatly impaired resolution of glutamic acid and proline, and of tyrosine and phenylalanine. Also, the use of pH 10 sodium citrate (2·4 N with respect to Na^+) leads to much packing of the column with a consequent marked rise in operating pressure (more than 600 lb./in.^{2}). This necessitates frequent repacking of the column and leads to rupture of the buffer transmission lines.

We now use the modified gradient given in Table 1. (The gradient for the 4·5 h chromatogram is shown in parentheses.) This gives improved resolution of glutamic acid and proline, and by using pH 10·0 buffer of lower ionic strength (1·2 N with respect to Na^+), packing of the column is kept to a minimum so that the pressure rise from an initial 400 lb./in.^{2} to 600 lb./in.^{2} is spread over about one month. With this system arginine emerges 5·5 h after loading of the column. Since regeneration can also be carried out at 120 ml./h, the use of a time switch readily enables two analyses to be carried out daily. A third analysis can be carried out with only 1–1·5 h evening work. Fig. 2 illustrates the resolution obtained with this system.

With this modified gradient, gradual packing of the column occurs, necessitating re-pouring, but only about once a month. However, because of the narrow particle size range of the resin (17 ± 2μ), 1–2 h settling followed by pumping for a few hours with starting buffer at 120 ml./h is adequate. Periodic topping-up of the column with resin is generally necessary.

Although the reproducibility of this latter system (± 5 per cent) is rather less than that of the 15-h chromatogram and the resolution is poor for many of the ninhydrin-positive components of interest in biological fluids such as blood plasma and urine, it is nevertheless quite adequate for the analysis of hydrolysates of most peptides.

The advantages of these modifications are:

(1) The 15-h chromatogram frees the auto-analyser during the normal working day for other analyses, without loss of resolution or reproducibility.

(2) With the 5·5-h system, 2–3 analyses/day can be carried out, with good resolution, without change in instrumentation and, since the equipment is operating for considerably less than 24 h/day, there is a distinct saving in costly reagents.

(3) When analysis of both protein and peptide hydrolysates is required the 15- and 5·5-h chromatograms can be run successively in 24 h, thus doubling the number of analyses possible yet retaining the greater reproducibility of the overnight run, for one of the analyses.

We thank S. J. Milsom for his assistance, and Dr. H. Holy, of Technicon Instrument Co., Ltd., for details of the 4·5-h chromatogram.

CROSSLINKING OF FIBROUS PROTEINS BY FORMALDEHYDE

By Dr. P. MASON and Dr. JUNE C. GRIFFITH

C.S.I.R.O. Wool Research Laboratories, Division of Textile Physics, Ryde, Sydney

THE reactions of formaldehyde with proteins have been investigated for many years and it seems now to be accepted, particularly following the work of Fraenkel Conrat *et al.*[1], that crosslinking between —NH_2 groups on side-chains of soluble proteins is produced by condensation reactions such as:

$$R\text{—}NH_2 + HCHO + H_2N\text{—}CO\text{—}R' \rightarrow R\text{—}NH\text{—}CH_2\text{—}NH\text{—}CO\text{—}R' + H_2O$$

Chemical techniques were used to identify the groups involved in the reaction (usually amino, amide or guanidino) but the conclusive evidence for intermolecular crosslinking was provided, in the case of soluble proteins, by measured increases in molecular weight brought about by treatment with formaldehyde[2]. Increases up to eight times were found in concentrated solutions of protein while no effect occurred in dilute solution. This emphasizes the need for the two appropriate groups of neighbouring chains to be brought into proximity before intermolecular crosslinking can take place.

Fibrous proteins, such as collagen and keratin, present a more complex situation because of their crystallinity and insolubility. A powerful chemical approach was used by Zahn[3], who showed that various bifunctional reagents crosslinked lysine and hydroxylysine residues in collagen; he identified the groups involved by hydrolysing the treated protein and identifying the newly formed pairs of crosslinked amino-acids. Zahn also applied this technique to silk and to wool, although again with reagents other than formaldehyde. For the system collagen–formaldehyde Gustavson[4] has demonstrated that the functional groups involved are the ε-amino groups of lysine.

Direct physical evidence of crosslinking in fibrous proteins has sometimes been sought by examining the effects on the force–extension relationships for fibres immersed in water; this procedure is not generally reliable, however, because the elastic properties are dominated by the crystalline fraction and small changes in crystallinity may easily outweigh the effects of crosslinking, as appears in the experiments reported here. The effects of formaldehyde on other physico-chemical properties of wool, such as 'supercontraction'[5], or swelling[6], have been shown to be consistent with the production of additional crosslinks although not unequivocally demonstrating that such crosslinking has occurred. In the case of collagen, however, the fact that formaldehyde insolubilizes gelatin gels gives an indication that intermolecular crosslinking may be possible in the parent collagen. Furthermore, by heating treated collagen fibres above their shrinkage temperatures they can be converted to the elastomeric state; the crystalline regions are melted, and stress–strain measurements can then be used to determine an average crosslink density for the specimen. This technique has been used successfully by Wiederhorn *et al.*[7,8], by Flory and Spurr[9] (with benzoquinone/collagen systems), and, recently, by Cater[10], who showed that aldehydes of greater molecular

——, Control; – – –, formaldehyde treated

size than formaldehyde, for example, acrolein, produced considerably greater crosslinking densities under comparable conditions in native collagen at 20° C. Cater's result emphasizes the importance of steric restrictions to crosslinking at potentially available sites in a fibrous protein.

In keratin the situation is further complicated by the presence of a high density of crosslinks (cystine residues) in the native state. However, the possibility of creating additional crosslinks has considerable theoretical and practical importance, and work now in progress has provided new evidence for the formation of intermolecular crosslinks in keratin by formaldehyde. As with collagen, one indication was given by the insolubilization of soluble derivatives from the protein and the other was obtained from equilibrium stress–strain measurements on fibres.

Two soluble wool proteins were obtained from Merino wool by reducing the disulphide bonds with alkaline potassium thioglycollate solution, alkylating the resulting thiol groups to prevent re-combination, and then fractionating into 'high-sulphur' and 'low-sulphur' components (*S*-carboxymethyl keratines) containing approximately 6 and 2 per cent of sulphur respectively. These fractions were kindly supplied by Dr. J. M. Gillespie of the C.S.I.R.O. Division of Protein Chemistry, Melbourne, who has described the fractionation procedures in detail elsewhere[11]. High-sulphur protein was dissolved in an equal weight of 36 per cent w/v aqueous formaldehyde and portions of the solution were heated at 52° C for periods up to 200 h. The low-sulphur protein was less easily dissolved, and the liquid content had to be increased about ten-fold by the addition of water to produce a homogeneous solution.

Gelation occurred in each specimen, and after the allotted time of heating the gels were washed and allowed to come to swelling equilibrium in water. They were then surface-dried and weighed and finally oven-dried at 105° C to constant weight. Fig. 1 shows how the proportion of the available protein which combined to form gel increased to a maximum and then decreased, presumably owing to degradation; control tests in which the proteins were heated in water produced less than 1 per cent of insoluble material. The gels were very dilute, with maximum weight fractions of protein of 0·08 for the high-sulphur and 0·03 for the low-sulphur component, and they could be dried and re-swollen by water. It may thus be concluded that formaldehyde produces intermolecular crosslinking in these two components of keratin.

To investigate crosslinking in the native, fibrous form, Corriedale wool fibres were heated for successive periods of 24 h in 36 per cent w/v aqueous formaldehyde solution at 52° C. Force-extension measurements were made on the fibres before starting the treatment and after each of the 24-h heating periods. These measurements were carried out at 20° C, at the constant extension rate of 10 per cent/min, and for extensions up to 15 per cent. Each test was made first in water and then in 98 per cent formic acid, which eliminates the elastic contribution from the crystalline material. After washing out the formic acid the length and elasticity of the fibre in water were substantially regained. The necessity of using such a method to eliminate the effects of crystallinity will be apparent from the results presented here.

Fig. 2 shows stress–strain curves obtained from tests in water on a formaldehyde-treated fibre and on a control fibre which had been subjected to the same experimental

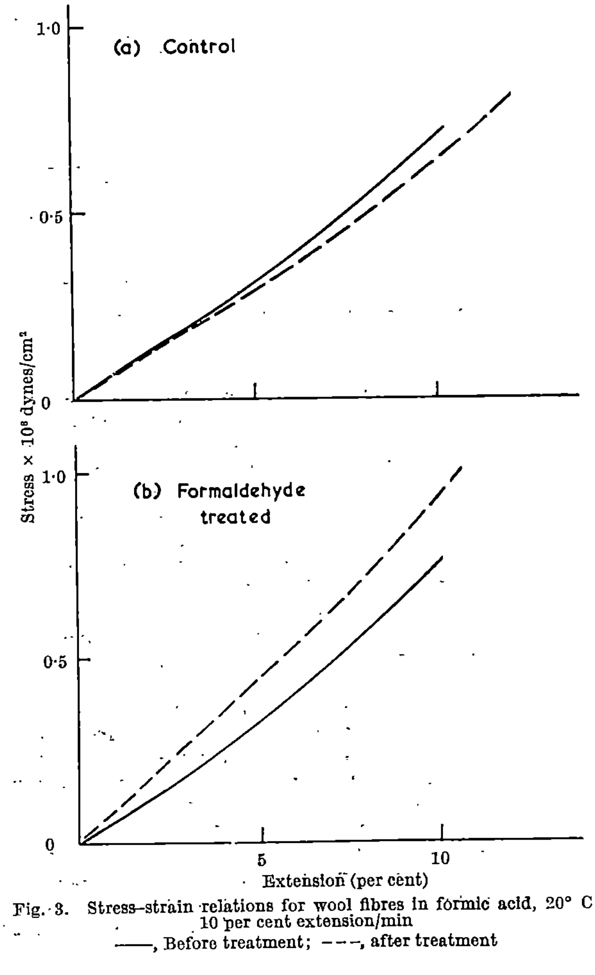

Fig. 3. Stress–strain relations for wool fibres in formic acid, 20° C; 10 per cent extension/min
——, Before treatment; – – –, after treatment

procedure, but with water substituted for the formaldehyde solution. The stresses are based on the cross-sectional area of the wet, unstrained fibre. Three features of these curves indicate structural alterations in the keratin, namely:

(1) The initial Young's modulus, that is, the slope of the linear 'Hookean' region between 0 and 2 per cent extension, is reduced to little more than half the control value by the formaldehyde treatment. The high elastic modulus in this region involves extension of the crystalline components, so that one action of the formaldehyde may be to produce a reduction in crystallinity.

(2) The modulus of the 'yield' region between about 2 and 15 per cent is approximately doubled. Under the present test conditions this modulus is very dependent on the rate of extension; the observed effect could therefore be due either to increased crosslinking or to an increase in the internal viscosity or to both of these factors.

(3) The extent of the yield region is considerably reduced by the formaldehyde treatment. Thus taking as a criterion the extension at the point Y where the stress has increased by 10 per cent above the level indicated by extrapolation of the yield region, the formaldehyde treatment produces a significant reduction from 28·6 to 24·3 per cent. According to the view of the molecular structure of wool developed by Feughelman[12] this effect indicates an increase in crosslinking in the less highly crosslinked parts of the amorphous matrix.

Only the last of these three effects thus gives a direct indication of crosslinking and even this necessitates an appeal to a particular model of fibre structure. A comparison of the curves up to about 15 per cent extension would, in fact, suggest that no crosslinking had taken place but only some degradation of the fibre.

In contrast to the tests in water the tests in formic acid gave positive evidence of crosslinking. Fig. 3 shows typical stress–strain data in which the initial modulus is about 7×10^8 dynes/cm^2, that is, about one-twentieth of the value measured in water. There is evidently no direct contribution from organized crystallites and the material shows a rubber-like elasticity. Furthermore, very little stress-relaxation was found under the test conditions so that the curves may be taken as equilibrium values and their slopes used as measures of an effective degree of crosslinking. It is apparent that the formaldehyde causes a stiffening of the fibre under conditions where the control fibre is slightly softened. There is thus an increase in crosslinking density, produced by the formaldehyde treatment, which amounts in magnitude very approximately to 40 per cent of the crosslink density in the native wool.

Finally, it may be observed that the sharp decrease in Young's modulus produced by formaldehyde occurs during the first 24 h treatment; thereafter the modulus decreases slowly at the same rate as for the control fibres. Reference to Fig. 1 suggests that the sharp decrease is brought about by reaction between the formaldehyde and the low-sulphur protein in the wool, in keeping with the concept that the low-sulphur protein may be identified with the oriented crystalline components of the fibre. This is qualitatively in agreement with the observation by Richards and Speakman[5] that increasing degrees of formaldehyde treatment progressively lowered the supers contraction obtainable in wool fibres under standard conditions.

DEOXYRIBONUCLEIC ACID AND THE MOLECULAR BASIS OF SELF-DUPLICATION

By Prof. BARRY COMMONER

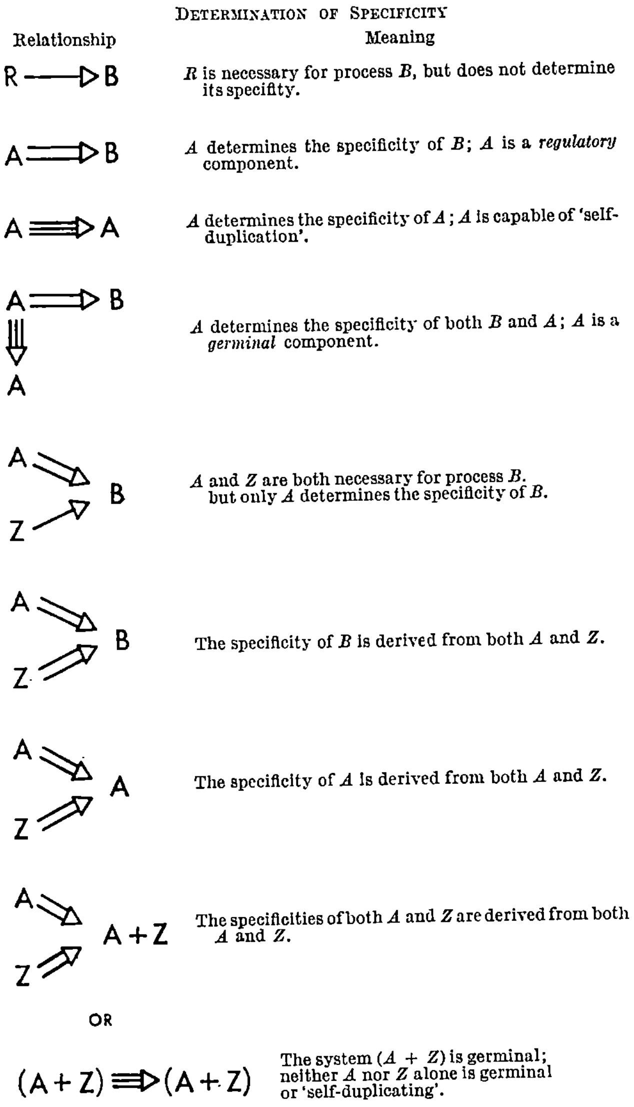
Henry Shaw School of Botany and the Adolphus Busch III Laboratory of Molecular Biology, Washington University, St. Louis, Missouri

INVESTIGATIONS of the biochemical processes mediated by nucleic acids have led to the generalization that deoxyribonucleic acid (DNA) is capable of self-duplication, and represents a 'code' which specifies the inherited characteristics of the organism[1-4]. The importance of such a conclusion is self-evident, for it would reduce to a molecular level the unique capabilities of living matter for self-perpetuation and inheritance. It is of interest, therefore, to determine what criteria are required to establish that a molecule, such as DNA, is capable of self-duplication and control of inheritance, and to examine the degree to which the available evidence meets such criteria.

Self-duplication is a concept of biological origin regarding the source of inherited specificity in the replication of living organisms. A typical self-duplicating biological system consists of a specific cell and environmental constituents, such as water, oxygen and nutrients, which are essential to the growth and division of the cell. The concept of self-duplication holds that among such a system's several necessary constituents, only one, the cell, is the source of inherited specificity which appears in the product of the replicative event. Thus, in determining whether a system is capable of self-duplication, the chief issue is the source of the biological specificity which is transmitted to the progeny of the replicative event.

In some instances it is possible to analyse inheritable biological specificity in molecular terms, since a number of genetic effects are known to influence particular molecular structures or biochemical processes. Such biochemical specificity is represented by the particular order of the residues which comprise linear polymers such as nucleic acids and proteins, or by a particular path of metabolic reactions in the cell. In biological polymers a very large number of primary structures (that is, sequences of residues) have equal thermodynamic probability, and the specificity of a given molecule represents the choice of a particular sequence among the many possible ones. The numerous molecular components of the cell are thermodynamically capable of a very large number of reactions, and the specification of a given reaction pathway represents the activation of relatively few reactions among the numerous possible ones.

Both types of biochemical specificity are achieved by regulation of the rates of chemical reactions. In keeping with terminology introduced earlier[5], a component, or



R is necessary for process *B*, but does not determine its specifity.

A determines the specificity of *B*; *A* is a *regulatory* component.

A determines the specificity of *A*; *A* is capable of 'self-duplication'.

A determines the specificity of both *B* and *A*; *A* is a *germinal* component.

A and *Z* are both necessary for process *B*, but only *A* determines the specificity of *B*.

The specificity of *B* is derived from both *A* and *Z*.

The specificity of *A* is derived from both *A* and *Z*.

The specificities of both *A* and *Z* are derived from both *A* and *Z*.

The system (*A* + *Z*) is germinal; neither *A* nor *Z* alone is germinal or 'self-duplicating'.

Fig. 1. Diagram to summarize definitions of symbols for non-regulatory participants, regulatory and germinal components of systems involving transfer of biochemical specificity

system, which is capable of determining the specificity of a particular cellular reaction will be termed a regulatory component or system, and its participation in the chemistry of the cell indicated by the symbol (═══▷). A regulatory component or system which also serves as the sole determinant of the specificity of its own synthesis is self-duplicated, and, if transmissible, may serve as an agent of inheritance. An agent with these properties will be termed a germinal component or system, and its participation indicated by the symbol (≡≡≡▷). The participation of a component or system that is essential to a process in which transfer of specificity occurs, but which nevertheless does not contribute any specificity to it, will be indicated by the symbol (———▷).

The foregoing relationships, which are summarized in Fig. 1, permit an analysis of the manner in which a molecular system participates in a replicative or regulatory event. As indicated in Fig. 1, a molecule or system of molecules is to be considered capable of self-duplication only when it can be shown to be germinal, that is, if all the specificity embodied in the new molecule is derived from the parental one. Applied to a typical cellular self-duplicating system, the foregoing designations would show that: parent cell ≡≡≡▷ new cell; nutrients, etc. ———▷ new cell. Since, of the components necessary for the production of a new cell, the parent cell is alone capable of determining the new cell's specificity, the parent cell is a germinal component and: parent cell ≡≡≡▷ new cell.

The theory of the DNA code proposes that DNA governs biological inheritance because the specificity of its molecular structure—the sequence of nucleotides in a particular segment of DNA—is the sole source of both the specificity of further DNA synthesis[1], and of the specificity of a particular inherited metabolic reaction in the cell[2-4]. The theory proposes the stepwise transfer of the specificity embodied in the nucleotide sequence of the DNA to the amino-acid sequence of a particular protein enzyme, which thereby determines the enzyme's biochemical specificity and establishes a metabolic pathway in the cell. The relevant molecular processes are now well known and need not be described here.

For the purposes of this discussion, it will be assumed that: (1) the overall transfer of specificity from DNA to protein and from DNA to DNA that is proposed by the DNA code theory is in fact operative; (2) the governing molecular mechanisms are not necessarily those proposed by the theory; (3) the system is not necessarily the only mechanism which determines inheritance of the biochemical specificity of the cell. These assumptions will simplify further considerations without affecting their result; it will be shown later that these assumptions are in fact the best approximation of what is actually known.

The scheme proposed by the theory of the DNA code is summarized in Fig. 2*A*, using the symbols defined earlier. The scheme leads to the notion that DNA is a 'self-duplicating molecule' because it holds that DNA is the only source of the specificity of newly synthesized DNA. This conclusion is, however, valid only if it can be shown that no other regulatory components participate in DNA synthesis. It becomes important, therefore, that the experimental evidence be scrutinized with this question in mind.

Experiments on the synthesis of DNA *in vitro* show that three classes of components participate: the DNA primer or 'template', the necessary enzyme (that is, DNA polymerase), and the requisite deoxynucleotides. Kornberg's investigations of the DNA polymerase system, which synthesizes DNA from triphosphodeoxynucleotides, usually in the presence of primer DNA, yield evidence that the nucleotide sequence of the DNA product is influenced in a complementary manner by the nucleotide sequence of the primer[1,6]. This shows that some transfer of specificity from primer to product occurs, and that the primer serves as a regulatory component in the determination of the molecular specificity of the DNA product. However, although the theory requires an exact correspondence between the frequencies of a nucleotide in the primer and of the complementary nucleotide in the product, recent experiments show that this condition is sometimes not observed with respect to deoxyadenylic and deoxythymidylic acids[7]. Moreover, if precise replication occurs in the DNA polymerase system it should be possible to demonstrate that DNA newly synthesized in the presence of a biologically active primer is itself active. However, this phenomenon has not yet been conclusively demonstrated[8]. There is, therefore, no direct evidence that the nucleotide sequence of the primer exerts the total control of the nucleotide sequence of the product that the theory requires.

A conclusion that DNA is a self-duplicating germinal component also calls for the negative demonstration that the DNA polymerase enzyme, which is an obligate participant in DNA synthesis, does not contribute to the biochemical specificity of the product (that is, to its nucleotide sequence). However, certain experiments with the DNA polymerase system, reported by Kornberg *et al.*, lead to the empirical conclusion that the enzyme does, in fact, contribute specificity to the DNA product[9].

In the presence of a mixture of deoxyadenylic and deoxythymidilic acids—and in the absence of a DNA primer—the polymerase causes the formation (after a lag

Fig. 2. (*A*) Illustrates the transfer of biochemical specificity in the system proposed by the theory of the DNA code, which holds that the biochemical specificity of DNA (its nucleotide sequence) is the sole source of specificity in the replication of DNA and in the synthesis of protein, the specificity of the latter determining a particular inherited metabolic pathway. In this scheme DNA is itself a germinal self-duplicating component and the sole source of the cell's inherited biochemical pattern. (*B*) Illustrates modification of the system suggested by the evidence discussed in the text. This scheme illustrates the consequences of evidence that part of the biochemical specificity of DNA originates in the polymerase enzyme which catalyses DNA synthesis, and possibly in the relative availability of the several requisite nucleotides. Also shown is the effect of contribution of specificity originating in amino-acyl RNA synthetase, an enzyme essential to protein synthesis. In this scheme, DNA is neither a germinal, self-duplicating component, nor the exclusive determinant of the cell's biochemical specificity. Instead, these effects have a multi-molecular origin and the entire system requires pre-existing specificity in both DNA and at least 2 protein enzymes. Symbols according to definitions given in Fig. 1

period) of an *A–T* copolymer, with a regular alternating order of nucleotides, ... *ATATAT* .... In the absence of primer DNA the polymers .... *GGG* .... and .... *CCC* .... are formed when *G* or *C* are present alone; only these polymers are formed in the presence of a *G* + *C* mixture. Each of the polynucleotide products synthesized in the absence of DNA primer has a simple but definitely non-random nucleotide sequence and therefore possesses biochemical specificity (or in the parlance of DNA code theory, 'genetic information'). This specificity does not arise in the nucleotide sequence of a primer DNA molecule, for none is present in the reaction. The source of the product's specificity appears to be the enzyme, which is therefore—along with the DNA primer —a regulatory component in the system which synthesizes DNA. In the absence of a primer the DNA polymerase enzyme system appears preferentially to catalyse the formation of certain specific internucleotide bonds, ... *A–T*, ... *T–A*, ... *G–G*, ... *C–C*; it fails to catalyse the formation of certain other bonds, ... *A–A*, ... *T–T*, ... *G–C*, ... *C–G*.

These results indicate that in a system which synthesizes DNA in the presence of both primer and enzyme, both these constituents may be expected to contribute to the specificity of the DNA product. Direct evidence of the dual origin of DNA specificity in such a system requires observation of the effects of experimental variation of the specificity of the two components on the nucleotide sequence of the DNA product. While the absence of the necessary techniques precludes complete data on DNA nucleotide sequence, evidence regarding overall nucleotide composition, the variation of which must reflect gross changes in nucleotide sequence, is available. Lehman *et al.*[10] have reported the nucleotide composition of DNA produced when primers derived from several different biological sources are added to a system based on polymerase from *E. coli*. When both the DNA primer and the polymerase are derived from *E. coli*, the primer and the product differ only very slightly in base composition. Thus, if either total *E. coli* DNA, or DNA from the *E. coli*-specific *T*2 bacteriophage, is used as primer in the *E. coli* polymerase system, the *A* + *T*/*G* + *C* ratio (which is the most sensitive overall index of nucleotide composition) of the product differs from that of the primer only by 5 and 1 per cent, respectively. When DNA primers from other organisms are used, the *A* + *T*/*G* + *C* ratios of the products resemble those of the primers, although the latter are different from that of the *E. coli* DNA by a factor of 2. However, the agreement is by no means exact. When the primer is derived from *M. phlei*, the *A* + *T*/*C* + *G* ratios of primer and product differ by 20 per cent of the primer value; with *A. aerogenes* primer, the difference is 25 per cent; with calf thymus primer the difference is 17 per cent. Thus, when both primer and enzyme are derived from the same biological source (*E. coli*), the *A* + *T*/*G* + *C* ratios of product and primer agree to within 5 per cent; but when the two components are derived from separate species, considerably larger differences are observed. This is evidence that the relatively precise replication of the primer which occurs in the homologous system depends on both the specificity of the DNA primer, and on the specificity of the DNA polymerase enzyme, at least in so far as such specificity is reflected in the $A + T/G + C$ ratio. The influence of the polymerase specificity on DNA nucleotide composition appears to be smaller than that due to the primer, but it is, nevertheless, appreciable.

The evidence of biochemical genetics suggests that DNA nucleotide sequence is probably replicated within a given organism with a high degree of precision. The foregoing *in vitro* evidence indicates that the precision of replication in the living system is dependent, at the least, on specificity contributed by both the DNA primer and the species-specific polymerase which catalyses DNA synthesis.

Evidence regarding the effect of relative concentrations of nucleotides that are essential for DNA synthesis on DNA nucleotide sequence (and therefore on its biochemical specificity) is rather scanty. Base ratios of extracted DNA do not appear to change significantly when normal micro-organisms are grown in different types of nutrient media. On the other hand, Kanazir[11] observed that when bacterial mutants incapable of thymine synthesis are transferred to a thymine-deficient medium, the rate of mutation (that is, of reversion to thymine dependence) increases sharply among the cells produced just before thymineless death occurs. This observation, which has since been confirmed[12], suggests that thymine deficiency that is so severe as to be nearly lethal may alter the nucleotide sequence of DNA, which according to substantial evidence is the basis of such mutations.

The relevant *in vitro* evidence appears to be a single experiment in which enzymatic DNA synthesis with the four requisite nucleotides present in equimolar concentrations was compared with systems in which either deoxythymidilic acid or this nucleotide and deoxyadenylic acid were reduced five-fold in concentration[10]. No significant changes in the ratios of $A + T/G + C$ or $A + G/C + T$ in the synthesized DNA were observed. In view of the relatively limited variation in nucleotide concentration this observation is not conclusive evidence that nucleotide sequence is wholly independent of nucleotide availability during DNA synthesis.

The heterocatalytic regulatory effects of DNA, that is, the transfer of specificity from DNA to protein, have been the subject of a considerable number of recent investigations. Most of these results have been interpreted as lending support to the scheme shown in Fig. 2*A*. However, the available data fail to support the conclusion that the transfer of specificity between DNA and protein is rigorously determined by the specificity of the 'messenger' RNA (which, according to the theory, is itself derived from DNA nucleotide sequence).

Of particular importance is the origin of specificity in the system which provides the 'code' relating nucleotide sequence to protein amino-acid sequence. According to the conventional theory, the nucleotide sequence of a DNA segment (which represents a genetic agent) determines the nucleotide sequence of a 'messenger' RNA (*m*RNA). The latter, in turn, mediates the order of assembly of short segments of 'transfer' RNA (*t*RNA), previously charged with the appropriate amino-acids, on the ribosome where the amino-acids are joined to form the protein's primary structure. The addition of a specific amino-acid to the terminus of a particular *t*RNA is catalysed by an enzyme, amino-acyl RNA synthetase. According to the conventional theory, the ordering of the amino-acid sequence in the protein is determined by the nucleotide sequence of the *m*RNA, a given nucleotide pattern in the latter having an affinity for a particular one of the 20-odd *t*RNA's, thereby achieving the appropriate positioning of the amino-acid uniquely associated with a given *t*RNA unit. The theory of the DNA code requires that, of the several components of the system which participate in the assembly of the protein's amino-acid sequence, only the messenger serves as a source of protein specificity (that is, its amino-acid sequence). If any other source of specificity were to intervene, then the basic conclusion of the 'code' theory, that protein specificity (and therefore metabolic control of the cell) is wholly determined by DNA nucleotide sequence, fails. It is appropriate, therefore, to consider the available evidence regarding the origins of the specificity which regulates the ordering of amino-acid sequence in protein synthesis.

A crucial test of this question has recently been reported by Barnett and Jacobson[13], who examined the influence of synthetases derived from two different species on the specificity of amino-acid attachment to particular *t*RNA's isolated from one of them. They find that soluble RNA from *E. coli* contains only a single *t*RNA component which is charged specifically with phenylalanine by the action of *E. coli* synthetase. However, when the synthetase is derived from *N. crassa*, three separable *t*RNA units found in soluble *E. coli* RNA become charged with phenylalanine: (*a*) One *E. coli* fraction, apparently identical with the component that is specifically charged with phenylalanine by the *E. coli* enzyme, exhibits the same property when *N. crassa* synthetase is present. (*b*) A second *E. coli* RNA fraction is charged with either phenylalanine or alanine by the *N. crassa* synthetase, but is not affected by the *E. coli* enzyme. (*c*) A third *E. coli* RNA fraction is charged with phenylalanine by the *N. crassa* enzyme, but it not acted on by the comparable *E. coli* enzyme. The authors regard these observations as evidence for "interspecies degeneracy, ambiguity, and lack of universality in this coding system". In effect, these results show that the precision with which an intact *E. coli* cell is capable of regulating the specificity of the proteins which it synthesizes depends not only on the specificity provided by the DNA genetic agent (presumably transmitted by *m*RNA), but also on the species-specificity of its amino-acyl RNA synthetase. There is considerable evidence in the literature which shows that *in vitro* protein synthesis involving components derived from different species fails to produce protein with the specificity expected from the source of the *m*RNA[14].

Similar questions arise regarding the participation of transfer RNA's and of ribosomes in the determination of amino-acid sequence in protein synthesis. While the available results are not definitive, there is no strong evidence against the conclusion that these agents, like the synthetase, may contribute to the specificity of protein synthesis[15].

Observations that a single gene mutation may give rise to a single change in a protein's amino-acid sequence are sometimes cited in support of the conclusion that protein amino-acid sequence is rigorously specified by DNA nucleotide sequence. However, these effects are exhibited only by entire living systems. The only rigorous conclusion that may be derived from them is that DNA specificity does exert a precise regulatory effect on amino-acid sequence, provided that protein synthesis takes place in a cell of appropriate specificity. However, it is evident from the above that the species-specificity of non-DNA constituents of a cell is essential for precise determination of protein structure. Hence, data regarding genetic effects on amino-acid sequence do not militate against the conclusion that non-DNA constituents of the cell participate in the determination of protein specificity.

To sum up, the present evidence concerning the reactions involved in the development of the specificity finally embodied in DNA and in proteins indicates that such specificity can arise, in part, from sources other than DNA nucleotide sequence. While complete support for this conclusion must await detailed analysis of the actual reaction mechanisms which govern the formation of the covalent inter-residue bonds in DNA and of the several successive reactions involved in protein synthesis, the evidence now available shows that at least two of the relevant enzymes possess species-specificity which can influence the ordering of residues in both DNA and proteins.

These considerations suggest certain amendments to the system of regulatory effects proposed by the theory of the DNA code[16]. Fig. 2*B* shows how the additional sources of biochemical specificity indicated by the evidence brought forward here affect the conventional system. DNA specificity is no longer self-determined, but depends on DNA nucleotide sequence and on the specificity of the polymerase (and perhaps on the relative concentrations of free nucleotides as well). Similarly, the specificity of a protein is determined not only by DNA nucleotide sequence (transmitted via 'messenger' RNA), but also by the species-specificity of the synthetase (and possibly by specificities of the 'transfer' RNA's and of ribosomes).

Accordingly, the systems which govern both the specificity of protein synthesis and of DNA synthesis are fundamentally circular in nature. Although protein specificity is derived, in part, from DNA specificity, the latter is, in turn, partially dependent on the protein specificity of the DNA polymerase, which is itself dependent on the specificity of at least one other protein, the amino-acyl RNA synthetase. The system is operative as a self-sufficient source of specificity for DNA and for proteins only if DNA with a specific nucleotide sequence, and at least two proteins which possess species-specificity (polymerase and synthetase), are already present. This situation prevails in the intact cell. It can apparently be imitated with varying degrees of success in *in vitro* systems which derive all the necessary components from the same biological source, and thereby retain the complex sources of specificity which are present in the living cells of a given species.

As indicated by a comparison of Figs. 2*A* and *B*, the net effect of the introduction of these additional sources of biochemical specificity is to negate the simple conclusion that DNA is by itself a germinal, self-duplicating component or that DNA is the sole source of the biochemical specificity, embodied in proteins, that regulates the specificity of cellular metabolic processes. Such a conclusion is valid only if the specificity-transferring system is monophyletic, proceeding linearly from DNA to protein without branches or feedback. But the available evidence negates this conclusion; specificity ultimately embodied in DNA nucleotide sequence and in protein amino-acid sequence has a multi-molecular origin in a system which is characterized by circular feed-back relations.

A number of experiments show that the introduction of certain DNA components, such as bacterial transforming principle, into an appropriate host cell, can induce in the latter the appearance of a new operational genetic agent. This result does not conflict with the foregoing conclusion that DNA replication and its regulatory effect on the cell require sources of specificity other than DNA. A given DNA transforming agent is effective only when introduced into a living cell of an appropriate type. Hence, replication of the agent may depend on specificity contributed by the host cell. Moreover, quite massive changes in the nucleotide composition of bacterial DNA (for example, the replacement of 50 per cent of *E. coli* DNA thymine with 5 bromouracil) lead to an increased incidence of normally observed mutations, but do not cause gross changes in the range of mutations or in the species characteristic of the cell[17]. If the total genetic specificity were under the exclusive control of the DNA nucleotide sequence, such a massive change in DNA composition would be expected to disorganize severely the main features of the organism. On the other hand, if 5 bromouracil is regarded as a biologically effective substitute for thymine in the DNA nucleotide sequence, then no massive effects would be expected. However, in this case there is no explanation for the bromouracil-induced increase in mutation rate.

If the view summarized in Fig. 2*B* is correct, and agents such as DNA polymerase or amino-acyl RNA synthetase are, like DNA itself, regulatory components and therefore sources of specificity in DNA replication or in protein synthesis, why is there no evidence that such proteins are capable of acting as transferable genetic agents ? The following considerations suggest that this empirical observation may be due to a secondary difference between the status of DNA and the related enzymes in the cell, rather than to any basic difference in their capabilities as regulators of biochemical specificity.

The evidence of genetics shows that DNA agents which are the basis of typical Mendelian effects are present in the cell in only one or two replicas; that is, they are non-redundant. Hence, an invading DNA agent, such as transforming DNA, can readily compete with the DNA-borne genetic agents pre-existing in the host cell, or failing that, appear in an appropriate proportion of subsequent daughter cells unaccompanied by the indigenous agents. Thus, the striking genetic effect of an invading DNA agent is due not only to its regulatory capability, but also to the low level of multiplicity of the cell's normal DNA-borne genetic agents with which it must interact.

However, in the case of enzymes such as DNA polymerase, or amino-acyl RNA synthetase, matters are very different, for a single cell may contain hundreds or more of separate enzyme molecules. For this reason an invading enzyme molecule, even if capable of contributing to the specificity of DNA and protein synthesis, is not likely to have a noticeable effect on the biosynthetic activity of the host cell and little chance of becoming segregated out as a dominant form in the enzyme population of any daughter cells. Hence, no genetic effects are ordinarily discernible. Nevertheless, such an observation does not prove that such proteins are incapable of contributing to the specificity of DNA or protein synthesis.

Conclusions. The foregoing considerations lead to the conclusion that the role of DNA in biological inheritance does not reflect a unique capability for self-duplication and for regulation of the specificity of protein synthesis. While DNA does contribute to the specificity of DNA and of protein, this property is shared with certain protein agents, for example, DNA polymerase and amino-acyl RNA synthetase. The special role of DNA as a vehicle for the Mendelian gene is indeed based on a unique attribute of 'template' DNA. However, DNA is not unique because it is capable of regulating biochemical specificity, but because, among the cell's regulatory agents, those composed of DNA occur at a very low level of redundancy.

These conclusions suggest certain theoretical and operational consequences. With regard to the general theory of molecular control of inheritance, they propose that the source of transmissible biochemical specificity in inheritance is multi-molecular, rather than being derived uniquely from the specificity of DNA. In particular, the assumption described in the so-called "Central Dogma" (which states that biochemical specificity can be transferred from nucleic acid to nucleic acid, and from nucleic acid to protein, but not from protein to nucleic acid[3]) is denied by the available evidence. Hence, the general consequence of this assumption—that the capability of the living cell for self-duplication and inheritance is uniquely determined by DNA—is not valid. The precise replication of DNA and proteins in living cells requires the pre-existence of both specific DNA and specific cytoplasmic proteins. Hence the capability of living matter for precise self-duplication is derived not only from nuclear material, but from the cytoplasm as well. This is a restatement of a conclusion long familiar to biologists—that life, in its present specifically replicative form, is derived from pre-existing life. Considerations which have been published elsewhere also show, on other grounds, that the 'template' function of DNA is only a special case of a more general and primitive DNA function, nucleotide sequestration, and suggest that early forms of life lacked the precise type of replication observed in present living things[5].

The position developed in this article also leads to two chief operational conclusions which may be subject to experimental test. If the code theory were correct, then it should be possible, by chemical modification of DNA, to develop specific nucleotide sequences hitherto absent from living things; and, in transformation experiments, to achieve wholly new inheritable biological characteristics and even new forms of organisms. In contrast, the view that inheritance is based on multi-molecular sources predicts severe limits on the biological effectiveness of artificial modifications of DNA nucleotide sequence. Such gross changes are likely to be incompatible with the specificity requirements imposed by enzymes, such as DNA polymerase and amino-acyl RNA synthetase, which would remain unchanged in a DNA-mediated transformation experiment. Hence, an artificially modified DNA might, when introduced into an appropriate cell, induce the synthesis of new DNA; but, because of the specificity contributed by the cell's enzymes, the artificial DNA would not be exactly replicated, the product being a polynucleotide more closely resembling normal DNA. For the same reason, this view predicts that in such experiments the resultant biological mutations will not depart appreciably from the range and type of mutations observed in the normal biology of the organism. These contrasting views of the consequences of extensive chemical modification of DNA should be subject to experimental test.

The theory of the DNA code holds that only DNA, or possibly an RNA component on which DNA specificity is impressed, can serve as a molecular vehicle for the transmission of inheritance. In contrast, if the view developed in this article is correct, it should be possible to demonstrate genetic transformation of a cell by a protein agent, analogous to the known instances of bacterial transformation by DNA. Such an experiment would require the introduction of an enzyme which is capable of imparting specificity in DNA or protein synthesis into an appropriate host cell under conditions in which the natural redundancy of these agents in the cell is sufficiently reduced to permit the expression of the invading protein. Experimental methods for accomplishing the low levels of protein redundancy essential for such an investigation might include suppression of protein synthesis in the host by means of inhibitors or by substrate starvation, or the use of micro-organisms of extremely small cell size, in which cytoplasmic redundancy might be correspondingly reduced[18]. I thank Prof. M. Swann, of the Zoology Department, University of Edinburgh, for the last suggestion.

As I have pointed out elsewhere[16], the assumption (derived from biochemical evidence) that the unique capability of living matter for self-duplication is due to the presence within it of a molecule, DNA, which itself has this attribute, conflicts with certain principles of biology, especially the cell theory and the epigenetic basis of development. The considerations developed in this article may help to elucidate this discrepancy, for they suggest, from an analysis of the biochemical data themselves, that the operative unit of self-duplication is not DNA, but a multi-molecular system which is so complex as to require the participation of the entire living cell.

ACTIVITY OF THE HEXOSE MONOPHOSPHATE SHUNT IN THE NORMAL AND DYSTROPHIC RETINA

By Dr. H. W. READING

Medical Research Council Wernher Group for Research in Ophthalmological Genetics, Royal College of Surgeons of England,
Lincoln's Inn Fields, London, W.C.2

THE patterns of glucose catabolism via the Embden–Meyerhof and Krebs cycle pathways have been compared in developing normal and dystrophic rat retinæ[1]. The dystrophic animals have a recessively inherited degenerative condition of the retina resembling human retinitis pigmentosa. No qualitative differences between normal and dystrophic retinæ were found and the quantitative differences which could be detected were subsequent to histological degeneration.

The hexose monophosphate (HMP) shunt pathway of glucose catabolism has been implicated in the normal functioning of the visual cycle in the mammalian retina[2]. It appears that, after bleaching, reduction of retinene to vitamin A alcohol is coupled to the oxidation of glucose via the HMP shunt mechanism through the utilization of $NADPH_2$. In addition, Cohen and Noell[3] reported relatively high activities for the HMP shunt in the young, undeveloped rabbit retina.

In the investigation described here, the activity of the HMP shunt was examined in developing normal and dystrophic rat retinæ over the age range 6–28 days. This period covers the development of the lesion in the abnormal retina. The experiments were carried out *in vitro* on retinal tissue obtained from normal, black-hooded (*PVG*) rats and pink-eyed piebald agouti rats affected with the retinal dystrophy[4].

All experiments were carried out on litter-mates irrespective of sex. Preparation of retinæ for biochemical investigation has been previously described[1]. 25 mg quantities of tissue were incubated for 1 h at 37° in 1 ml. Krebs–Ringer bicarbonate medium[5] in an atmosphere of 95 per cent oxygen–5 per cent carbon dioxide, in special

Table 1. RESULTS EXPRESSED AS THE RATIOS OF ACTUAL YIELDS OF $^{14}CO_2$ FROM 1-^{14}C GLUCOSE/6-^{14}C GLUCOSE

Age	Normal	Dystrophic	Increase in dystrophic (%)	
6–7 days	3·5 (0·4)	3·3 (0·6)	−6	$P = 0·8 - 0·7$
14 days	1·6 (0·4)	2·4 (0·5)	50	$P = 0·3 - 0·2$
27–28 days	1·5 (0·2)	2·4 (0·2)	56	$P = 0·01$

(*S.E.M.*, in brackets)

Table 2. RESULTS EXPRESSED AS RATIOS OF SPECIFIC YIELDS OF $^{14}CO_2$ FROM 1-^{14}C GLUCOSE/6-^{14}C GLUCOSE

Age	Normal	Dystrophic	Increase in dysotrophic (%)	
6–7 days	2·9 (0·6)	4·1 (0·8)	41	$P = 0·3 - 0·2$
14 days	1·7 (0·3)	2·5 (0·5)	49	$P = 0·2 - 0·1$
27–28 days	1·2 (0·1)	1·8 (0·2)	50	$P = 0·05 - 0·02$

(*S.E.M.*, in brackets)

micro-Warburg flasks fitted with two side-arms, one of which was closed with a rubber cap. 2 μc. of either 1-^{14}C glucose or 6-^{14}C glucose diluted with inert carrier glucose to give a final concentration of 0·1 per cent in the medium was added from the side-arm to initiate the reaction. Carbon dioxide was collected at the end of the incubation period by injecting alkali on to the paper in the centre well, followed immediately by injection of acid into the medium, with 10 min additional incubation to ensure complete collection. Medium and tissues were separated by centrifuging and the tissues washed twice in isotonic saline, the washings and medium being pooled and finally made up to constant volume. Radioactive carbon dioxide was precipitated as barium carbonate, plated out on aluminium planchets and counted under a thin end-window Geiger–Müller counter, suitable corrections being made for self-absorption. Aliquots of medium before and after incubation were chromatographed on Whatman No. 1 paper in a solvent system of *tert*-butanol, 80 ml.–picric acid, 4·0 g–water, 20 ml. The radioactivity of the glucose 'spots' was evaluated by running the chromatograms through an automatic scanning device[6].

Evaluation of the relative activity of the HMP shunt pathway in the catabolism of glucose was carried out in two ways; (*a*) by determination of the actual yield of carbon-14 recovered as respiratory carbon dioxide and expressed as the ratio of $^{14}CO_2$ yield from 1-^{14}C glucose to that from 6-^{14}C glucose (Table 1); (*b*) by expressing the $^{14}CO_2$ yields (called specific yields) in terms of glucose utilized (Table 2). The latter method is based on those of Wang *et al.*[7], modified by determining residual glucose after incubation as suggested by Katz and Wood[8]. This overcomes possible criticism of the assumption that the same amounts of differently labelled glucose are utilized in parallel experiments. In all cases, the activities of the carbon dioxide collected were calculated to conform to a constant specific activity of glucose substrate, the latter being determined from aliquots of medium before incubation.

The results clearly show an elevation in the activity of the HMP shunt pathway in the dystrophic retina compared with the normal at corresponding ages. The differences, however, are greater during the later stages of development of the lesion, that is, at 14 and 28 days, and both methods of assessing the results show higher statistical significance at these times. It is, however, noteworthy that results taking glucose utilization into account (based on specific yields) show higher significance throughout. The results also demonstrate conclusively the decline in relative importance of the shunt pathway for glucose breakdown, with increase in age and development, in the normal retina.

The existence of a primary biochemical lesion associated with the genetical anomaly in this degenerative retinal condition has been sought for some time. Recently, Reading and Sorsby[9] reported an early depression in rate of protein synthesis confined to the retina in affected rats, occurring some 6–8 days before histological changes. This depression becomes less marked as development proceeds, until, at 24 days of age, rates of protein biosynthesis in normal and dystrophic retinæ are indistinguishable. Depression in synthesis of a specific protein moiety is a phenomenon associated with a number of other genetic abnormalities, especially those concerned with hæmoglobin synthesis[10].

Chronologically, maximum depression in rate of protein synthesis in the dystrophic retina occurs before maximum elevation of the shunt. The significance of this observation remains to be assessed. It could possibly represent some form of 'feed-back' mechanism within the tissue. In this respect, it has recently been suggested[11] that a metabolic coupling exists between the shunt mechanism and protein biosynthesis since there is a striking parallel between the activities of these two metabolic pathways in a number of mammalian tissues. Experiments are in hand to determine whether the depression in protein synthesis or the elevation in activity of the shunt mechanism is directly concerned with the structural breakdown in the dystrophic retina.

ISOTOPIC EXCHANGE AT EQUILIBRIUM AS A CRITERION OF ENZYMATIC MECHANISMS

By DR. J. TZE-FEI WONG and PROF. CHARLES S. HANES, F.R.S.

Department of Chemistry, University of Oregon, Eugene, Oregon, and Department of Biochemistry, University of Toronto, Canada

KINETIC criteria proposed for the diagnosis of enzymatic mechanisms have been based mainly on initial reaction velocities, but some use has been made of correlations between equilibrium constants and initial rate behaviour, that is, the Haldane relations. The possibility of developing criteria of these categories to differentiate between the variety of branching and linear mechanisms which may operate in the important class of group-transferring enzymes was examined in a recent generalized investigation by us[1]. Now an additional kind of kinetic criterion for the differentiation of mechanisms has been recognized by Boyer[2] and Boyer and Silverstein[3,4], who have pointed to the potential diagnostic value of studying the rates of isotopic exchanges in enzymatic systems at equilibrium. It is proposed here to consider this new criterion in the light of the generalized theory already referred to which, built on the determinant method of King and Altman[5] for solving the steady-state equations, permits a direct visualization of the rate consequences of enzymatic mechanisms.

A group-transfer reaction may be represented:

$$GX + Y \rightleftharpoons X + GY \qquad (1)$$

In the system at equilibrium there will be no net change in the concentrations of these reactants, but, if a minute quantity of GX or X labelled isotopically in the X-moiety be added, the exchange of the labelled X-moiety between GX and X may be measured. For a number of specific mechanisms Boyer[2], Morales, Horovitz and Botts[6], and Boyer and Silverstein[3] derived rate expressions for such exchanges and these can be used to evaluate rate parameters. This led to the proposal of the exchangeability criterion to differentiate between reaction mechanisms. Consider, for example, the exchange of X-moiety between GX and X; if the concentrations of the other pair of reactants, GY and Y, are made very large, the exchange of X-moiety may or may not become completely blocked, depending on the mechanism. Thus the blocking or lack of blocking of exchanges may serve as a criterion of mechanisms.

In what follows, a simple and direct method is described for ascertaining for any given mechanism whether or not an exchange between one pair of reactants will be subject to blocking when the concentrations of the other pair of reactants are raised to saturating levels, the system remaining at equilibrium. This method, in common with the generalized featurewise method of kinetic analysis developed earlier, depends on defining the precise features, possibly common to many mechanisms, which will be responsible directly for the particular rate effect in question; in this case, the blocking or lack of blocking of a specified exchange reaction. As will become clear, this featurewise approach avoids some special assumptions made in deriving rate equations for exchange reactions (cf. Morales, Horovitz and Botts[6]) and it is applicable easily to an unrestricted range of mechanisms, including complex examples for which the derivation of full-rate expressions has not been attempted and would present difficulty.

The principles of the method can be illustrated by considering the effects of high concentrations of GY and Y on the exchange of X-moiety between GX and X:

(1) Let $[GY, Y]$ represent the concentrations of GY and Y (present always in the proper proportions to maintain the equilibrium state). As $[GY, Y]$ becomes very large, some of the enzymatic species in the reaction mechanism will tend to vanish, while other species will persist in finite amounts.

(2) In the general case of a mechanism involving n enzyme-containing intermediates, $ER_1, ER_2, \ldots ER_n$ (including free enzyme as one of these species), the probability of the conversion of one species to another is called a kappa, which consists of the kinetic constant of the conversion step multiplied by the concentration of any non-enzymatic reactant taking part in the conversion, if there be one. Solution of the steady-state equations for the mechanism permits the fractional concentration of any one of the ER's to be expressed in terms of the kappas. Consider, for example, the mth species, ER_m. Its fractional concentration is represented as the ratio of two groups of terms, as follows:

$$\frac{[ER_m]}{[\text{total enzyme}]} = \frac{\Delta_m}{\Delta_1 + \Delta_2 + \ldots + \Delta_n} \qquad (2)$$

The denominator in equation (2) is common to the expressions for the fractional concentrations of all n species and equals simply the sum of the n respective numerators. Using a determinant method, King and Altman[5] derived a rule, rigorously established, which specifies clearly and comprehensively the composition of the terms present in Δ_m. Each term in Δ_m is a product of $(n - 1)$ different kappas. Schematically, these $(n - 1)$ kappas correspond to $(n - 1)$ reaction steps which lead either individually or in confluent and continuous sequences to ER_m; no kappa originating from ER_m is present in these terms which must therefore contain one kappa originating from each of the other $(n - 1)$ ER's present in the mechanism. The full expression for Δ_m is given by the sum of all possible kappa-products which conform to this description.

(3) Although, for any given mechanism, the full expression for Δ_m (and hence also the denominator terms $\Delta_1 + \Delta_2 + \ldots \Delta_n$, in full) can be written out by inspection, supplemented by sketching out schematic representations of all the possible pathways leading to ER_m*, it is rarely necessary or even helpful to develop such expressions in full detail. In the present connexion, as will become evident, the only relevant property of the terms comprising Δ_m (and the terms comprising $\Delta_1 + \Delta_2 + \ldots + \Delta_n$) is the highest degree of any of the terms with respect to GY and Y. The concept of the degree of a mechanism with respect to the concentration of a reactant was proposed[1] as a fundamental basis for the classification of enzymatic mechanisms, and its usefulness is illustrated again in the present connexion. Here we are concerned with the degree of terms in Δ_m with respect to two reactants, GY and Y, and this refers merely to the maximum number of times the concentration factors $[GY]$ and $[Y]$ appear in any terms in Δ_m, that is, the maximum number of times $[GY]$ and $[Y]$ can appear in any kappa-product present in Δ_m. If there are z different ER's in the mechanism which react with GY or Y or both GY and Y, the degree of Δ_m with respect to $[GY, Y]$ cannot exceed z. The procedure then is to ascertain by inspection and sketching of schematic terms whether there is a kappa-product leading to ER_m in which $[GY]$ and $[Y]$ can appear z different times, or failing this, whether there is a kappa-product leading to ER_m and in which $[GY]$ and $[Y]$ can appear $(z - 1)$ times, etc. Thus, starting from z, the degree of Δ_m with respect to $[GY, Y]$ can soon be reached. The degree of each of $\Delta_1, \Delta_2, \ldots \Delta_n$ with respect to $[GY, Y]$ is similarly reached. With practice, this is easily carried out and it usually requires no more than a few minutes to examine a mechanism and to sketch out schematically the kappa-products which are relevant.

(4) Once the degrees of the various Δ's with respect to $[GY, Y]$ have been established, it will become evident which ER's in a given mechanism will vanish and which will persist, when $[GY, Y]$ is made saturating. If the degree of the numerator is equal to that of the denominator in the expression for a particular intermediate ER_m, then ER_m will persist in finite amount when $[GY, Y]$ becomes very large. If, on the other hand, the degree of the numerator is lower than that of the denominator, ER_m will vanish when $[GY, Y]$ becomes very large. (It may be noted from equation 2 that the degree of the numerator cannot exceed that of the denominator, since the denominator, common to all the expressions, contains all the individual terms which are present in the respective numerator Δ's.)

(5) All reaction steps originating from a persisting enzymatic species in the mechanism will proceed at significant rates. Furthermore, since we are considering the system at equilibrium, the principle of microscopic reversibility dictates that all reaction steps leading to a persisting species must also proceed at significant rates. In terms of interconversions between different species, this means that the direct interconversion of two given species will continue at a significant rate if one or both species persists when $[GY, Y]$ becomes saturating. On the other hand, interconversions between pairs of species which both vanish will be insignificant.

(6) It is evident that the exchange of X-moiety between GX and X will not be blocked if an uninterrupted chain of significant interconversions constituting a pathway for the exchange persists when $[GY, Y]$ is increased to a saturating level, whereas the exchange will be blocked if the chain of interconversions is interrupted. Such interruptions will result if any two adjacent ER's present in such a chain of interconversions are caused to vanish as $[GY, Y]$ is made very large.

---

* In practice, for more complex mechanisms, it is more convenient to make use of a simple mathematical procedure to ensure comprehensive inclusion of all admissible terms; this is described by Wong and Hanes (ref. 1).

The considerations outlined in the foregoing paragraphs provide a general method for determining: (*a*) which ER's in a given mechanism will persist and which will vanish; (*b*) which interconversions will continue at a significant rate and which will fall to zero; and accordingly, (*c*) which potential pathways for the interconversion of GX and X will remain and which will be blocked when $[GY, Y]$ is made very large. The application of these principles may be illustrated by considering the series of mechanisms A–E. Here the enzymatic species which persist in the presence of very large $[GY, Y]$ are underlined, and significant interconversions are represented by solid arrows, whereas insignificant ones are shown by broken arrows. For each ER in these mechanisms there is shown in brackets the degrees with respect to $[GY, Y]$ of the numerator and denominator terms of the expression for its fractional concentration (cf. equation 2) derived by inspection as described above.

(In mechanism E, GY acts not only as a substrate, but also as a modifier by adding to a site represented as being on the left side of E to form GYE, which is able to function by combining with GX to form $GYEGX$.)

It will be seen by inspection of these diagrams that the exchange of the X-moiety between GX and X will be blocked in mechanism A, on saturation with $[GY, T]$, since no continuous chain of significant interconversions for bringing about the exchange remains, but in each of the other cases an uninterrupted chain for the exchange reaction will remain, as follows:

Mechanism

B $$\underline{EY} \overset{GX}{\rightleftharpoons} \underline{EGXY} \rightleftharpoons \underline{EGYX} \underset{X}{\rightleftharpoons} \underline{EGY}$$

C $$\underline{EY} \overset{GX}{\rightleftharpoons} \underline{EGXY} \rightleftharpoons \underline{EGYX} \underset{X}{\rightleftharpoons} \underline{EGY}$$

D $$\underline{E} \overset{GX}{\rightleftharpoons} \underline{EGX} \underset{GY}{\overset{Y}{\rightleftharpoons}} \underline{EX} \underset{X}{\rightleftharpoons} \underline{E}$$

E $$\underline{GYE} \overset{GX}{\rightleftharpoons} \underline{GYEGX} \underset{GY}{\rightleftharpoons} EGX \overset{Y}{\rightleftharpoons} \underline{EGXY} \rightleftharpoons \underline{EGYX} \underset{X}{\rightleftharpoons} \underline{EGY}$$

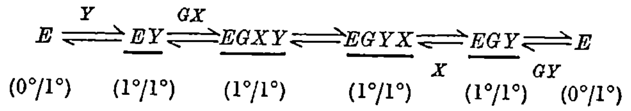
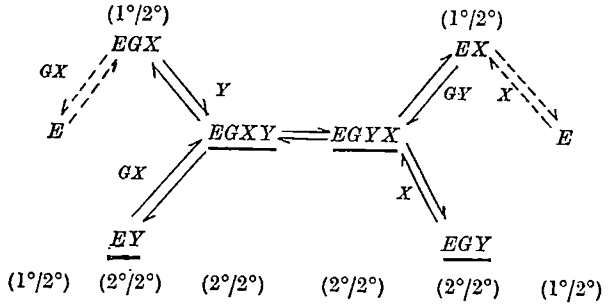
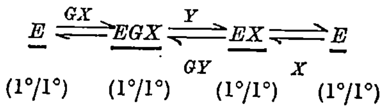
B



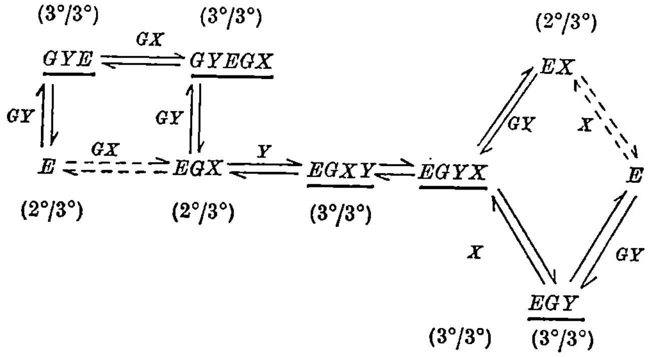
C



D



E



It was suggested by Boyer[2], and Boyer and Silverstein[3,4] that the blocking of an exchange between one pair of reactants by high concentrations of the other pair might prove to be characteristic of a linear reaction pathway (compulsory order) and that lack of blocking might be characteristic of branching (alternative) pathways. The above examples show that this is not strictly the case. Mechanism C (with dead-end branches) has a compulsory order of reaction, but the various exchanges will not be blocked by saturation with any pair of reactants. In mechanism D, the exchange reaction between GX and X cannot be blocked by high concentrations of GY and Y, but can be blocked by high concentrations of GX and GY, or of X and Y, that is, one of GX and X has to be saturating in order to block its own exchange reaction.

Mechanism E is of particular interest in showing that the action of GY as a modifier has changed a mechanism for which blocking of the exchange of X-moiety by high $[GY, Y]$ is predicted, into one which will not be blocked. It illustrates the further interesting feature referred to earlier that virtual deletion of a single intermediate by high $[GY, Y]$ does not interrupt the continuity of significant interconversions through this intermediate.

We have been interested especially in mechanism E as representing one of the very few mechanisms which appears capable of providing an explanation for a wide range of features of initial rate behaviour exhibited by the alcohol dehydrogenase of horse liver, to be reported shortly elsewhere. It seemed at first that the observations of Boyer and Silverstein[4], showing that isotopic exchange between NAD+ and NADH is not blocked by high concentrations of alcohol–acetaldehyde (in equilibrium proportions) in this same system, might constitute evidence against this mechanism but, as will be evident from the foregoing analysis, this is not the case. It is pertinent to note that mechanism D, which corresponds to the mechanism proposed originally by Theorell and Chance[7] for the liver alcohol dehydrogenase reaction, is now shown also not to be subject to blocking by high [alcohol–acetaldehyde]. However, on grounds to be presented elsewhere, this mechanism appears inadequate to explain a number of diagnostic features of rate behaviour which have been observed.

We thank Prof. P. D. Boyer and Dr. E. Silverstein for permitting us to read in advance of publication their observations on equilibrium reaction rates occurring in different enzymatic systems, and also for helpful discussions on the interpretation of isotopic exchanges at equilibrium.

EXPRESSION OF POLYOMA-INDUCED CELLULAR ANTIGEN(S) IN HYBRID CELLS

By Dr. V. DEFENDI*, Dr. B. EPHRUSSI and Dr. H. KOPROWSKI

Wistar Institute of Anatomy and Biology, Philadelphia, 4, Pennsylvania, and
Department of Biology, Western Reserve University, Cleveland, Ohio

THE occurrence of somatic hybridization in mixed *in vitro* cultures of two mouse cell lines was first observed by Barski *et al.* in 1960 (ref. 1), and soon thereafter confirmed by Sorieul and Ephrussi[2]. In 1962, Ephrussi and Sorieul[3] obtained a second somatic hybrid, designated *M*-109. This new hybrid was obtained in mixed cultures of the two following cell lines: (*a*) clone N.C.T.C. 2555, the 'low cancer' inducing line isolated by Sanford *et al.*[4] from a culture of subcutaneous connective tissue of a *C3H* mouse; (*b*) clone *Py*-198-1 isolated by Dulbecco and Vogt[5] from a culture of mouse (non-inbred Swiss) embryonic tissue 'converted' *in vitro* by polyoma virus. *Py*-198-1 is a clone of non-virus releasing cells characterized by multi-layer growth.

The conclusion that *M*-109 represents a line of hybrid cells was based on karyological evidence, namely, on the observation that these cells present a modal chromosome number approximating the sum of the modal chromosome numbers of the two parental lines[3,6] and contain marker chromosomes contributed by both parents. N.C.T.C. 2555 carried 11–16 bi-armed chromosomes and clone *Py*-198-1 several 'rabbit ear' chromosomes absent in the cells of the former line. Recently, this inference from the karyological investigation found support in the finding that *M*-109 cells carry four iso-antigens, three of which are carried by one of the parental lines, and one by the other[7].

The object of the present investigation was to establish whether cells of the parental line *Py*-198-1, 'converted' by polyoma virus, and those of line *M*-109 contain the cellular antigen(s) induced by the virus[8]. The presence of this antigen would provide additional proof of the hybrid nature of line *M*-109. Furthermore, such information is important for the elucidation of the mechanism whereby cells are 'converted' and become malignant as a result of virus infection. It will be recalled in this connexion that a similar investigation on a hybrid between a cell line derived from a polyoma-induced tumour and the well-known *L* line, obtained by Gershon and Sachs, indicated that "the polyoma-induced cell antigen may exist in the hybrid cells"[9]. This conclusion was based on a slight inhibitory effect on the size of tumours induced by the hybrid cells in the polyoma-immunized mice.

Since there was no available information concerning the ability of the *Py*-198-1 or of the hybrid cells to produce tumours, it was necessary to determine their ability to do so in order to conduct the standard experiment for the demonstration of the polyoma-induced transplantation antigen(s)[8]. Suspensions of viable *Py*-198-1 and *M*-109 cells were inoculated into 3–4-month-old *C3H/He* and *A/J* mice (obtained from Bar Harbor, Maine) either intracerebrally at a dosage as high as 10^6 cells per mouse or subcutaneously at a dose as high as 5×10^6 per mouse. In addition, an equal number of animals that had received 450 r. on the day of inoculation were treated in a similar manner. The mice used in these experiments differed at several histocompatibility loci from the cells[7]; however, no strains co-isogenic to these cell lines were available. No tumours were seen during a period of six months in the 40 *C3H/He* mice or 31 *A/J* mice (either irradiated or non-irradiated) which had been inoculated with various doses of *M*-109 cells or in the 49 *A/J* mice inoculated with *Py*-198-1 cells; indeed, not even temporary growth occurred. It is not possible to decide, at this stage, whether the failure to produce tumours with the *Py*-198-1 and *M*-109 cells should be attributed to an intrinsic inability to form tumours or to an antigenic constitution which differed from the host's.

It was therefore necessary to utilize a different method to test for the possible polyoma-induced transplantation antigen(s), that is, immunization of mice with tissue culture preparations and challenge with isologous polyoma-induced tumours.

Cells from the *Py*-198-1 and *M*-109 were collected by scraping from the glass surface, washed several times in phosphate buffered saline solution, and inoculated into panels of *C3H/Bi* and *C57/BL* mice at a dose of $7 \cdot 5 \times 10^6$ cells per mouse. Two subcutaneous injections and one intraperitoneal injection were given one week apart. One week after the final immunization, the mice were subcutaneously inoculated with the isologous polyoma-tumour cell suspension free of virus. The origin and characteristics of these tumours, as well as the demonstration of polyoma-induced transplantation antigens in these tumours, have been reported elsewhere[10]. The animals were examined bi-weekly for three months and tumour growth recorded. At the end of the experiments, mice of the various groups were tested for the presence of polyoma virus hæmagglutination inhibiting activity in

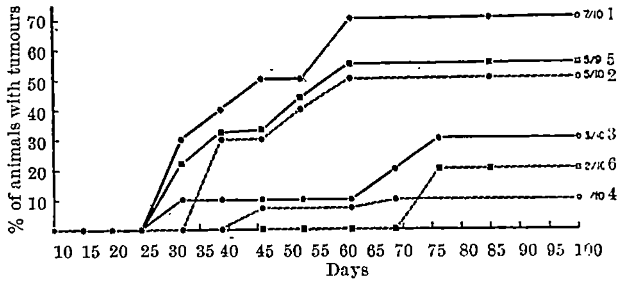

Fig. 1. Panels of *C57/BL* mice were immunized with *Py*-198-1 or *M*-109 cells twice subcutaneously and once intraperitoneally one week apart ($7 \cdot 5 \times 10^6$ cells per time/mouse) and were then challenged with $1 \cdot 5 \times 10^5$ or $0 \cdot 5 \times 10^5$ cells from an isologous polyoma-induced virus-free tumour. Curves 1 and 2, control; 3 and 4, immunized with *M*-109 cells; 5 and 6, immunized with *Py*-198-1 cells; 1, 3 and 5, $1 \cdot 5 \times 10^5$ cells; 2, 4 and 6, $0 \cdot 5 \times 10^5$ cells

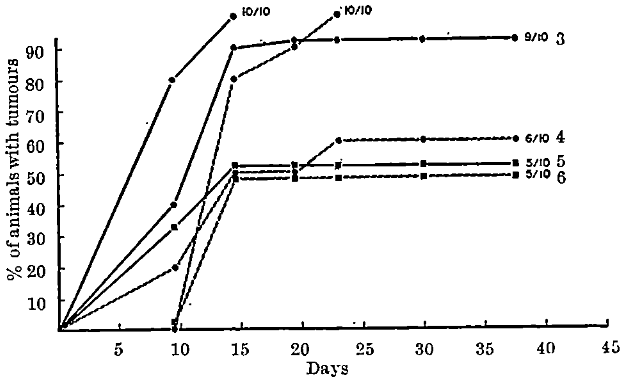

Fig. 2. Panels of *C3H/Bi* mice were immunized with *Py*-198-1 or *M*-109 cells twice subcutaneously and once intraperitoneally one week apart ($7 \cdot 5 \times 10^6$ cells per time/mouse) and were then challenged with 3×10^5 or 10^5 cells from an isologous polyoma-induced virus-free tumour. Curves 1 and 2, control; 3 and 4, immunized with *M*-109 cells; 5 and 6, immunized with *Py*-198-1 cells. 1, 3 and 5, 3×10^5 cells; 2, 4 and 6, 10^5 cells

Table 2. RESULTS OF COMPLEMENT-FIXATION TEST WITH PARENTAL AND HYBRID CELLS AGAINST SERUM FROM MICE BEARING POLYOMA TUMOUR*

	Antigen dilution						Anticomplementary activity of the antigen		
	0	2	4	8	16	32	0	2	4
N.C.T.C. 2555	0	0					0	0	0
L	0	0					0	0	0
Py-198-1	4	4	4	4	3	0	Tr.	0	0
M-109	4	4	4	0			Tr.	0	0
M-109 clone 3	4	4	4	0			Tr.	0	0

* These results were obtained with a 10 per cent cell homogenate in buffered saline solution tested in the presence of 8 C.F.U. of serum.

the sera. All the sera were negative; this confirms that polyoma virus was not present in the immunizing cells or in the challenging tumours. The results are given in Table 1.

In comparison with the non-treated mice, the *C3H/Bi* and *C57/BL* mice that had been pre-immunized with the *M*-109 and *Py*-198-1 cells showed resistance to transplants of the respective isologous tumour cells at least at the two doses of challenge cells used. Furthermore, the appearance of tumours in the immunized animals was considerably delayed in comparison to the controls, as illustrated in Figs. 1 and 2. In general, immunization with *Py*-198-1 cells seemed to be more effective than with an equal number of *M*-109 cells. The resistance phenomenon was also more clearly shown in the *C3H/Bi* mice than in the *C57/BL* mice. The degree of resistance demonstrated in these tests is comparable to that reported by Sjögren[11] when different mouse strains were immunized with homologous polyoma-induced tumours and then challenged with isologous polyoma tumours. It may then be concluded that the polyoma-induced transplantation antigen(s) was present in the hybrid cells as well as in the parental polyoma-transformed cells, possibly, though, only to a minor extent in the former.

Further characterization of these cells was done by utilizing the fact that sera obtained from hamsters and mice bearing large polyoma-induced virus-free tumours fix complement when tested with saline extracts of these tumours. The specificity of this reaction is assured by the fact that these sera do not react with the original inducing virus, nor with extracts from tumours induced with different viruses in the same species, although they will cross-react with the tumours induced by the same virus in different species. Furthermore, the activity of these sera is not removed after absorption with sheep red cells[12].

In these tests, sera from hamsters carrying a transplantable polyoma tumour and sera from *C57/BL* mice with transplantable polyoma tumours were used. Tissue-culture cells to be tested for the presence of antigen were suspended in 10 per cent volume in phosphate buffered solution, dispersed and broken by repeated vigorous pipetting, and the suspension tested against the sera of the animal carrying the tumour. A typical test conducted with mouse sera is illustrated in Table 2. Even when undiluted, extracts of the N.C.T.C. 2555 cells and of a line of *L* cells carried in our laboratory did not fix complement, while extracts of *Py*-198-1 cells fixed complement at a dilution of 1 : 16 and the hybrid *M*-109 and a clone, *M*-3, derived from it were positive at a dilution of 1 : 4.

Thus, the complement-fixation test for polyoma-induced antigen also indicates that the hybrid line presents some of the characteristics of one of the parental lines. Although no definite conclusions have as yet been reached, the polyoma tumour complement fixing antigen and the transplantation antigen are probably different since one can be demonstrated in the absence of the other[13].

The presence of the polyoma-induced antigen(s) in the hybrid cells does not provide an answer to the still unresolved question of whether the viral genome, or a part thereof, is continuously present in the converted cells[14]. However, the persistence of this (or these) antigen(s), established by the foregoing experiments, will have to be taken into account in any interpretation of polyoma oncogenesis.

AN EFFECT OF INTERFERON ON UNINFECTED CHICK EMBRYO FIBROBLASTS

By DR. JOSEPH A. SONNABEND

National Institute for Medical Research, Mill Hill, London, N.W.7

INTERFERON inhibits the synthesis of virus specific RNA in chick embryo fibroblasts (CEF) infected with Semliki Forest virus[1]. The following is a report on the inhibition of RNA synthesis in uninfected CEF by a partially purified interferon. Crude preparations were used in previous investigations[2,3] on the action of interferon on the uninfected cell, and this probably accounts for the variable results reported.

The interferon used in these experiments was kindly supplied by Dr. J. Beale of Glaxo Laboratories. It had been purified from allantoic fluid obtained from influenza virus infected eggs and contained 1 mg protein and 2,000–4,000* units interferon per ml. It contained only very small amounts of ribonuclease (400 mμg/ml. in the undiluted material)

The conditions of culture of the CEF were as described by Taylor[1]. RNA was extracted from cultures of CEF which had been exposed to tritiated uridine or tritiated adenosine following a period of pretreatment with interferon. Where incorporation into total acid precipitable RNA was examined, the extraction was by a modified Schmidt–Thannhauser procedure[4]. RNA was estimated

---

* One unit of interferon is the amount which reduces the number of plaques by 50 per cent in a standard assay. The method used for purifying the interferon has recently been described (Fantes, K. H., O'Neill, C., and Mason, P. J., *Biochem. J.*, **91**, 20; 1964). However, the material used in these experiments had not passed through a DEAE-cellulose column.

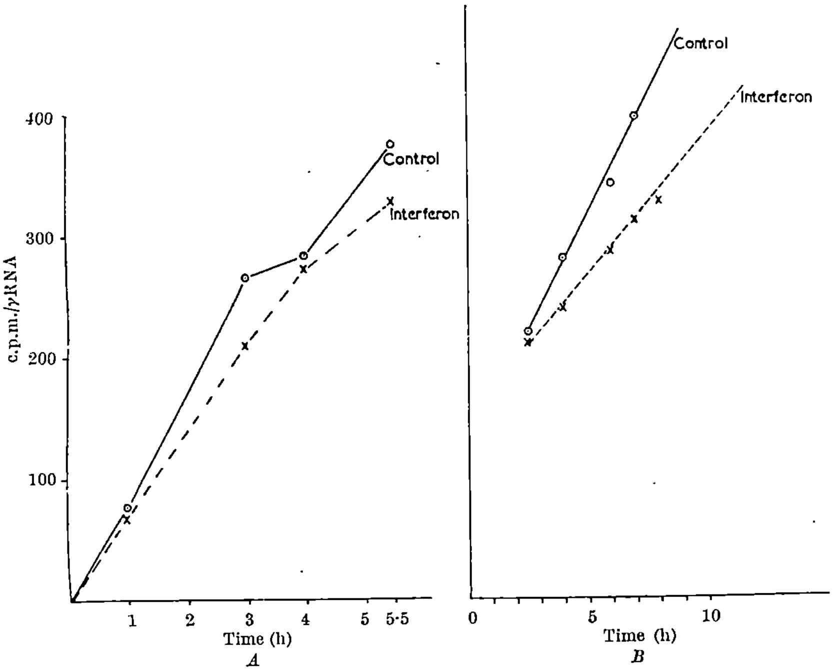

Fig. 1. Specific activity of RNA extracted from CEF treated with 10 units/ml. interferon for 24 h before addition of tritiated adenosine (*A*), and 50 units/ml. interferon for 5 h before addition of tritiated uridine (*B*)

on the alkali hydrolysate by the orcinol method[5]. In some experiments RNA was extracted with water-saturated phenol at room temperature. The interphase was re-extracted with phenol and sodium lauryl sulphate at 60° C when sucrose gradient analyses were undertaken; alternatively it was hydrolysed with alkali for determination of the specific activity of the RNA. Linear sucrose gradients (5–20 per cent sucrose) were run for 4½ h in the *SW*39 rotor of the Spinco model *L* ultracentrifuge and 12 drop fractions collected. Tritium was counted in a Tri-Carb scintillation counter.

Figs. 1*A* and *B* show an inhibition of incorporation of precursor into RNA following a period of pretreatment with interferon. In the experiment shown in Fig. 1*A*, 24-h-old CEF were treated with 10 units/ml. interferon for 18 h, 10 μc. tritiated adenosine was added to each plate and at the indicated times plates were removed and the specific activity of the total acid precipitable RNA determined. The effect of pretreatment for 5 h with 50 units/ml. interferon is shown in Fig. 1*B*. Following exposure to interferon, tritiated uridine (10 μc. per plate) was added to the cells, which were kept at 4° C overnight. After starting incubation at 37° C plates were removed at the indicated times. A further control showed that normal allantoic fluid had no effect on RNA synthesis.

There was little difference in the specific activities of the RNA extracted from interferon-treated and control cells following a 1-h labelling period. The largest differences in specific activity were observed after exposure of the cells to labelled precursor for 6 h. In a representative experiment, where cells were treated with 50 units/ml. interferon for 5 h, the specific activity of the RNA extracted from interferon-treated cells was 95 per cent of that in the controls after a 2·5-h labelling period, whereas after 8 h it had fallen to 70 per cent. An attempt was made to ascertain whether the synthesis of a specific molecular species of RNA was preferentially inhibited in the interferon-treated cells. Cells were treated with 100 units/ml. interferon for 18 h. Tritiated adenosine was added for 6 h and the RNA extracted with water-saturated phenol at room temperature. The interphase was re-extracted with phenol and sodium lauryl sulphate at 60° C and both RNA fractions analysed by sedimentation in a sucrose gradient. The sedimentation profile of both RNA fractions from the interferon-treated cells showed no marked difference from the controls. Fig. 2 shows the sedimentation pattern of the RNA extracted with phenol at room temperature from interferon-treated cells. It did not differ from the controls.

Levy, Snellbaker and Baron[3] suggested that a possible explanation for the delay they observed in the appearance of label in cold phenol-extractable RNA following interferon treatment was that there was an inhibition of transfer of RNA from nucleus to cytoplasm. The results of an experiment shown in Fig. 3 do not support such a mechanism. In this experiment CEF were treated with 50 units/ml. of interferon for 18 h before addition of tritiated adenosine. At the indicated times, samples were removed and extracted with water-saturated phenol at room temperature. Specific activities were estimated on the phenol-insoluble RNA at the interphase and on the RNA released into the aqueous phase. It can be seen that there is a reduction of incorporation of precursor into both the rapidly labelled and phenol-extractable fractions. Treatment with interferon resulted in a reduction of total counts as well as of specific activity.

The results showed an inhibition of RNA accumulation in interferon-treated cells; an effect on a particular species of RNA was not demonstrated. However, since RNA synthesis was examined only after some hours of interferon treatment, it is possible that the general inhibition observed was a consequence of an earlier specific

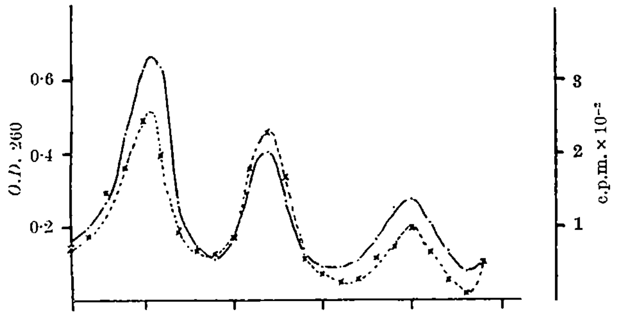

Fig. 2. Sucrose-gradient analysis of RNA extracted with phenol from CEF treated with 100 units/ml. interferon for 18 h. Tritiated adenosine was added for 6 h before extraction of the RNA. —·—, Optical density; ×, c.p.m.

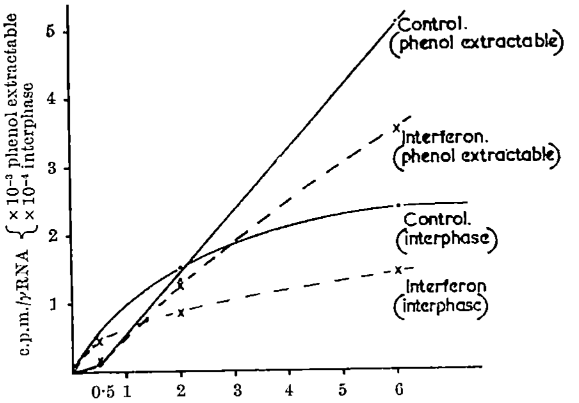

Fig. 3. Specific activities of phenol-insoluble and phenol-extractable RNA from CEF treated with 50 units/ml. interferon for 18 h

effect on a particular species of RNA. It is also possible that the effects observed in these experiments were due to impurities in the preparations; however, normal allantoic fluid did not inhibit RNA synthesis.

Taylor has shown that the antiviral action of interferon depends on continued host cell RNA synthesis and suggested that there may be a similar dependence on host cell protein synthesis[1]. That protein synthesis is required for interferon action has been demonstrated[6], and it was suggested that the antiviral action of interferon results from the induced synthesis by the host cell of a protein which inhibits viral RNA synthesis. The results presented here suggest that the activity of this protein may not specifically inhibit the synthesis of viral RNA; the accumulation of host cell RNA is also inhibited. A possible mechanism is that interferon induces the synthesis of an unstable enzyme which degrades newly synthesized RNA, host cell as well as viral. The induced synthesis by interferon of an unstable activity limiting the accumulation of RNA would account for the inhibition of both RNA and DNA viruses, as well as providing a basis for a self-limiting process allowing for a recovery of cell RNA synthesis. An explanation for the species specificity[7] of interferon action might be that it is only interferon of appropriate specificity that can induce the synthesis of the antiviral protein. Interferon production as well as interferon action is sensitive to actinomycin *D* (ref. 8). One implication of this observation is that those viruses which inhibit host cell RNA and protein synthesis will be poor interferon producers.

It should be possible to demonstrate whether the observed inhibition of RNA accumulation in interferon-treated cells results from an increased breakdown of newly synthesized RNA or from an inhibition of its synthesis.

A further point is that interferon action as well as interferon production provide possible examples of induced protein synthesis in mammalian cells and suggest a system for the investigation of these processes.

I thank Drs. Joyce Taylor, Robert M. Friedman and E. M. Martin for their advice, and Mr. David Haswell for his assistance.

EFFECTS OF HYPOXIA ON THE RABBIT DURING EXPOSURE TO COLD

By Dr. BRYAN BROOM*

Department of Physiology, Middlesex Hospital Medical School, London, W.1

HYPOXIA is known to decrease the augmentation of oxygen consumption seen in warm-blooded animals on exposure to cold[1-3]. It has been suggested that hypoxia is an essential ingredient in the duet of hypercapnia and hypoxia that is found in the autonarcosis technique of profound and reversible hypothermia with prolonged cardiac arrest[4,5]. The role of hypoxia in the cooling process is of clinical importance, as the depression of oxygen uptake by anæsthesia is the basis of all cooling procedures, whether internal or external in type.

Despite the invariable increase in oxygen consumption seen in warm-blooded animals on exposure to cold[6], there is as great an increase seen on exposure to heat[7,8]. Although the initial uptake of oxygen on cold exposure is near maximal[2], there is no inhibition of cooling[9], and in exposure to acute cold there is a linear decrement of oxygen consumption which parallels decrease in body temperature[10], a relationship which is not altered in the hypothermia seen in the cold-adapted animal subjected to severe chilling[2]. In the adaptation to cold seen in prolonged exposure, there is a decline of oxygen consumption towards basal levels[11]. The phylogenetic recapitulation of thermo-regulation seen in the developing house wren[12] and suckling mouse[13] shows that the stabilization of adult temperature correlates more precisely with adult size and insulation than with uptake of oxygen.

If the chemical regulation of heat production is an inefficient process[14], and it is in the physical regulation of heat loss that one must assess the characteristics of the well-adjusted homeotherm[15], then an attempt quantitatively to differentiate these aspects is needed. Hypoxia provides a basis for the assessment of the relative importance of the two processes.

The following experiments were performed to determine the effects of hypoxia, with and without concomitant hypercapnia and/or anæsthesia, on the body temperature and survival time of the rabbit in a known and limited supply of oxygen, both at neutral (14°–18° C) and reduced (–18° to –24° C) ambient temperatures. With a finite oxygen store, the survival time of the rabbit will depend on the rate of oxygen utilization, as influenced by the ambient temperature, the inspiratory carbon dioxide concentration and the presence or absence of anæsthesia. This situation offers a simple and reliable method of assessing the effects of body temperature changes on oxygen consumption that is free of the errors otherwise avoidable only by elaborate instrumentation[3].

Ninety-six rabbits of various strains were used, 48 for each of the two ambient temperatures. The rabbits were clipped of their fur under pentobarbitone anæsthesia more than 48 h before the experiment, prior to which they were allowed free access to food, 'Diet *S.G.*1', and water. The rabbit was placed in a cylindrical 7-l. tin, 25 cm × 15 cm, having at one end a detachable lid, and at the other a 'Perspex' attachment, 12·5 cm × 12·5 cm × 12·5 cm. 100 g fresh silica-gel was placed in the 'Perspex' attachment before the experiment, and also, in those experiments in which carbon dioxide enrichment was not practised, 100 g fresh soda lime. After an initial period of 10 min in the tin, air, or 30–32 per cent oxygen (both with or without 10 per cent carbon dioxide), was passed through the tin at about 3 l./min for 2 min, after which the rubber tubes passing to and from the tin were rapidly occluded with spring- and gate-clips, the lid having previously been sealed with adhesive plastic tape. The choice of pentobarbitone and/or oxygen or carbon dioxide enrichment was made by prior random selection. The initial and final ambient and colonic temperatures were noted, as was the time to respiratory arrest. The absence of leaks was checked by subsequent immersion of the tin in water.

From the results shown in Tables 1 and 2, it can be seen that hypoxia markedly reduces the body temperature in the cold, but only moderately at neutral ambient temperature. However, the cooling rates in hypoxia are half those found with normoxia; the carbon dioxide-induced acceleration of hypothermia is abolished and the pentobarbitone-induced acceleration of hypothermia is nearly halved[16]. In contrast to normoxia, prolongation of

---

* Beit Memorial Research Fellow.

An Introduction to Comparative Biochemistry

ERNEST BALDWIN

A comparative survey of some of the basic biochemical mechanisms found in animals. Professor Baldwin shows how biochemical differences between organisms reflect the differences in their environment and evolutionary history. This book is primarily intended for the student beginning biochemistry and the interested layman. The new edition has been thoroughly revised. *Fourth edition,* 16*s. net*

The Physiology of Diurnal Rhythms

JANET E. HARKER

A stimulating review of what is known of diurnal rhythms, especially those found in animals. Dr Harker demonstrates the universality of these rhythms, discusses the environmental factors which influence them and considers various possible 'biological clock' mechanisms. The book suggests many useful lines for further research. *Cambridge Monographs in Experimental Biology, 13.* 20*s. net*

NEW HEYWOOD BOOKS

PROGRESS IN CONTROL ENGINEERING Vol. 2

Edited by R. H. Macmillan
T. J. Higgins and P. Naslin

Six international critical reviews from Great Britain, France, Holland and the U.S.S.R. Subjects covered are : Topological Approach to System Analysis ; Process Parameter Estimation ; Principles of Computers and Their Application in Research ; Stability Analysis for Linear and Non-Linear Systems Using Liapunov's Second Method ; Finite Automata ; Disturbance Control.

292 pages. Royal 8vo. **70s.**

PROGRESS IN INDUSTRIAL MICROBIOLOGY Vol. 5

Edited by D. J. D. Hockenhull

Critical reviews from Great Britain, the U.S.A. and Japan. The latest volume in this series contains articles on various aspects of sterilization and the production of drugs and antibiotics. All microbiologists, bacteriologists, biochemists and pharmaceutical chemists will welcome this latest addition to a series which aims at keeping workers in applied microbiology up to date with current significant developments in special subjects in their field.

326 pages. Royal 8vo. **84s.**

STRESS ANALYSIS AND VIBRATIONS OF ELASTIC BODIES

T. V. Duggan

This book is unique in its parallel treatment of stress analysis and vibrations. Particular attention is paid to practical methods of solution in order to show the reader how to apply the theory to actual design problems. Strain energy methods are used extensively and unworked examples are given at the end of each chapter. Intended primarily for design engineers the book also covers the syllabus for most degree, diploma and H.N.C. courses and is designed to fill the gap in the literature suited to the present-day standard of mechanical engineering education.

580 pages. DIN A5. Illustrated **105s.**

Obtainable from all booksellers or direct from the publishers

Introduction to Plasma Physics
MARTIN A. UMAN *77s 6d*

This textbook for engineering and physics students introduces the physical and mathematical concepts of all branches of plasma physics and its applications to such areas as radio propagation, astrophysics and magnetohydrodynamics.

Theory of Turbomachines
G. T. CSANADY £5 10*s*
McGraw-Hill Series in Mechanical Engineering

A unified treatment of the principles governing the operation of turbomachines which covers all essential modern developments. These include the work on cascade mechanics by Schlichting's Braunschweig group and Knapp's research on cavitation in California.

The Testing and Inspection of Engineering Materials 3/e
H. E. DAVIS, G. E. TROXELL & C. T. WISKOCIL *74s*
McGraw-Hill Series in Civil Engineering

The revision of this leading text for courses in engineering materials collates the most important information from periodical literature and draws on recent research to illustrate many aspects of material behaviour. Material added includes new testing machines and devices, greater emphasis on ultrasonic tests, and the use of penetrants in non-destructive testing, treatment of experimental stress analysis by use of photoelasticity, and new tests of metals at low temperatures and short time tests at high temperatures. The first part of the book develops general concepts of testing, and the second illustrates methods of conducting common tests.

Experimental Biology MEASUREMENT AND ANALYSIS

R. H. KAY, M.A., D.Phil., A.Inst.P., Senior Research Officer, Department of Physiology, Oxford University.

Provides an excellent aid for understanding all the physical measurements of modern biology—plus an up-to-date and comprehensive set of references for further reading. The book covers the essential principles of the most important experimental techniques in biology. **84s.**

New Methods of Analytical Chemistry

(Second Edition)

R. BELCHER, D.Sc., F.R.I.C., Professor of Analytical Chemistry, University of Birmingham

C. L. WILSON, Ph.D., D.Sc., F.R.I.C., F.I.C.I., Professor of Analytical Chemistry, The Queen's University of Belfast.

In association with T. S. West, Ph.D., D.Sc., F.R.I.C., Reader in Analytical Chemistry, Imperial College, University of London.

Since the first edition of this book appeared some branches of "classical" analytical chemistry have grown considerably and several new sections are now included : primary standards now occupy a separate chapter ; the sections on precipitation from homogeneous solution and on solvent extraction are very much expanded ; there is also a new chapter on spectrophotometric reagents and a new section on reagents analogous to EDTA. **60s.**

Fertilizer Nitrogen ITS CHEMISTRY AND TECHNOLOGY

Edited by **VINCENT SAUCHELLI,** Consultant.

Extraordinary growth of the synthetic nitrogen industry has created a demand for reliable information on its current status, especially as it relates to the fertilizer industry. Except for changes and improvements noted in technical journals (and in one book not yet translated into this language), this authoritative Monograph is the first to answer this need—bridging a thirty-year gap to provide a single source of reference on the progress of synthetic ammonia and its derivatives. The articles cover every facet of the nitrogen industry, revealing current views from industries and universities, on a practical as well as theoretical level. A Reinhold Book. **140s.**

THE HISTORY OF THE STUDY OF LANDFORMS

Volume I. GEOMORPHOLOGY BEFORE DAVIS

Richard J. Chorley
Antony J. Dunn
Robert P. Beckinsale

This volume is the first of a series which will review and analyse the development of the study of landforms, from both the geographical and geological point of view, with especial emphasis upon fluvial geomorphology. With more than 120 half-tone and line illustrations. **84s.**

BIOCHEMISTRY OF SEMEN

AND OF THE MALE REPRODUCTIVE TRACT

Thaddeus Mann

This book represents the first attempt to provide a comprehensive and up-to-date treatise, and in this new edition its scope has been considerably enlarged ; it now includes information on the biochemistry of the male reproductive tract.
With 18 half-tone illustrations and 15 figures. **5 gns.**

THE FARADAY SOCIETY

A GENERAL DISCUSSION ON

Dislocations in Solids

15th, 16th and 17th September, 1964

At the invitation of the Deutsche Bunsen Gesellschaft a General Discussion of the Faraday Society will be held at the University of Göttingen. The Discussion will be concerned predominantly with ionic and network crystals and the formation, detection and measurement of dislocations with emphasis on the structural, energetic and micromechanical properties. It was originally intended to exclude metals but as this would lead to certain omissions in the more general and fundamental aspects of the subject, papers which are largely confined to general aspects of dislocations emerging from a study of metals will also be included.

Programmes may be obtained from:

CAN THE WATSON STEREO RANGE HELP YOU? Any operation in laboratory, workshop or assembly line which calls for the use of precision optics will benefit from the application of a Watson Stereoscopic Microscope. Operator convenience, optical performance and mechanical reliability have been combined in a range of instruments offering outstanding quality and value. A wide choice of assemblies makes light work of the most difficult location and job requirements.

Choice of Equipment

Watson eyepieces and objectives allow a choice of magnification, field of view and working distance appropriate to any task in the laboratory or on the production assembly line. A similar freedom of choice in stands and mountings meets the needs of the most difficult locations. A comprehensive range of illuminating systems* and accessories adds even more to the versatility of Watson Stereoscopic Microscopes.

* **including the *new* Fluorescent Illuminator**

Optical Quality

Depth and size of field are particularly important in instruments of this type. Watson Stereo Objectives achieve maximum depth and size of field without sacrifice of image quality. Objectives and eyepieces are manufactured to rigorous standards and are computed to give long working distances and visual fidelity of the highest order.

Please write for full details of this outstanding range of stereoscopic microscopes which includes the advanced "Research" model designed to satisfy the most exacting conditions.

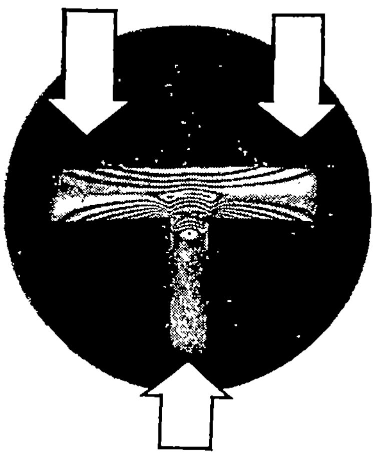
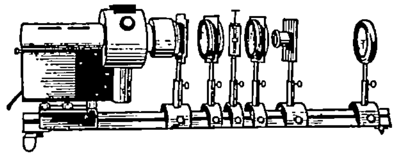
REVEALING THE EFFECTS OF

← STRESS →



IMPORTANT APPLICATIONS OF SPINDLER & HOYER OPTICAL BENCHES



Beam of light from carbon arc lamp is gathered in optical condensers, transmitted through polarizing screen, specimen, analysing screen and objective, which projects it on viewing screen. Spindler & Hoyer optical benches feature an automatic feeding device to move carbons uniformly through the lamp and eliminate adjustment. A wide range of sliding carriages and other accessories makes them extremely versatile.

(2) TEACHING

When specimens of plastic or special glass are fitted to a Spindler & Hoyer optical bench and subjected to stress, an image showing the effects is projected for observation. It may be filmed or photographed as a record. The instrument provides lecturers with a particularly graphic means of illustrating the principles of mechanics at work.

Industrial applications are numerous—Spindler & Hoyer optical benches are valued as time and money-saving equipment in many leading laboratories. For example, they are used to test glass and plastic mixes and product designs before manufacture, and to investigate the effects of stress on engineering projects at the technical design stage. For full details, please contact the sole U.K. distributors,

The Scorah OXY-COAL GAS BLOW PIPE

specially for working BOROSILICATE GLASSES (Pyrex, Phoenix, Hysil, etc.)

- Five jets and central pilot light — flame size selected INSTANTANEOUSLY.
- Rotating turret head for easy jet selection.
- Auxiliary supply of oxy-coal mixture for hand torch.

Minimum oxygen consumption
Maximum economy

A modern oxy-coal gas blow-pipe of sturdy construction evolved through years of practical experience in glass manipulation. A nearly silent flame from pin point to one capable of working 100 mm. tubing at a flick of the turret. To the inexperienced it gives confidence, to the experienced it is an assurance of efficiency and successfully completed work. A unique instrument for the research laboratory or workshop. Send for Leaflet BP/N2.

Obtainable only from Price **£25.0.0**

Tables 1 and 2. SURVIVAL TIMES AND COOLING RATES IN HYPOXIA
(Corrected for body-weight)

Table 1. MEAN SURVIVAL TIMES (MIN)

Gas mixture/ anæsthesia	14°–18° C	Significance (analysis of variance, %)	−18° to −24° C	Significance (analysis of variance, %)
Pentobarbitone	94·8	0·1	148·8	0·1
No pentobarbitone	66·7		89·4	
Oxygen	90·6	0·1	164·6	0·1
Air	70·8		100·8	
Oxygen/CO$_2$	No difference		114·2	5·0
Air/CO$_2$			96·7	

Table 2. COOLING RATES (° C/MIN)

Pentobarbitone	0·041	0·1	0·108	0·1
No pentobarbitone	0·018		0·078	

Note. No correlation of cooling rate with carbon dioxide or oxygen.

survival time is replaced by a diminution of survival time by carbon dioxide inhalation as compared with pentobarbitone anæsthesia. Thus, despite the increase of oxygen uptake by carbon dioxide that is seen in hypoxia, this is insufficient to maximize cooling rates, and under the hypoxic stimulus only the diminution of oxygen consumption by pentobarbitone operates to increase cooling, a function that is curtailed in these circumstances. These facts substantiate the view that carbon dioxide operates by enhancing optimal oxygen uptake, with which both survival time and cooling rate may be maximal, in normoxia[16].

The results also demonstrate the protection conferred by prior anæsthesia[17], and hypothermia[18], against hypoxia. While carbon dioxide protects against hypoxia during the initial phases of exposure[19,20], it cannot be expected to continue this protection if persistent hypoxia is ultimately unrelieved[18–20].

That the combination of an increased oxygen uptake and increased cooling rate can occur is shown by earlier work in which thyroxin administration[1,9], and thyrotoxicosis[21], were found to increase cooling rate and heat loss, respectively, despite an increase of oxygen consumption to levels found in cold exposure. Similarly, the hyperthermic response by primary metabolic stimulation that is found on ergotoxine administration in an ambient temperature above 28° C is converted into a hypothermic response at an ambient temperature of 7° C, by adrenaline reversal, from peripheral vasodilation with consequent diminution of body temperature and hence of uptake of oxygen[22]. These phenomena show that circulatory factors may outweigh metabolic ones in the context of temperature regulation in the cold[23,24], and is compatible with the recent demonstration of simultaneous adaptation both to heat and cold in man[25].

During most of hypoxia, the vasomotor tone is high[26]. The fact that oxygen administration alone may initially inhibit temperature depression in the cold[27] and briefly, during hypoxia[26], can only be explained by an increase in peripheral vasomotor tone[26] and a resultant decrease in heat loss, as the inhalation of oxygen by unanæsthetized animals diminishes oxygen consumption[28]. Carbon dioxide is perhaps the only agent, apart from a condition of acidosis[29], that will simultaneously increase both oxygen uptake and blood flow[30].

Previous work on the mechanism of the hypothermic action of carbon dioxide during cold exposure[31 33] suggested it to be due to a diminution of oxygen consumption. Chapin and Edgar[33] used 32·5 per cent carbon dioxide, which is an anæsthetic concentration[34] and would thus be expected to decrease oxygen uptake. Repin[31] gave clear evidence of increased heat loss being responsible, yet equated this as being due to decreased heat production. Stupfel[32] found that 10 per cent carbon dioxide induced hypoxia and mimicked the oxygen uptake and the temperature depression seen with the inspiration of 11 per cent oxygen. Yet he found that the hypoxia associated, in his hands, with 20 per cent carbon dioxide could be relieved without abolishing the lowering of body temperature, and also that concentrations greater than 20 per cent did not further augment cooling but led to respiratory depression which killed the animal. Hence his maximal cooling rates were obtained with a concentration of carbon dioxide that was not associated with hypoxia. The results presented and discussed in this article resolve these discrepancies.

I thank Dr. Ian Sutherland for all statistical calculations, and Prof. E. Neil for his advice.

EFFECT OF TOBACCO MOSAIC VIRUS PROTEIN ON TOBACCO MOSAIC VIRUS INFECTIVITY

By DR. V. HOLOUBEK*

Department of Virology, University of California, Berkeley

THE infectivity of isolated TMV–RNA is only about 0·1 per cent of that of the same amount of RNA contained in TMV protein. After the addition to the TMV–RNA of the TMV protein under certain conditions the TMV reconstitutes, and full infectivity of virus particles can be restored[1]. If the TMV protein is added to an inoculum of TMV, depending on its concentration it causes either enhancement or decrease of virus infectivity.

* The numbers represent means of results from different assays, each assay based on 12 half-leaves compared with 12 half-leaves of the control.

The results, in numbers of lesions per half-leaf obtained with various mixtures, are expressed in terms of per cent of the lesion number obtained in the control half-leaves.

The present experiments were designed to evaluate some possibilities for the mechanism of this effect of TMV protein on TMV infectivity.

In all experiments, the TMV was prepared by the standard method of differential centrifugation from leaves of *Nicotiana tabacum* var. 'Turkish' infected with the common strain of TMV. The TMV labelled with carbon-14 was supplied by courtesy of Dr. P. R. Whitfeld. The viral RNA and protein were prepared as described[2,3]. The concentrations of the virus, the virus protein and the RNA were determined spectrophotometrically[4]. Ultra-violet inactivation was performed with a Westinghouse germicidal 'Sterilamp' placed 50 cm from the sample to be irradiated. The lamp had an ultra-violet output of 5·2 W and 95 per cent of its radiation was at 2537 Å. The RNA was irradiated at a concentration of 1·2 mg/ml. in distilled water in a 1–2 mm magnetically stirred layer. Reconstitution was carried out according to the method of Fraenkel-Conrat and Singer[1]. For some experiments the TMV protein was re-aggregated into rods in 0·1 M phosphate buffer at *p*H 5·2. Ovalbumin was a preparation obtained from Armour Laboratories, Chicago, Illinois. The ultracentrifuge analyses were made in a Spinco model *E* ultracentrifuge, operating at room temperature. Sedimentation coefficients were corrected to a standard state corresponding to water at 20°. Electron microscopic pictures were obtained by J. Toby through the courtesy of Dr. R. C. Williams. For infectivity tests the mixtures of TMV or TMV–RNA with different concentrations of proteins or inactivated TMV in water solutions were mixed with 0·1 volume of 1 M phosphate buffer at *p*H 7·0 at 0° and applied to 12 half-leaves of *N. tabacum* var. 'Xanthi *nc*'. Control TMV or TMV–RNA solutions in the same concentration was applied to the opposite half-leaves. Inoculation was carried out as described[4].

Suppression of TMV infectivity by TMV protein and other proteins. If an inoculum of TMV at a concentration of 0·01 μg/ml. was mixed with TMV protein in a concentration higher than 50 μg/ml., the increasing concentration of the TMV protein inhibited the infectivity of TMV, and at a concentration of 1,000 μg/ml. the protein suppressed the infectivity to a level lower than 1 per cent of the original infectivity (Table 1). The suppression by ovalbumin, protein having isoelectric point similar to that of TMV protein, was very similar.

Santilli *et al.*[5] suggested that the inhibition of TMV infectivity with TMV protein and other proteins was due to a reduction in number of particles resulting from aggregation. However, ultracentrifugation analysis of a mixture of TMV with TMV protein showed no aggregation of TMV particles, but two distinctive peaks, one of TMV protein and the other with a sedimentation coefficient of S_{20}–210 or 205 in two experiments, were observed. The decline of TMV infectivity to 1 per cent would require the aggregation of one hundred particles to an infectious unit, an aggregation which surely would manifest itself in the sedimentation coefficient. Also when samples of TMV which had been incubated with 10, 50, 250 and 1,000 μg TMV protein/ml. for 1 h at 4° were examined under the electron microscope, no indication of aggregation of TMV particles was found. Likewise, it was not possible to observe visible aggregation between ovalbumin and TMV.

From the results of ultracentrifugal analysis of the mixture of TMV protein with TMV it is possible to assume that, at higher concentrations of proteins in mixed inocula with TMV, they became adsorbed on the surface of TMV to such an extent that they prevented attachment of the virus at the susceptible sites in the plant cell. If instead of TMV *A*-protein solution the TMV protein aggregated in rods was used, the suppression of TMV infectivity was similar but lower than with TMV *A*-protein (Table 1). Probably the protein rods were not able to adsorb to the surface of TMV so easily as protein dissociated to basic sub-units (the TMV *A*-protein).

Suppression of TMV infectivity by inactivated TMV. TMV inactivated by ultra-violet radiation caused as much suppression of the TMV infectivity as TMV protein aggregated in rods. In contrast the suppression of TMV infectivity by TMV reconstituted from ultra-violet inactivated TMV–RNA and non-irradiated native TMV protein is notably bigger (Table 1). This may be explained by the assumption of different mechanisms of these two inhibitions. It is probable that the virus with inactivated RNA but with native protein coat can compete with TMV virus for the same potentially infectible sites of virus attachment in a similar way as the systemic strain U_2 of TMV suppresses the formation of lesion by the strain U_1 (ref. 6). The inactivation of the virus as a whole by ultra-violet radiation might lead to such changes in its protein coat that the irradiated virus cannot compete with the infective virus for the sites of virus attachment. The TMV infectivity suppressed by higher concentrations of this virus was probably suppressed by the same mechanism which caused the suppression of TMV infectivity by TMV protein. In this relation, the observation of Wu and Rappaport[6] is of interest, that the inhibitory effect of U_2 was decreased by its irradiation before mixing with the non-irradiated U_1.

Enhancement of TMV and TMV–RNA infectivity by TMV protein. In contrast to the inhibition of the TMV infectivity by high concentrations of TMV protein, the same protein in a concentration around 10 μg/ml. stimulated the TMV infectivity (Table 1). Similar results have been obtained by Santilli *et al.*[5]. It was not known whether or not partial reconstitution could be accomplished when the protein is mixed with TMV at low temperature and the mixture was inoculated 30 min after mixing, conditions which do not permit TMV complete reconstitution from TMV–RNA and protein. Samples ranging from 1 to 6 mg of TMV were mixed with 600 μg of TMV protein labelled with carbon-14 (activity of 8,140 counts per mg per min) and incubated for different time-intervals of 1–24 h in water solution at the temperature of 0°. After this incubation the TMV was washed by repeated ultracentrifugation (Spinco 40,000 r.p.m. for 1 h) and resuspended in water. The results of carbon-14 activity measurements showed that after 4 cycles the protein which

Table 2. EFFECT OF RUBBING TOBACCO LEAVES WITH PROTEINS AT DIFFERENT TIME-INTERVALS BEFORE AND AFTER TMV AND TMV–RNA INOCULATION

Tested protein	Time-interval between rubbing and inoculation	Protein concentration used for rubbing (μg/ml.)	No. of lesions as percentage of those of the control	No. of assays
	(*A*) Inoculation with TMV			
TMV protein	40 min before inoculation	15	101 ± 11·3[*]	3

[*] The numbers represent means of results from different assays, each assay based on 12 half-leaves compared with 12 half-leaves of the control.

The results are expressed in the number of lesions on half-leaves pre-treated at various time-intervals by rubbing with different protein concentrations, as percentage of number of lesions on half-leaves pretreated only by rubbing with water.

was at the beginning adsorbed to the viral particles was washed out to less than 0·1 per cent of the originally added amount. This low residual amount of carbon-14 activity was not dependent on the time of incubation. Such washed TMV had the same infectivity as the original TMV before addition of protein. For the rise as well as for the suppression of TMV infectivity the protein must be present in the inoculum at the time of infection. From these results it is possible to exclude reconstitution as an explanation of the enhanced effect of low concentrations of TMV protein on the TMV infectivity.

If the TMV–RNA at a concentration of 0·5 μg/ml. was mixed with TMV protein, the rise in the infectivity of this TMV–RNA was more than 100 per cent. In contrast to TMV, the TMV–RNA infectivity was stimulated also with concentrations of TMV protein which suppressed the infectivity of the virus (Table 1). The addition of ovalbumin was without effect on the TMV–RNA infectivity. The stimulation of the TMV–RNA infectivity was not due to reconstitution of TMV from the RNA and the protein added just prior to inoculation. Under such conditions (0° temperature and 0·1 M phosphate solution) no sedimentable particles were formed.

Changes in TMV and TMV–RNA infectivity after rubbing the tobacco leaves with TMV protein. If the TMV protein in water solution was rubbed on the tobacco leaves at different time-intervals up to 40 min before the inoculation with TMV or TMV–RNA, the number of lesions on these pre-treated half-leaves was, in the case of TMV–RNA, about 250 per cent, and in the case of TMV, about 150 per cent higher than on control half-leaves which were rubbed at the same time-intervals before inoculation only with water (Table 2). Rubbing the leaves with TMV protein earlier than 40 min before inoculation or 20 min after inoculation was without any influence on the number of lesions caused by TMV or TMV–RNA. The number of lesions was also not significantly different from the number of lesions on control half-leaves if a pre-inoculation with ovalbumin was used at any time-interval.

The increase of TMV and TMV–RNA infectivity caused by TMV protein rubbed on the leaves before the TMV or TMV–RNA inoculations makes it probable that the infectivity enhancement by TMV protein is at least in part result of TMV protein-induced changes in the tobacco leaves. In this connexion, the findings of Cochran *et al.*[7] are of interest in that they found TMV protein induces in tobacco leaf cells some specific changes which reflect themselves in the shift of the infra-red transmission spectra of the cell.

The enhancement of TMV infectivity by low, and the suppression of this infectivity by high, TMV protein concentration was caused by two different mechanisms. The suppression is probably the result of non-specific reversible adsorption of a part of the added protein to the surface of virus particles which inhibits the ability of these particles to attach at the infectible sites in the leaf cells. Different proteins from TMV protein also suppressed the infectivity of TMV. In this connexion it appears significant that TMV protein at the same concentration suppresses virus infectivity, but enhances TMV–RNA infectivity. The enhancement of the infectivity of both TMV and TMV–RNA by TMV protein is probably the result of an influence of this protein on the tobacco leaf cells, which resulted in creation of more favourable conditions for the initiation of infectivity. This enhancement is characteristic for TMV protein only and is not caused by other proteins.

A NEW CLASSIFICATION OF SEED PROTEINS: APPLICATION TO THE ALEURINS OF *Arachis hypogaea*

By DR. AARON M. ALTSCHUL, NAVIN J. NEUCERE, DR. ANTHONY A. WOODHAM[*] and DR. JOSEPH M. DECHARY

Seed Protein Pioneering Research Laboratory[†], New Orleans, Louisiana

THE early biochemists used the techniques of maceration and extraction to isolate the proteins of an organ. These proteins were catalogued according to their origin, and from these first investigations evolved more meaningful classifications based on the biological functions of the proteins or the structure with which they were associated. There is little to be gained, for example, in discussing liver or kidney or brain proteins. as compared to enzymes or specialized proteins of a tissue or organelle. There is, however, at least one outstanding example of a classical catalogue of proteins of an entire organ which has persisted virtually unchanged from the

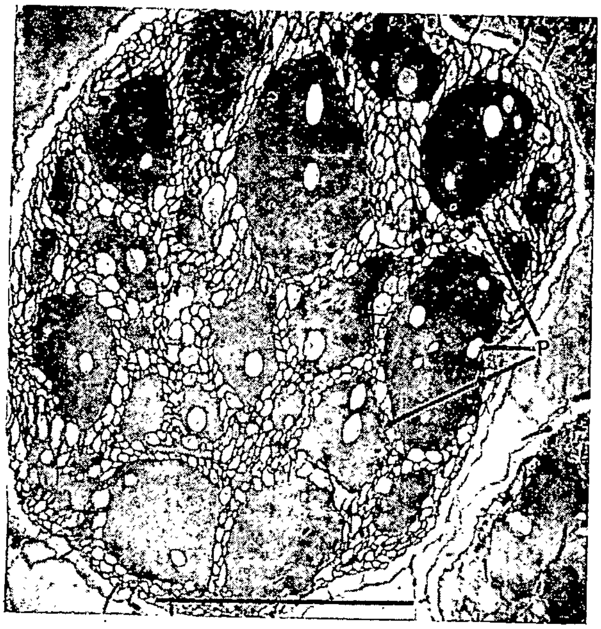

Fig. 1. Section of parenchyma cell of cotyledon of *Gossypium hirsutum* showing protein bodies (*P*). Bar, 10 mμ. Tissue fixed in $LiMnO_4$ and post-stained with lead citrate. (Courtesy of Dr. L. Y. Yatsu)

very beginning: the classification of seed proteins. A major portion of the mature seed is comprised of storage materials located either in the cotyledon or the endosperm. Most of the proteins of the seeds have been considered as storage proteins and have been classified on the basis of their solubility properties. Moreover, the major proteins are separated rather easily either by precipitation with acid or salts, by changing temperatures, or by crystallization[1,2].

It is now known that many of these proteins originally considered single entities are actually mixtures. Numerous examples are available of separation of these so-called pure species into several protein fractions by various techniques, such as chromatography or electrophoresis[3-8].

Moreover, the concept of solubility need not necessarily be fundamental to the protein, since associated materials or methods of obtaining the protein, or even the condition of the seed prior to extraction, have a profound influence on the solubility, as was shown, for example, by Stockwell *et al.*[9] for the solubility of edestin from hemp seed.

Obviously, as the reproductive structure of the plant, the seed has many proteins. It contains the biological machinery necessary for initiation of germination: mitochondria, plastids, and ribosomes, and their associated enzymes. A classification by an artificial criterion such as solubility does not provide a basis for selecting from the total proteins of the seed those which have their analogues in other tissues, plant or animal, and those which are unique to seeds.

A better approach to classification of seed proteins would be to use an element of uniqueness in seeds as the basis for categorization. It is now well established that much of the protein of seeds exists in so-called aleurone grains or protein bodies[3,10]. This is by no means a new observation. Protein bodies were described in the nineteenth century by Hartig[11] and Pfeffer[12], and were called aleurone grains by Hartig. These bodies vary from 2 to 20μ in diameter and, in general, vary in population density in the storage tissue in relation to its protein content. They were identified as containing protein by cytological staining. Their morphology is described better by the application of electron microscopy, and such techniques have been used to describe the following seeds: *Arachis hypogaea*[13], *Gossypium hirsutum*[3], *Glycine max*[14], *Pisum sativum*[15] and *Triticum aestivum*[16]. Fig. 1 is a photograph of typical protein bodies in a section of a cotyledon of a mature cotton seed (*Gossypium hirsutum*).

That these bodies do indeed contain protein was shown by Dieckert *et al.*[17], who isolated two types of protein-rich bodies from *Arachis hypogaea* seeds by a non-aqueous fractionation technique and showed that they contain 11 and 13 per cent nitrogen, respectively. They also showed that phytic acid is associated with the fraction containing 11 per cent nitrogen. By such a technique, however, they were unable to fractionate the proteins themselves; the DEAE–cellulose chromatograms of the protein of the particles as well as those of the total soluble proteins of the seed are similar. Varner and Schidlovsky[15] prepared a pellet from the cotyledons of *Pisum sativum* and showed by DEAE–cellulose chromatography that it contained the major fraction of the proteins of that seed. Morton and his colleagues showed that protein bodies isolated from the endosperm of immature *Triticum aestivum* contain the acid-soluble proteins of the wheat kernel[18].

We propose that those proteins contained within protein bodies or aleurone grains of seeds be named 'aleurins'. We chose this word because aleurone grains have been the classical name for the protein bodies in seeds. At this point, we are considering 'protein bodies' and 'aleurone grains' as synonymous terms. We conceive that each seed will have its aleurins; these will be identifiable and separable from the rest of the proteins. There is the possibility and likelihood that some aleurins of various seeds will have similar structure and function.

It may be that introduction of this classification will at the beginning change little of the present classification since many of the present techniques may have succeeded by chemical means in isolating mostly those proteins existing in protein bodies. But the isolation of proteins from an entire tissue suffers from the possibility that artefacts may have been produced by the admixture of the proteins with each other and with other tissue components; this possibility is minimized when the proteins are isolated from sub-cellular particles instead. There is also the possibility that several types of sub-cellular particles will occlude and be isolated together. As the separation procedures are refined, we may expect that some proteins originally classified as aleurins will fit better into other categories.

This approach to classification can be illustrated by considering the soluble proteins of the cotyledon of *Arachis hypogaea*.

The total soluble proteins of the peanut cotyledon have been categorized by Dechary *et al.*[19] into four groups based on their behaviour on chromatography on DEAE cellulose. An elution diagram of the total proteins is given in Fig. 2; in the same figure are shown the elution diagrams

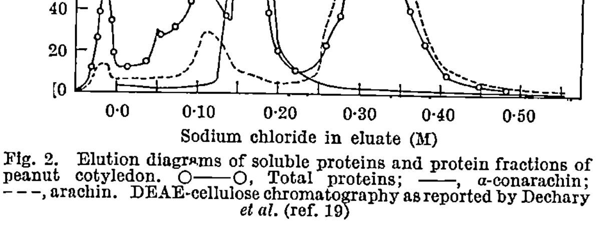

Fig. 2. Elution diagrams of soluble proteins and protein fractions of peanut cotyledon. ○——○, Total proteins; ——, α-conarachin; - - -, arachin. DEAE-cellulose chromatography as reported by Dechary *et al.* (ref. 19)

of classical arachin[1,2], and of α-conarachin isolated by Dechary *et al.*[19], by preparative DEAE chromatography. Altschul *et al.*[20] showed that approximately 75 per cent of the total proteins of this seed were not solubilized in neutral buffer containing 'Carbowax'* and that some of them were not solubilized in the presence of 0·25 M sucrose. This procedure provided the basis for the isolation of proteins from particles and their comparison to the total proteins and to the fractions shown in Fig. 2.

The protein bodies of the peanut cotyledon are fragile and particularly sensitive to the ionic strength of the buffer. The first attempt to isolate these particles involved maceration in 0·05 M phosphate buffer, *p*H 7, 0·25 M in sucrose. After removal of the debris and starch grains at 1,000*g* centrifugation, the supernatant was refrigerated overnight; the protein bodies which sedimented at 100*g* contained only 3·5 per cent nitrogen. In a second attempt, an unbuffered 0·25 M sucrose solution was used. After removal of starch grains and debris at 100*g*, the protein body fraction was isolated by centrifuging at 10,000*g* for 10 min; after further purification a sample containing 10·7 per cent nitrogen was obtained. The proteins of the particles were dissolved in buffer at *p*H 8. The elution pattern of DEAE chromatography typical of the soluble particle proteins is shown in Fig. 3; note the resemblance between this pattern and the arachin fraction of Fig. 2.

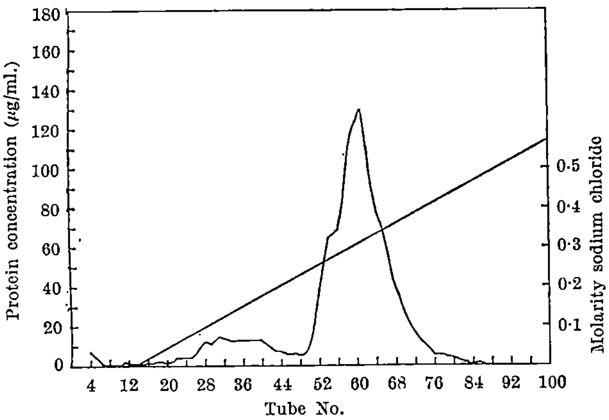

Fig. 3. Elution pattern of particulate fraction stable in 0·25 M sucrose. Chromatography on DEAE-cellulose as described for Fig. 2. The straight line is the sodium chloride gradient as measured in the eluate

In the major peak of the chromatogram of the particulate fraction (Fig. 3) there is evidence of a shoulder eluted at about 0·26–0·29 M sodium chloride. Therefore, it was of interest to determine whether density gradient centrifugation would separate the pellet into several fractions. Density gradient centrifugation did indeed enrich the material eluted at 0·26–0·29 M sodium chloride: the heavier material gave a pattern similar to that shown in Fig. 3; the lighter material showed almost an equal amount of the material eluted at 0·26–0·29 M sodium chloride and at 0·32–0·34 M sodium chloride, respectively. It was found, however, that better separation was obtained by taking advantage of the relative stability of portions of these particulates to slightly higher *p*H. In this manner two fractions were obtained: a heavy fraction and a fraction stable at *p*H 6 which contained primarily the proteins with the elution peak at 0·26–0·29 M sodium chloride. The elution patterns for these two fractions are shown in Fig. 4; the *p*H 6 fraction is predominantly the shoulder seen in the other fraction.

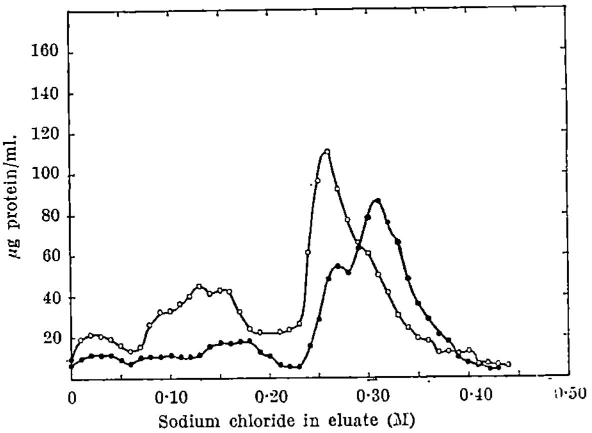

Fig. 4. Fractionation of particulate proteins of peanut cotyledon. Chromatography on DEAE-cellulose as described for Fig. 2. ●, Denotes the heavy fraction which was obtained as follows: cotyledons were macerated in 0·05 M citrate buffer, *p*H 5, 0·25 M in sucrose and 0·005 M in sodium ethylenediamine tetraacetic acid (EDTA). (The inclusion of EDTA increased the yield and reduced the clumping of particles.) The debris, nuclei, and starch grains were removed by centrifugation at 500*g* for 30 sec. The pellet obtained by centrifuging the supernatant at 1,000*g* for 10 min was resuspended in the same solvent, re-homogenized, and brought down at 500*g* for 10 min. This pellet was layered over 1·8 M sucrose in the same buffer and centrifuged at 125*g* for 20 min. the material at the interface was removed and collected by centrifugation at 11,500*g*. ○, Denotes the *p*H 6-stable fraction prepared as follows: The cotyledons were macerated as described above. After removal of debris and heavy particles, the supernatant was collected at 5,000*g* and resuspended in 0·25 M sucrose containing 0·005 M EDTA adjusted to *p*H 6 with NaOH. This was stored for 18 h at 4° C, collected at 5,000*g* for 20 min and washed several times

After dialysis against distilled water, the fractions were dried and analysed for protein, phosphorus, and lipid content; fresh samples were also tested for phosphatase activity with ATP as a substrate. The results are given in Table 1. Both fractions have a high protein content and some phosphorus; the *p*H 6 fraction contains more lipid and has more phosphatase activity. It will be recalled that Yatsu and Altschul[21] recovered particles from the cottonseed cotyledon which contained 25–29 per cent lipids.

The sedimentation patterns of both fractions in phosphate buffer (*p*H 7·9, μ = 0·03) are given in Fig. 5. The major peak has a sedimentation coefficient, S_0, of 9,

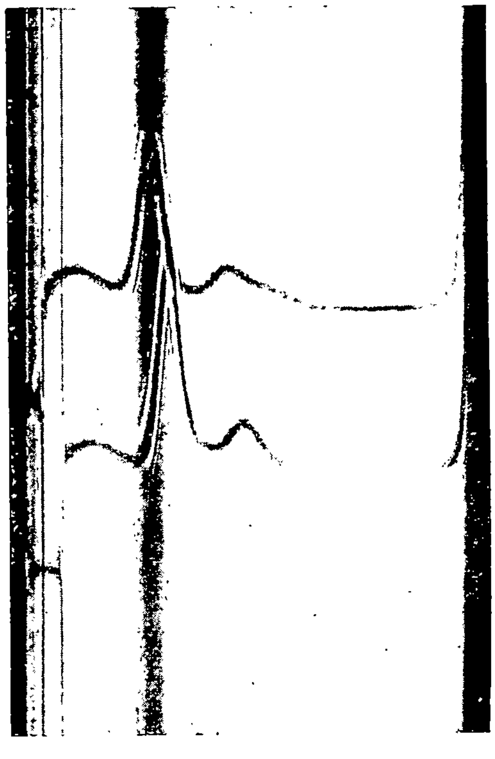

Fig. 5. Sedimentation patterns of *p*H 6 stable particle (upper pattern) and heavy particle in 0·03 M phosphate buffer, *p*H 7·9, 24 min after top speed at 59,780 r.p.m. (Analyses performed by W. B. Carney)

---

* Mention of trade names does not imply recommendation of the particular product over others which may be equally suitable.

Table 1. COMPOSITION OF TWO PARTICULATE FRACTIONS FROM COTYLEDONS OF *Arachis hypogaea*

Fraction	Protein %	Total phosphorous %	Lipid %	ATPase
Heavy particle	56	0·35	8	0·17
*p*H 6 particle	55	0·40	45	0·45

Protein was determined by the method of Lowry *et al*, (ref. 24), total phosphorus by acid digestion followed by assay for inorganic phosphate by the Technicon modification of the Fiske–Subbarow method (*Technicon Manual*, 1958). The ethyl ether–extractable material is reported as lipid; ATPase analyses were by Dr. H. D. Brown; enzyme activity is reported as mg inorganic phosphate produced in 2 h per mg protein (ref. 25).

which is identical with that given by Johnson and Shooter[22] for the monomer of arachin. It is interesting to note that Johnson and Shooter, who used high salt concentrations to isolate arachin, obtained predominantly the dimer; this particular method of isolation produces predominantly the monomer. Both samples were also examined by gel-electrophoresis and gave essentially the same patterns which showed three major components. Here is an instance where two fractions differ in their behaviour by DEAE column chromatography but are similar both by ultracentrifugation and gel electrophoresis. Moreover, the particles differ considerably both in enzyme activity and in lipid content. We may be dealing here with allomorphic forms of the major components, or perhaps proteins which differ slightly in amide content. This matter is being investigated further; the morphological significance of the fractionation is also being investigated.

The aleurins of *Arachis hypogaea* comprise primarily those proteins of group IV according to Dechary *et al.*[19]. Apparently α-conarachin is not contained in these particles and, therefore, on the basis of this evidence is not an aleurin. It is interesting to note that with the same system of DEAE chromatographic analysis, the aleurins of the pea, *Pisum sativum*, have the same chromatographic properties as the aleurins of the peanut[15]. The only other instance known of particles from protein bodies having been isolated and characterized are those in the immature wheat endosperm[18]: the aleurins of wheat would be the acid-soluble proteins of the endosperm.

There is phosphatase activity in the particles and no doubt other enzyme activities are either a part of the particles or are occluded to them during the process of isolation. We known that the particles undergo well-defined alterations on germination[13]. What proportion of these are induced by enzymes existing within the particles, by some produced *de novo* within the particles, or by exogenous enzymes, is not known. We also know from the work of Morton and Raison[23] that the particles contain systems for deriving energy from phytates and for synthesizing the particle proteins themselves. Therefore, there is every reason to believe that the particles as they exist in the resting seed are not entirely inert. By investigating further the properties of the particles it may turn out that biological activities will be found for many of the proteins contained therein.

EFFECTS OF GROWTH-REGULATING SUBSTANCES ON INULIN-STORING PLANT TISSUES

By PROF. R. L. WAIN, F.R.S., P. P. RUTHERFORD, E. W. WESTON and C. M. GRIFFITHS

Wye College (University of London), Near Ashford, Kent

REINDERS[1,2] was the first to establish that the uptake of water by plant storage tissues was promoted by the application of growth substances such as indolyl-3-acetic acid. This and related effects have since been investigated by various workers, attention having been directed both to changes in cell walls[3–6] and cell constituents[7,8].

The effects of growth-regulating substances on water uptake[9–11], rate of respiration[12,13] and protein synthesis[14] have been found to be greater for disks of Jerusalem artichoke than for other storage tissues. Jerusalem artichoke was one of the few plants examined which stores inulin. We have confirmed the marked effect of growth substances in promoting water uptake[2] and increasing the rate of respiration[12,13] of this tissue and have found even greater responses to occur with tissues from other inulin-storing plants such as chicory. The marked effect of 2 : 4-dichlorophenoxyacetic acid (2 : 4-D) in promoting water uptake in disks of Jerusalem artichoke and chicory is shown in Table 1 and chicory in Fig. 1. We have examined a wide range of compounds in this way, including aryl- and aryloxyalkane-carboxylic acids, and the chemical structure in relation to this type of biological activity has been investigated. With phenoxyacetic acids the effects of nuclear and side-chain substitution on activity were similar to those found previously using other

tests for plant growth-regulating activity[15]; thus, for example, 2 : 4-D is highly active, whereas 3 : 5-dichlorophenoxyacetic acid (3 : 5-D) is inactive. These aspects of our work will be published elsewhere.

As early as 1935 Czaja[16] suggested that auxins promoted extension growth by inducing increased osmotic pressure of the cell sap. Later osmotic pressure determinations[8] on the liquid expressed from disks of potato tubers indicated that auxin treatment does not appreciably change the number of osmotically active molecules present, but the increased rate of respiration induced by treatment indicated that changes in carbohydrate had occurred. Although there is evidence[17] that auxins do not appreciably affect amylase activity, it is possible that they may influence the enzymes present in inulin-storing tissues[18]. We have examined this possibility by following the changes in carbohydrate occurring within the storage tissues of chicory and artichoke.

Continuous extraction of the tissue slices under reflux with 80 per cent ethanol was used to separate the carbohydrates into soluble (less than about 10 hexose units) and insoluble fractions. The soluble carbohydrates were further fractionated into reducing and non-reducing sugars, the former having been shown to consist solely of glucose and fructose[19]. These reducing sugars were determined directly by the method of Somogyi[20] and the non-reducing and insoluble fractions were estimated by the same method after acid hydrolysis. The individual soluble sugars were separated by paper partition chromatography, eluted and determined in a similar manner. Detailed results will be published elsewhere.

The proportion of carbohydrate in the dry matter was found to decrease during incubation and this loss was much greater in the 2 : 4-D-treated tissue. For artichoke, treatment with water or the inactive growth substance 3 : 5-D (10^{-5} M) for six days lowered the total carbohydrate content by some 25 per cent: 2 : 4-D at 10^{-5} M, on the other hand, caused a corresponding decrease of about 70 per cent.

Such differences are explicable in terms of the increase of the rate of respiration which we observed to be about three times greater than the control in artichoke disks treated with 2 : 4-D.

The amount of insoluble carbohydrate present in the artichoke tissue, comprising about 4 per cent of the dry matter, was not significantly affected by treatment with growth substance or water, and the overall decrease in total carbohydrate arising from the increased rate of respiration is accounted for by a decrease in the amount of certain soluble sugars present. Chromatographic examination of changes in individual sugars showed that the 2 : 4-D treatment caused a progressive decrease of the amount of

4	0·160	0·074	0·157
6	0·188	0·086	0·179

tri- and higher soluble polysaccharides; sucrose after an initial fall remained constant, while there was a considerable increase in glucose and fructose. In artichoke these reducing sugars increased from about 1 to 8 per cent. In untreated tissue and that treated by the inactive growth substance, 3 : 5-D, there was a slight fall in the levels of all sugars. The effect of 2 : 4-D on the breakdown of fructosans present in Jerusalem artichoke is shown in Fig. 2.

Within the first 48 h of cutting, the molar concentration of soluble sugars in tissue slices cut from Jerusalem artichoke decreased regardless of whether they had been treated with 2 : 4-D, water or 3 : 5-D. However, this decrease was much greater for 2 : 4-D-treated tissue (Table 2). Thereafter the total molar concentration of soluble sugars remained constant in spite of considerable changes in individual sugars, respiration and water uptake. For 2 : 4-D-treated tissue this was achieved by the breakdown of oligosaccharides, resulting in an increase of glucose and fructose (Fig. 3).

The results here reported clearly indicate an important effect of 2 : 4-D in promoting the hydrolysis of fructose oligosaccharides present in certain storage tissues and are consistent with the view that during most of the period in which water is taken into the tissue sugars are involved in some kind of osmotic regulation. Attempts are now being made to isolate the system which controls the hydrolysis of fructose oligosaccharides in this tissue so that the influence of growth substances on its activity can be fully investigated.

PHYSIOLOGICAL AND GENETIC EFFECTS OF 8-AZAGUANINE ON *Aspergillus nidulans*

By Dr. A. T. BULL and Dr. B. M. FAULKNER

Department of Botany, Bedford College, University of London

PURINE and pyrimidine base analogues have been reported as having a variety of physiological effects in angiosperms[1,7], algae[2], ferns[3], fungi[4,8–10,13], bacteria[5,14] and viruses[6]. The majority of investigations have been concerned with the effect of base analogues on growth and the biosynthesis of nucleic acids and proteins, and comparatively little information is available on heritable changes induced by these antimetabolites. Action of the analogue may involve the synthesis of analogue-containing nucleic acids or fraudulent nucleotide derivatives. Consideration of the following areas of metabolism would appear profitable in this context: (1) inhibition of nucleotide synthesis creating a base deficiency; (2) incorporation of analogue nucleotides producing fraudulent nucleic acids; (3) imbalanced nucleic acid synthesis due to stimulation, or inhibition of certain enzymes, for example, xanthine oxidase inhibition causing a decrease in normal purine catabolism; (4) impaired protein synthesis due to, say, availability of guanosine di- or tri-phosphates. The present programme was initiated with the aim of determining the nature of 8-azaguanine activity and correlating this with any induced genetic effects.

Two stable, haploid, homocaryotic strains (13 and 13*y*) of an ascosporic *Aspergillus nidulans* stock, producing green and yellow conidia respectively, were treated with 8-azaguanine (8-AG) over the concentration range 10^{-8}–10^{-2} molar in liquid Czapek minimal medium. The *p*H of the medium was not adjusted. The analogue was dissolved in a minimal volume of sodium carbonate (0·5 per cent w/v) before addition to the medium. Using standard spore inocula, cultures were set up in 30 ml. aliquots of media contained in 100 ml. Erlenmeyer flasks and incubated at 25° ± 0·5° C on a reciprocal shaking machine. Growth was measured by collecting the mycelia on tarred sintered glass filters, oven drying at 100° C for 24 h, then re-weighing. Measurements were made in triplicate, and growth expressed as mg dry weight of mycelium per flask. Unsupplemented control cultures were run with each experiment.

Both strains had similar growth characteristics in minimal medium: 13*y* showed a slightly higher logarithmic growth rate (2·15 mg dry wt./h) and shorter lag phase (60 h) than 13 (1·95 mg dry wt./h and 61·5 h respectively). After 22 days' incubation each strain had produced approximately 350 mg dry wt. of mycelium per flask; afterwards autolysis commenced. Similarly both strains showed a common response to 8-AG and results from a typical experiment are given in Table 1.

High concentrations of 8-AG (10^{-2} and 10^{-4} M) inhibited growth, whereas lower molarities had a stimulatory effect. The initial enhanced growth rate was due to increased germ tube production—conidia in minimal medium germinated via a single (occasionally two) germ tube, while two or three germ tubes developed in the presence of the

Table 1. EFFECT OF 8-AZAGUANINE ON THE GROWTH* OF *Aspergillus nidulans*

* Expressed as percentage of unsupplemented control (control = 100).

analogue. Subsequent decrease in growth rate (cf. data for 72 h) in the majority of treatments was the result of retarded sporulation; thereafter growth in supplemented media was stimulated until the onset of senescence. In the presence of 10^{-2} M 8-AG growth never exceeded 30–40 per cent of the controls and hyphal morphology was abnormal compared with development in all other cases. Normal hyphal cells were rectangular, had homogeneous contents and measured 2–3 × 20μ. The 10^{-2} M 8-AG induced irregular cell division and growth, cell shape varying from spherical, oval to isodiametrical and size from 6 × 5μ to 7·5 × 8μ with frequent swelling of the hyphæ to 12μ in diameter. The contents of such cells appeared granular and/or vacuolated in stained and viable preparations. The analogue frequently induced a growth form reminiscent of the pseudomycelia of certain yeasts. Similar abnormal development has been observed in wild-type *Aspergillus glaucus* when the fungus was grown on solid media containing 8-AG (Bull and Johns, M., unpublished data); certain hyphæ grew in advance of the colony front and, while cell elongation was strikingly inhibited, cell division and branching were stimulated, thereby producing 'star-shaped' mycelia and whorls of short, swollen hyphæ.

The inhibitory effect of 8-AG was reversed by normal purine bases; results are shown in Table 2.

Table 2. EFFECT OF PURINE BASES ON 8-AG INHIBITION DURING THE LOGARITHMIC GROWTH PHASE*

Guanine	42	95	77	154
Uric acid	26	80	24	108
Xanthine	15	88	27	99

* Expressed as percentage of unsupplemented control (control = 100).

All the purines inhibited growth at high concentrations except in strain 13*y* where the 10^{-4} M treatments were stimulatory. The fact that 8-AG relieved the inhibition induced by supra-optimal concentrations of adenine, guanine and xanthine in strain 13 suggests that the analogue can act by reducing the physiological level of these purines. This response is similar to that found in the imperfect fungus *Diplodia natalensis*[8], where it has been suggested that adenine and guanine are interconvertible since the growth inhibition of antipurines is reversed in the presence of either normal base. A contrary situation has been demonstrated in biochemical mutants of *Neurospora*[9] and *Ophiostoma*[10]. The effects of the di- and trihydroxypurines are difficult to interpret at this stage. These bases are normally encountered as products of adenine and guanine degradation. The absence of high xanthine oxidase activity in these strains of *Aspergillus* would make available xanthine for adenine and/or guanine synthesis as in rabbit bone marrow[11] and rat[12], whereas a high enzyme activity would suggest non-specific competition of the hydroxypurines with 8-AG. 8-Azaguanine inhibition in other genetically characterized strains of *A. nidulans* is completely removed by adenine and guanine but not by xanthine[13]; in contrast, hypoxanthine releases 8-AG growth inhibition in *Bacillus cereus*[14]. The potentiating effect of uric acid on 8-AG inhibition may be due to the inhibition of analogue deamination.

After growth for 24–432 h in liquid Czapek minimal medium containing 8-AG both strains were screened for morphological variants. Samples of mycelia were transferred to solid Czapek minimal medium and their subsequent growth observed for the occurrence of morphological variation. The variants isolated constituted either the whole of the growth, or arose as sectors from apparently wild-type mycelium. No variants were obtained from control cultures. Table 4 shows the variants isolated from liquid cultures of different ages in two experiments. Each sample of mycelium was taken from a separate culture.

Table 4. VARIANTS* OF *A. nidulans* ISOLATED ON SOLID CZAPEK MINIMAL MEDIUM FOLLOWING TREATMENT WITH 8-AG IN LIQUID CULTURE

		Strain 13				Strain 13*y*

	432	1	1	1	2		1		1*a*

* Variant 1: pink, fluffy mycelium; cleistothecia ('perithecia' of common genetical usage) bearing Hülle cells which autolyse; pink pigment secreted into medium. Variant 1*a*: as variant 1 but Hülle cells normal.

Variant 2: cleistothecia absent; little extracellular pigment compared with wild type.

Variant 3: mycelium covered with web of aerial hyphæ; reduced production of cleistothecia; red-pink pigment produced extracellularly.

Variant 4: increased production of cleistothecia; few conidial heads; little extracellular pigmentation compared with wild type.

The asexual spore progeny of all isolates of each variant was examined. All the isolated 1 and 2 variants bred true except one obtained after 432 h in 10^{-6} M 8-AG (strain 13, Exp. 1). The latter gave both sexual and asexual colonies among its asexual spore progeny. The asexual spore progenies from variants 3 and 4 contained a number of phenotypic classes. The two isolates of variant 4 from strain 13*y* gave rise to different phenotypic classes among their asexual offspring. In subsequent asexual spore progenies all the isolates of variants 3 and 4 have produced yet further phenotypic classes, some of which bred true, but the majority of which again segregated among their asexual offspring. So far only the sexual variant 1 isolates have been screened by Jinks's[15,16] heterocaryon test. All these isolates proved to be nuclear in origin. The continuously segregating isolates of variants 3 and 4 obtained from strain 13*y*, which was known to have uninucleate, haploid asexual spores[17], are prospectively cytoplasmic in origin[18]. The results in Table 4 suggest that 8-AG may act specifically in the production of genetic variation, and the behaviour of the variants suggests that the sites of activity of the analogue may be both nuclear and extranuclear.

Work is continuing to determine the metabolic fate of 8-azaguanine in this micro-organism and to establish more precisely the genetic nature of the variants.

LETTERS TO THE EDITOR

GEOPHYSICS

Laser Radar Echoes from the Clear Atmosphere

Using experimental pulsed ruby laser radars, numerous observations have been made here of echoes from the 'clear' atmosphere. There is no doubt that these returns are caused by backscattering from particulate matter in the aerosol. Even in the clearest conditions echoes are invariably obtained from the immediate vicinity, and these are much enhanced in hazy conditions. Strong signals are commonly noted at heights corresponding to low-level inversions, revealing haze layers which are not discernible by eye.

A particularly interesting series of observations was made on August 19, 1963. These observations were made with an early version of our laser radar having the characteristics given in Table 1. They were made by pointing the radar at an elevation of 15° (on a bearing of 036° T) in the direction of San Francisco Bay, which is some 2·5 nautical miles distant from the laboratory. Although very slight haze had been present in the morning, the afternoon of August 19, 1963, was bright and clear, with blue skies and unrestricted visibility (more than 8 nautical miles). A northerly sea breeze, which was estimated at 5–10 knots in the late forenoon, had freshened to 10–15 knots by the time of observation (1430 P.S.T.). Fig. 1 shows a plot of relative signal intensity versus range for three successive observations made over a period of some 12 min. Log/log co-ordinates have been used to facilitate interpretation. On these co-ordinates a plot of signals from a non-attenuating medium would be a straight line having a slope determined by range.

Fig. 1*a* thus shows an instantaneous, direct observation of discontinuities in clear air which was in motion. We believe that the variations in signal intensity were due to variations in the particulate matter content, and hence in the backscattering characteristics of two or more intermixing aerosols. Figs. 1*b* and *c* show the changes which occurred with time as mixing proceeded or as more homogeneous air passed into the area. A number of other observations made on August 19, 1963, before the series illustrated, showed similar discontinuities fluctuating with time. For comparison, Fig. 1*d* shows returns made in very similar apparent conditions on the following afternoon, August 20, when the aerosol was consistently homogeneous.

Table 1. *SRI* Lidar *Mark I* (1963)

Laser	3 in. × 1/4 in., 90° *C*-axis ruby crystal, transparent and semi-reflecting coatings on flat ends. *Q*-switched	Receiver	10 stage RCA photo-multiplier type 7326
Pulse length	24 n sec	Aperture	4 in. diam.
Peak power	5 MW	Bandpass	Approx. 20 Å
Beam width	0·5°		

The implication of these early observations is very far-reaching. Particulate matter is present in some degree throughout the atmosphere. The possibility of mapping the effects of air motion, and in particular that associated with 'clear air turbulence' by reference to laser radar returns from particulate matter, thus appears to be realistic. Although considerable technological development will be needed and also a better understanding of the nature of clear air turbulence it is suggested this approach to the detection of clear air turbulence is more promising than any based on obtaining optical echoes from variations in the gaseous state of the atmosphere.

Magnetic Disturbances preceding the 1964 Alaska Earthquake

Through a fortunate circumstance, a recording magnetometer was operating in the city of Kodiak, 30 km north-west of the surface trace of a fault zone along which movement occurred at the time when the earthquake occurred in Alaska on March 27, 1964. Fortunately, too, the instrument was on such high ground that it was not reached by the subsequent seismic sea wave which virtually destroyed the city. The magnetometer recorded the fact that the largest of several magnetic

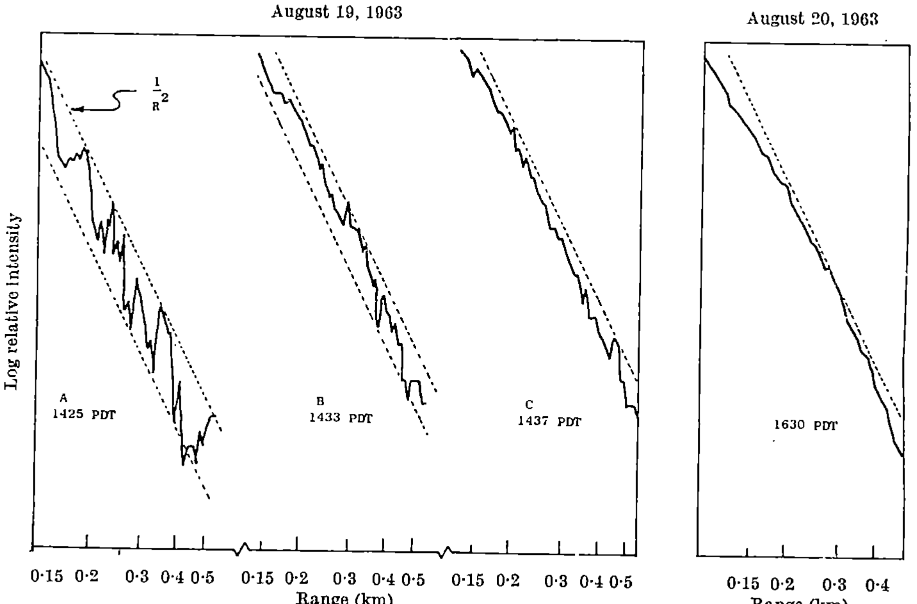

Fig. 1. Clear air observations. *SRI* ruby laser radar (*Mark I*). Bright clear afternoons with good visibility and moderate northerly and easterly winds. Azimuth 36°, elevation 15°

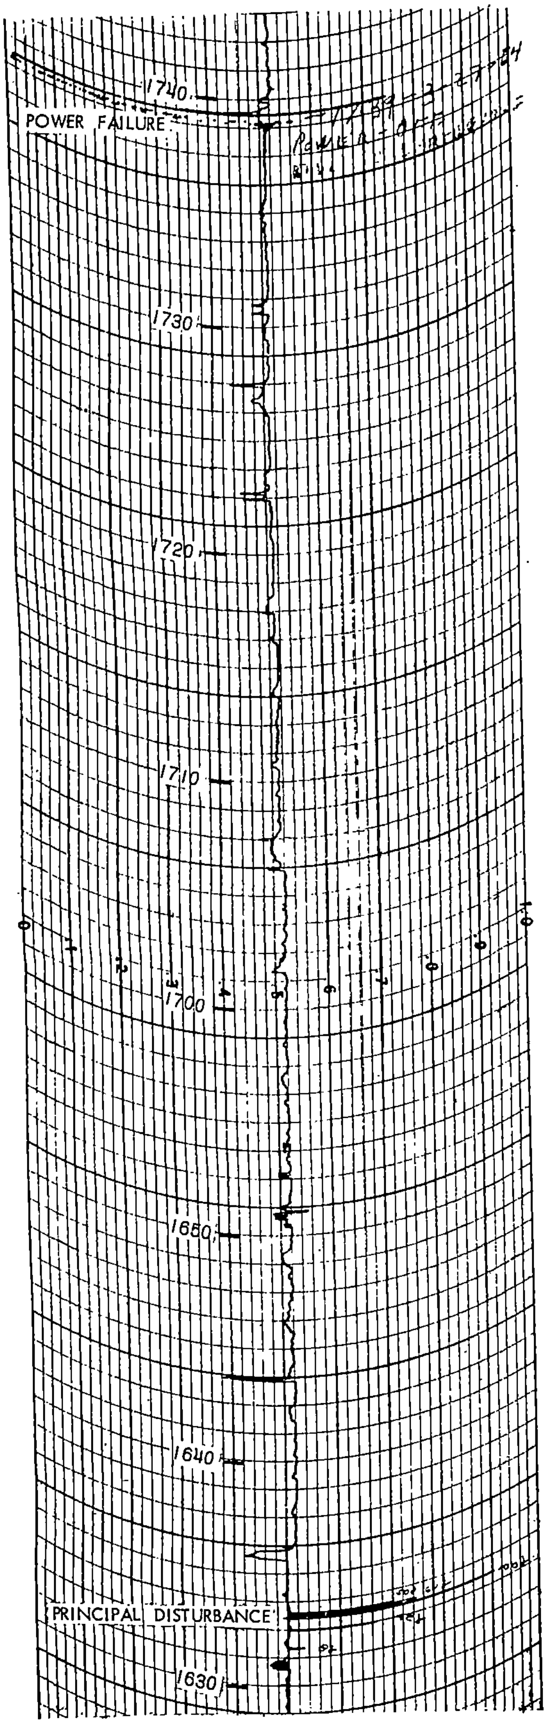

Fig. 1. Record of the positive magnetic disturbances which preceded the Alaska earthquake. Heavy time divisions equal 7·5 min. Time is Alaaks Standard Time, March 27, 1964. Full scale for the magnetic intensity, which increases toward the right, is 250 gammas

disturbances briefly increased the intensity of the Earth's magnetic field by 100γ at Kodiak, 1 h 6 min before the earthquake (Fig. 1).

The magnetometer had been installed for the Superior Oil Co. and the Pan American Petroleum Corp. by Fairchild Aerial Surveys to serve as a ground monitor for an airborne magnetic survey being made of the region. The instrument is a Gulf flux-gate magnetometer, which records the total magnetic field intensity on an Esterline Angus recorder. The sensing element had been installed on the grounds of the Bay Shore Motel in Kodiak.

The record was stopped at the beginning of the earthquake by a massive short circuit in the city power system. Automatic equipment in the Kodiak power plant made four unsuccessful attempts, in a period of about 3 sec, to reclose the circuits, and then cut off the power indefinitely[1]. Because Fairchild lost their aeroplane and one member of their team in the disaster, the magnetometer was disconnected and put in storage before the city power was turned on again. The trace that follows the record of the power failure on Fig. 1 was made approximately a month later, when the survey was resumed.

An electric clock which ran on city power in the room with the recorder stopped at 1739 Alaska Standard Time, March 27, 1964. This time reference has an estimated precision of ± 1 min (ref. 2), and according to it, the principal magnetic event occurred at 1633 A.S.T. The official time for the earthquake at its focus, 440 km to the north-east, was 1736.2 A.S.T. (0336.2 G.M.T., March 28).

The chart shows many small negative magnetic disturbances that were caused by automobiles passing on a road about 15 m south-east of the sensing element. The positive disturbances, however, which are believed to have been associated with the earthquake, began at 1632 A.S.T. with three sharp events extending over a period of about a minute, and culminated in a positive disturbance equal to 100γ. This was immediately followed by two somewhat smaller events, and a still smaller one occurred 18 min later. No other sharp positive disturbances were found on about a month of record.

One possibility is that the magnetic events which preceded the Alaska earthquake resulted from piezomagnetic effects of rocks undergoing a change in stress[3]. Why such abrupt disturbances occurred in advance of the earthquake is not known; but a causal relation is indicated by the fact that Breiner[4] has recently reported similar positive magnetic disturbances prior to minor earthquakes in Nevada and California. These observations, taken together, suggest that magnetic monitoring may provide a means of predicting a major earthquake in time to save lives and property.

Jon W. Davidson, of the Superior Oil Co., contributed to this report in helpful discussions. I thank the Superior Oil Co. for its co-operation, the Pan American Petroleum Corp., and Fairchild Aerial Surveys in permitting the release of the information. Publication was authorized by the Director, U.S. Geological Survey[5].

GEOLOGY

Age of Labrador Anorthosites

THE age of the Nain anorthosite[1,2] on the coast of Newfoundland–Labrador is probably the same as that of the Michikamau anorthosite (1,400 ± 80 m.y.) recently reported by Emslie[3]. The Nain anorthosite is flanked on the north side by the Kiglapait layered intrusion[4,5], which shows no chill against anorthosite and is therefore thought to be barely younger than the anorthosite. The Kiglapait intrusion is invaded on its north margin by a granodiorite, possibly rheomorphic, the biotite of which gives a potassium-argon age[6] of 1,480 ± 50 m.y. This is therefore a minimum age for the Kiglapait intrusion, and also for the anorthosite.

Dikes and small stocks of subsolvus Manvers granite[5] cut the Kiglapait intrusion and anorthosite in the vicinity of Port Manvers. This granite tends to occupy flat-lying sheet joints in the Kiglapait intrusion, and is tectonically distinctly younger than the more concordant granodiorite. Its biotite gives a potassium–argon age[6] of 1,140 ± 40 m.y. The granodiorite may be equivalent to earlier stages of Wheeler's adamellite[7], and the Manvers granite may be equivalent to his later biotite facies adamellite. However, tectonically and petrographically similar granites occur up and down the coast of Labrador, so any meaningful correlation of these younger granites with adamellite will have to await further isotope age studies.

The age equivalence of the Nain and Michikamau anorthosites gives further support to the view of Emslie that these bodies in the Nain Province[8] record the true age of anorthosite emplacement in eastern North America, and that this event preceded the widespread metamorphic effects of the Grenville orogeny (950 m.y. as recently defined)[8]. Geological evidence that the Labrador anorthosites were less affected by metamorphism is mentioned by Kranck[1] as well as by Emslie. A pre-Grenville age of anorthosite emplacement in the Adirondack highlands is indicated by the stratigraphic and structural work of Walton and De Waard[9].

Progressive Desilication of Basic Hornfelses

The progressive desilication of pelitic sediments during contact metamorphism has been known for some time[1,2]. A mineral assemblage relatively enriched in aluminium and impoverished in silicon is progressively developed with the production of such phases as spinel, corundum, enstatite, cordierite and andalusite. The initial silica content of an argillaceous sediment before metamorphism may be between 60 and 70 per cent and on contact metamorphism desilication may lower the silica value to about 45–55 per cent—a range found in some pelitic xenoliths enclosed in granite.

A similar process for basic rocks, not previously recorded, is proposed for the basic hornfelses of the Land's End granite aureole, Cornwall. Although the process involves progressive desilication, it is not strictly analogous to that seen in pelitic hornfelses as the basic hornfelses have little or no free silica as quartz and are the products of progressive additive metasomatism.

On contact metamorphism, the basic intrusives ('greenstones') of the Land's End aureole were metamorphosed to hornblende hornfelses. The allochemical addition of potassium to these rocks produced biotite-rich hornfelses or potassium-hornfelses[3,4]. Localized internal metasomatism of the hornblende hornfelses produced iron–magnesium-hornfelses[5–7] containing anthophyllite, cummingtonite and cordierite and also calcium-hornfelses[8] containing sphene, diopside, grossularite, epidote and calcite.

Two distinct desilication trends can be traced in the basic hornfelses.

The first trend is very limited in extent and concerns the hornblende hornfelses. In a few instances spinel has been found in plagioclase-hornblende hornfelses, but no other silica-poor minerals[9]. On the production of a cordierite-anthophyllite assemblage from the plagioclase-hornblende hornfels there may be some loss of silicon, although this is by no means always the case. However, marked desilication is represented when the iron–magnesium-hornfelses have developed such minerals as diaspore and spinel[5]. Such an assemblage can be considered the silica-poor equivalent of the plagioclase-hornblende or cordierite-anthophyllite assemblage (Table 1).

Table 1. Comparative Analyses of Basic Hornfelses from the Land's End Aureole, Cornwall

	1	2	3	4	5
SiO_2	44·37	49·10	48·87	47·40	33·58

CO_2	0·03	—	0·07	0·01	0·00
Total	100·06	99·97	99·80	99·93	99·76

1 Plagioclase-hornblende hornfels, Tater-du (ref. 4).
2 Plagioclase-hornblende hornfels, Botallack (ref. 5).
3 Plagioclase-cordierite-cummingtonite-anthophyllite hornfels, Kenidjack (ref. 5).
4 Plagioclase-biotite-cummingtonite-anthophyllite hornfels, Tater-du (ref. 4).
5 Cordierite-anthophyllite-diaspore-spinel hornfels, Kenidjack (ref. 5).

The second trend involves progressive desilication during the extensive calcium metasomatism of the hornblende hornfelses. During the internal iron–magnesium metasomatism of the hornblende hornfelses, large quantities of calcium were released which effected metasomatism elsewhere[8]. The hornblende hornfelses invaded by the migrating calcium were progressively replaced by assemblages rich in calcium-bearing minerals, namely, ilmenite-sphene-diopside-hornblende, sphene-diopside-grossularite-hornblende, grossularite-clinozoisite

Table 2. Comparative Analyses of Calcium-Hornfelses from the Land's End Aureole, Cornwall

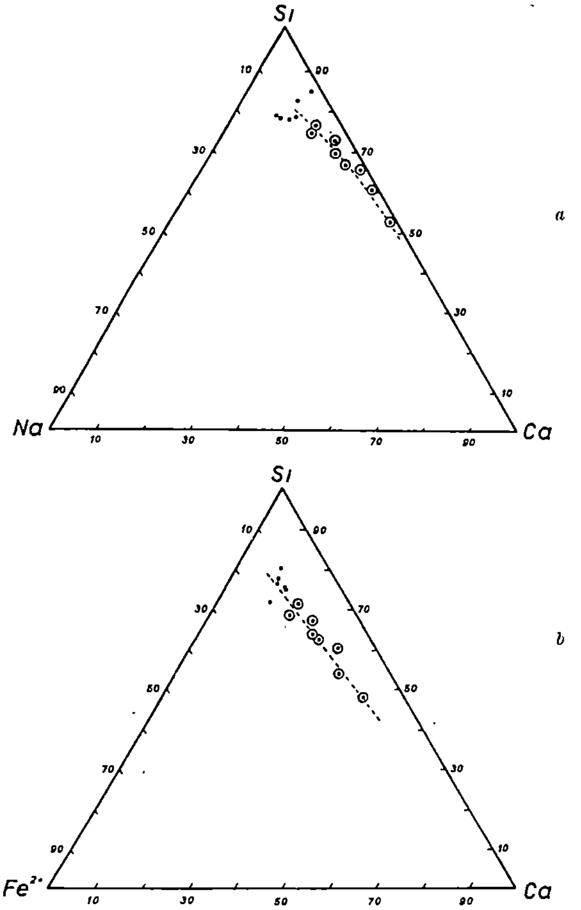
Total	100·05	99·58	99·47	100·28	100·06*

* Total includes 2·01 per cent B_2O_3.

1 Unmetasomatized plagioclase-hornblende hornfels parent (average of analyses 1 and 2 from Table 1).
2 Hornblende-diopside-biotite-sphene hornfels, Tater-du (ref. 4).
3 Hornblende-diopside-sphene hornfels, Tater-du (ref. 4).
4 Diopside-grossularite-sphene hornfels, Tater-du (ref. 4).
5 Calcite-diopside-grossularite-sphene-axinite hornfels, Tater-du (ref. 4).

and clinozoisite-zoisite-calcite-axinite. Table 2 shows the major-element chemistry of some of the calcium-hornfelses from Tater-du, Land's End peninsula.

Figs. 1*a* and 1*b* show the antipathetic relationship of silicon and calcium for hornblende hornfelses and calcium-hornfelses (those with more than 15 calcium cations per unit cell of 160 oxygens). The trend is towards calcium enrichment, as later calcium minerals are seen to replace earlier, and also progressive desilication of the hornblende hornfelses.



Figs. 1*a* and *b*. Triangular variation diagrams showing the antipathetic relationship between calcium and silicon for hornblende hornfelses and calcium-hornfelses from the Land's End aureole, Cornwall. ●, Hornblende hornfelses; ⊙, calcium-hornfelses

It is rare in reports of metasomatic processes for the subtracted materials to be accounted for; however, in the present case, the silicon, which represents a major subtracted migrant, can probably be traced. At the Avarak, on the north-west coast of the Land's End peninsula, there is a localized area of siliceous and felspathic hornfelses, not far from the calcium-hornfels repository at Botallack, that is considered to represent the fixation of the migrating silicon cations[7].

GEOCHEMISTRY

Possible Correlation between Classifications and Potassium–Argon Ages of Chondrites

ACCORDING to Kirsten *et al.*[1] and Hintenberger[2], the frequency distribution curves of the potassium-argon ages of stone meteorites show two distinct maxima. One occurs at ages close to 4·5 × 10^9 years, the other occurs around 1 × 10^9 years. However, if one classifies the chondrites into the Urey–Craig[3] *L*- and *H*-groups a relationship between classifications and gas retention ages is apparent (Fig. 1). The classification in *L*- and *H*-groups (that is, hypersthene-olivine and bronzite-olivine chondrites respectively) is based on the following chemical-mineralogical parameters: bulk iron[3], specific gravity[4], metallic nickel–iron[4,5], and Fe/Fe + Mg ratios in olivine and rhombic pyroxene[6,7]. Only well-classified chondrites have been included. Carbonaceous chondrites and enstatite chondrites have been excluded since they constitute separate groups[7]. Fig. 1 shows the frequency distribution of chondrites with well-known classification and well-determined age. The age values were taken from Anders[8] and Kirsten *et al.*[1]. The diagram shows that the substantial degassing, which leads to an apparent potassium–argon age of about 1 × 10^9 years, is, on the basis of the chondrites investigated so far, considerably more frequent for the *L*-group of chondrites than for the *H*-group. The uranium–helium ages are also plotted in the diagram, showing a similar effect. New potassium–argon age measurements[9] seem to yield some more *H*-group chondrites with low potassium–argon ages. However, recent uranium–helium measurements[10] again seem to support an age-classification relationship as indicated in Fig. 1. The purpose of this communication is to direct attention to the apparently more frequent, substantial degassing of *L*-group chondrites in comparison to *H*-group chondrites, and to emphasize the necessity for more potassium–argon gas retention age measurements of chondrites, for which the classification into *L*- and *H*-groups is well known.

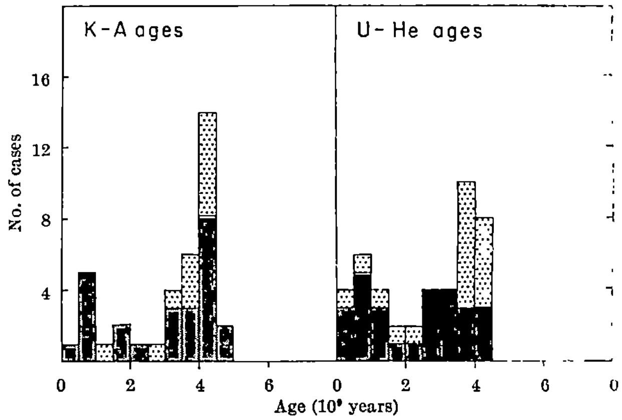

Fig. 1. Correlation between classifications and ages of chondrites. Dark shading, *L*-group chondrites; light shading, *H*-group chondrites

CRYSTALLOGRAPHY

Arsenides and Antimonides of Niobium

The phase relationships in the systems niobium–arsenic and niobium–antimony have been studied by X-ray methods. Density determinations and magnetic susceptibility measurements have been carried out.

The existence of the Nb_3Sb phase reported by Matthias *et al.*[1], Wood *et al.*[2] and Nevitt[3] has been confirmed. The NbAs phase has independently been examined by Boller and Parthé[4] and by us. The occurrence of three other previously unknown phases, the Nb_5Sb_4, $NbAs_2$ and $NbSb_2$ phases, have been established.

The lattice dimensions and observed densities are:

	a (Å)	*b* (Å)	*c* (Å)	β(°) or *c*/*a*	d_{pycn} (g cm^{-3})
NbAs	3·4517		11·680	3·3838	7·93
$NbAs_2$	9·357	3·3823	7·792	119·46	7·41
Nb_3Sb	5·2643				8·83
Nb_5Sb_4	10·314		3·556	0·3448	8·17
$NbSb_2$	10·239	3·6319	8·333	120·07	8·22

As the lattice constants are almost invariable for specimens with different initial proportions of the components no composition ranges of the phases are indicated.

The crystal structures, that is, types or space groups and parameters, are:

NbAs: Space group $I4_1$ or $I4_1md$
4 Nb and As in (*a*)
Nb: $z = 0$; As: $z = 0{\cdot}416 \pm 0{\cdot}001$

$NbAs_2$: Space group *C*2
4 Nb, As_I and As_{II} in (*c*)

	x	*y*	*z*
Nb	0·3444	½	0·3044
As_I	0·0948	0·488	0·3928
As_{II}	0·1399	0·067	0·0257

Nb_3Sb: β-*W* type
Nb_5Sb_4: Ti_5Te_4 type
$NbSb_2$: Space group *C*2
4 Nb, Sb_I and Sb_{II} in (*c*)

	x	*y*	*z*
Nb	0·343	½	0·304
Sb_I	0·096	0·5	0·393
Sb_{II}	0·142	0·0	0·027

NbAs, $NbAs_2$ and $NbSb_2$ have diamagnetic susceptibilities, whereas Nb_3Sb and Nb_5Sb_4 show weak temperature independent paramagnetism.

Details of the structures and discussion of the chemical bonding will be published elsewhere.

We thank Prof. Haakon Haraldsen for his advice.

Note added in proof. Since this communication was submitted for publication an independent confirmation of the existence of the N6As and $N6As_2$ phases has been published by Saini *et al.*[5].

Crystal and Molecular Structure of 1,3-Dihydro-1-hydroxy-3-oxo-1,2-benziodoxole

O-IODOSOBENZOIC acid (*I*) has been recognized as an atypical compound ever since it was first synthesized[1]. Askenasy and Meyer[2] suggested that this compound existed as a 5-membered heterocyclic ring. This cyclic configuration was substantiated by the infra-red studies of Bell and Morgan[3]. Further evidence favouring the heterocyclic ring structure was offered by Wolf and Hsu[4], who synthesized homologues of (*I*) with 6- and 7-membered heterocyclic rings. In view of the lack of information concerning the chemical bonding of the iodine in these heterocyclic compounds, the present X-ray investigation of (*I*) was undertaken.

(*I*) crystallizes from water as fine monoclinic needles elongated along the *b* axis. The following crystallographic data were obtained for these crystals:

$a_0 = 12{\cdot}89 \pm 0{\cdot}01$Å
$b_0 = 4{\cdot}10 \pm 0{\cdot}02$Å
$c_0 = 14{\cdot}05 \pm 0{\cdot}01$Å
$\beta = 96{\cdot}73 \pm 0{\cdot}05°$

$Z = 4$
$\rho_{obs} = 2{\cdot}38 \pm 0{\cdot}03$ g cm^{-3}
$\rho_{cal} = 2{\cdot}33 \pm 0{\cdot}01$ g cm^{-3}
Space group $P2_1/c$

Three layers of Weissenberg intensity results were obtained with copper $K\alpha$-radiation from a crystal mounted along *b*. The intensities of 520 independent reflexions were measured from these photographs, in part with a micro-densitometer and in part visually. The intensity results were converted to F^2 in the usual manner. Absorption corrections were not made because the crystal was only 0·06 mm in diameter. The structure factors were initially scaled together by means of *hk*0 and 0*kl* precession data, and the interlayer scaling was further improved during the final stages of least-squares refinement.

The co-ordinates of the 11 atoms in this structure were readily obtained from 3-dimensional Patterson and Fourier syntheses. The refinement of these parameters was carried out isotropically by least squares, minimizing the function $\Sigma w\,(|F_0| - G\,|F_c|)^2$. The *R* value (the usual discrepancy index) was 13·7 per cent after 5 cycles of refinement.

Fig. 1 is a view of (*I*) as it appears down the *b* axis. The features of major interest in this structure are:

(1) The C(1)—I, O(3)—I and O(2)—I bond distances are 2·16, 2·00 and 2·30 ± 0·05 Å respectively. The first two of these are in agreement with the sum of the covalent radii, 2·1 and 2·0 Å (ref. 5), respectively. The greater length observed for the I—O(2) bond may possibly be due to steric strain in the molecule and/or a greater amount of ionic character in this bond over the normal covalent bond.

(2) The O(2)—I—C(1) and O(3)—I—C(1) angles are 77° and 89° ± 4° respectively. These angles are similar in magnitude to those reported by Archer and Van Schalkwyk[6]

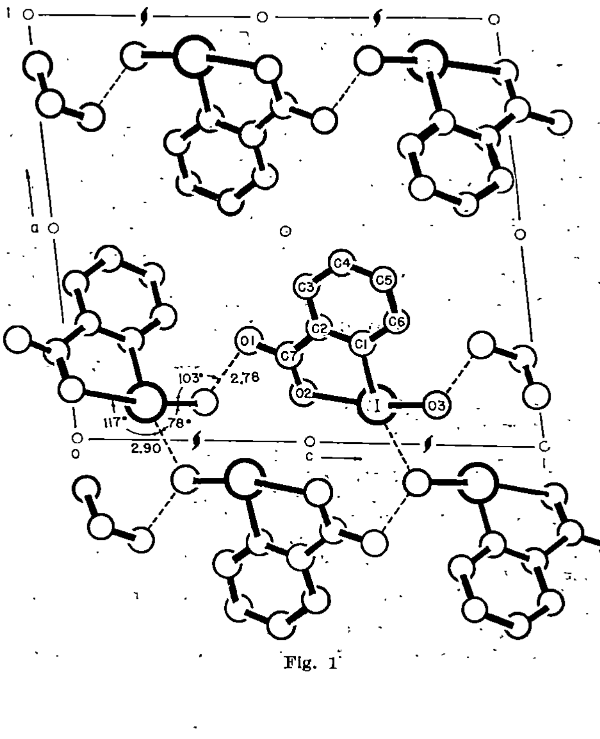

Fig. 1

for the trivalent iodine compound benzene iodo dichloride (angles of 86°). The geometry at the iodine is in accord with that found in BrF_3 (ref. 7) and ClF_3 (ref. 8).

(3) The 11 atoms in the molecule are coplanar within twice the estimated standard deviation of the individual atoms.

(4) By consideration of the angles and distances around O(3), it appears that it is hydrogen bonded to O(1) of a neighbouring molecule. The distance of this hydrogen bond was found to be 2·8 ± 0·1 Å.

(5) The contact between the iodine of one molecule and O(3) of another molecule related to the first by the screw axis is 2·90 ± 0·05 Å (Fig. 1). This distance is significantly less than the sum of the van der Waals radii of the two atoms, which is 3·6 Å. This O(3) atom is within 0·6 Å of the least squares plane of the first molecule. This type of interaction has been observed in various iodate structures[9]. Trueblood[10] has suggested that this may be another reflexion of the tendency of the iodine atom to act as a weak Lewis acid, manifested in many polyiodides and other 'complexes'.

Unit Cell and Space Group of Co(thiourea)$_4$·(NO$_3$)$_2$

A PRELIMINARY X-ray investigation of the crystal of $Co[SC(NH_2)_2]_4(NO_3)_2$ has been made, using the method of Rossenheim and Meyer for preparing the compound. It crystallized as dark blue prisms. The unit cell dimensions of the monoclinic crystal were determined from single crystal rotation and Weissenberg photographs using copper $K\alpha$-radiation.

The values found are: $a = 20{\cdot}31$ Å; $b = 16{\cdot}80$ Å; $c = 11{\cdot}68$ Å (all ± 0·03 Å); $\beta = 91{\cdot}6 \pm 0{\cdot}2°$. $V = 3{\cdot}984$ Å^3. The number of molecules per unit cell is $N = 8$; calculated value 8·17 for a density of 1·65 g/c.c.

Observed extinctions were $h+k$ odd for hkl and k odd and l odd for $h0l$ and k odd for $0k0$ reflexions, which are consistent with the two space groups, C_s^4–C_c and C_{2h}^5–$C_{2/c}$.

Statistical determinations of the centre of symmetry by Ramachandran's method showed the presence of centre of symmetry for the projection [001] as required for the group C_{2h}^6–$C_{2/c}$.

PHYSICS

Suggested Units for Conductivity

IN the hybrid system of units most frequently used for electrical conductivity σ the units are ohm^{-1} cm^{-1}. Often the atrocity mho/cm is used and neither form is particularly convenient if it is necessary to specify the units several times in a short space.

After giving due consideration to the disadvantages of introducing still another form of notation into the already overburdened literature, it is felt that the abbreviation 'roc' to stand for reciprocal ohm-centimetre is a worthwhile addition. The M.K.S. form follows, that is,

$$\sigma[\text{rom}] = 100\,\sigma[\text{roc}]$$

Rapid Non-destructive Analysis of Oxygen by Neutron Activation

IT is known that in 29·4 sec oxygen-19 is formed by neutron irradiation of natural oxygen and that it emits 0·200-MeV γ-ray. Since the activation cross-section of ^{18}O (n, γ) ^{19}O and the abundance of oxygen-18 are both low (0·21 ± 0·04 m barn[1], 0·204 per cent[1], respectively), the activation analysis using oxygen-19 is only applicable to the determination of macro-amounts of oxygen.

A sample is irradiated for 30 sec in a *JRR*-1 reactor at a neutron flux of about 3×10^{11} n/cm^2/sec, cooled for 30 sec, counted for 30 sec, again cooled for 10 sec and counted for 30 sec. The counter used is a 2-in. thick × 1·75-in. diam., well-type sodium iodide crystal attached to an *RCL*-256 channel pulse height analyser. During the counting operation the sample is placed 1 cm above the crystal. An aluminium disk of 2,150-mg/cm^2 thick is used as an absorber for β-rays from the sample.

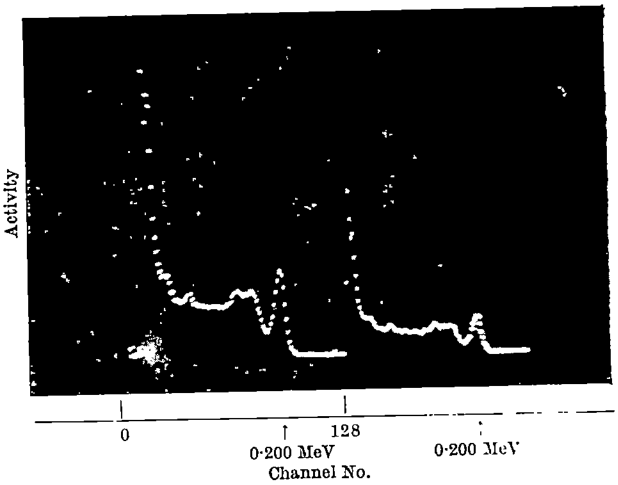

Fig. 1. γ-Ray spectrogram of oxygen-19. Sample: 5 ml. pure water

An example of successive spectra thus obtained is shown in Fig. 1. The decay curve of photopeak due to 0·200-MeV γ-ray is measured at short time-intervals and the half-life is determined as about 30 sec. From both γ-ray energy and half-life, oxygen-19 is identified.

The activation method is applied to the determination of oxygen in organic compound. Pure water is used as an oxygen standard. Oxygen is determined by comparing the peak height of 0·200-MeV γ-ray with that of standard. Some results of analyses by this method are shown in

Table 1. Results of Analyses

Sample	Oxygen content % Calculated	Neutron activation
Water	88·81	89, 87, 85
Salicylic acid	34·75	35, 36
Citric acid	60·91	61, 62
d-Mannitor	52·70	54

Table 1. The upper and lower limits of determination of oxygen are about 6 g and about 0·1 g respectively.

CHEMISTRY

Electron Spin Resonance Spectra of γ-Irradiated Alkoxides

The free radicals formed during the irradiation of alcohols frozen at −196° C have been examined extensively by electron spin resonance and, for the lower primary and secondary alcohols, they have been identified[1] as $R_1(R_2)\dot{C}OH$. A similar investigation has been made of only one of the corresponding irradiated alkoxides, namely, sodium methoxide, for which Alger, Anderson and Webb[2] observed a three-line spectrum which was similar to that from methanol, except that the proton hyperfine splitting constant (16 œ) was slightly smaller than that in methanol (18 œ). On the assumption that the alkoxides are ionic, Symons has briefly discussed this result in terms of the $\dot{C}H_2\bar{O}$ radical[3].

If other primary and secondary alkoxides behave in a similar way it should be possible to prepare other radicals of the type $R_1(R_2)\dot{C}\bar{O}$. Of particular interest among these are the aliphatic ketyl radicals, which would also be formed by electron transfer to the corresponding ketones. The electron spin resonance spectra of two highly substituted ketyl radicals (prepared by electron transfer from an alkali metal to hexamethylacetone and pentamethylacetone, respectively) in solution have been observed[4]; but so far the spectra of the smaller ketyl radicals have not been obtained.

In a preliminary investigation we have observed the electron spin resonance spectra of γ-irradiated samples of sodium and potassium methoxides, ethoxides and isopropoxides over a temperature range from −196° C to +100° C. The alkoxides were prepared by reacting the alkali metal with an excess of the A.R. grade alcohol in an atmosphere of dry nitrogen. The excess alcohol, including the alcohol of crystallization, was removed by prolonged evacuation. (The alkali metal content was estimated by titration and found to correspond closely to $R_1(R_2)CH\bar{O}M^+$.) The samples were sealed in high-purity silica tubes under dry nitrogen and irradiated at −196° C with γ-rays from cobalt-60. The electron spin resonance spectra were recorded at −196° C and at intervals as the temperature was increased to +100° C. No appreciable decay of the radicals occurred below +20° C for any of the alkoxides.

The spectra observed from irradiated potassium methoxide, ethoxide and isopropoxide at +20° C are shown in Fig. 1. Those observed from the sodium alkoxides were similar but not so well resolved. In all cases the resolution increased as the temperature was raised from −196° C. The spectra can be interpreted logically as arising from the radicals $\dot{C}H_2\bar{O}$, $CH_3\dot{C}H\bar{O}$ and $(CH_3)_2\dot{C}\bar{O}$, respectively, the last being the ketyl radical of acetone.

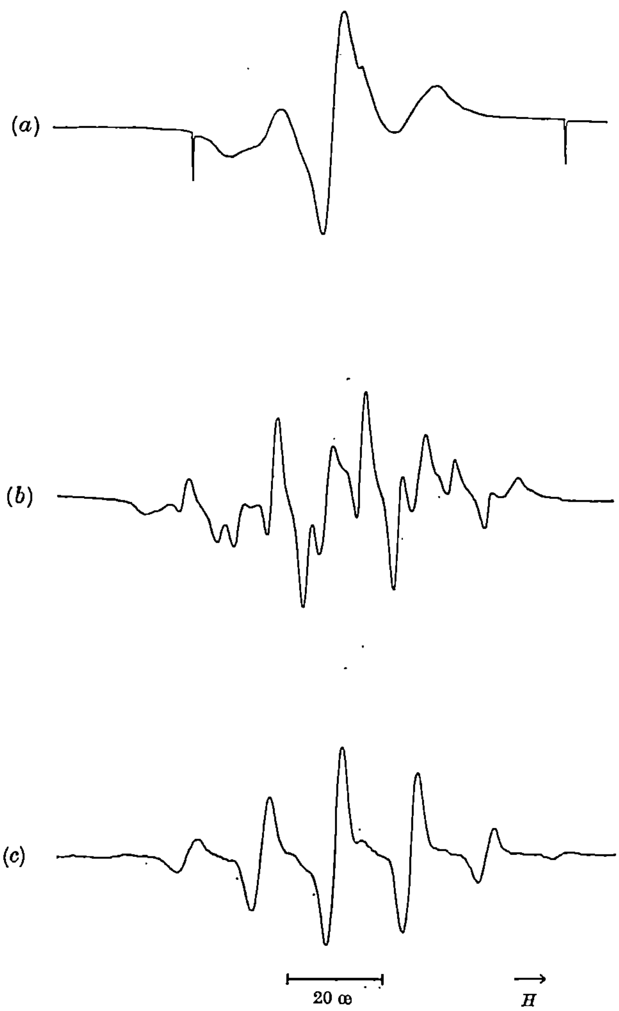

Fig. 1. First derivative spectra of γ-irradiated potassium alkoxides at +20° C: (*a*) methoxide; (*b*), ethoxide; (*c*), isopropoxide

Table 1. Hyperfine Splitting Constants for Alkoxide and Alcohol Radicals

Derivative	Hyperfine splitting constants (œ) Alkoxide* H_α	Alkoxide* H_β	Alcohol† H_α	Alcohol† H_β	Ratios $\frac{\text{Alkoxide}}{\text{Alcohol}}$ α	Ratios $\frac{\text{Alkoxide}}{\text{Alcohol}}$ β
Methyl	15	—	17·2	—	0·87	—
Ethyl	13	19·2	15·0	22·0	0·87	0·87
Isopropyl	—	16·1	—	20·0	—	0·81

* $H_\alpha \pm 1{\cdot}5$ œ; $H_\beta \pm 0{\cdot}5$œ. † Values for liquid phase, ref. 6.

The three lines observed in the spectrum of the methoxide are caused by interaction of the unpaired electron with the two α-protons. The shape of the outer lines shows that there is an anisotropic contribution to the hyperfine splitting and the overall spectrum is similar to that expected from a rotating $\dot{C}H_2$-group[5]. The spectrum of the ethoxide consists of eight asymmetric lines which can be arranged into four equally spaced pairs of lines with intensity ratios of approximately 1 : 3 : 3 : 1. This grouping can be accounted for by assuming that there is an isotropic hyperfine interaction with three equivalent β-protons and an anisotropic interaction with one α-proton. In marked contrast the seven lines in the spectrum of the isopropoxide are symmetric and well resolved. The lines are equally spaced and have relative intensities of approximately 1 : 6 : 15 : 20 : 15 : 6 : 1, showing that there is an isotropic interaction with six equivalent β-protons.

The hyperfine splitting constants based on this analysis are given in Table 1 together with those for the corresponding alcohol radicals observed in the liquid phase[6]. The isotropic β-proton splitting constants can be measured accurately, but because of the anisotropic contribution the α-proton splitting constants are less accurate. We have calculated the latter using the line shape analysis derived by Cochran, Adrian and Bowers[5]. The splitting constants for the alkoxides are consistently lower than those of the corresponding alcohol radicals (about 85 per cent), showing that the spin density on the α-carbon atom is less in the alkoxide. This reduction can be attributed to the participation of the structure $\rangle\bar{C}-\dot{O}$ in the alkoxide.

The results on the isopropoxide confirm the prediction[1] that the hyperfine splitting constant of the ketyl radical $(CH_3)_2\dot{C}\bar{O}$ should be a few œrsteds smaller than that of the isopropanol radical $(CH_3)_2\dot{C}OH$.

Determination of the Initial Formation Temperature of Nickel Ferrite Spinel

Little information is to be found in the literature[1,2] about the merits of different techniques which may be used for the detection of initial spinel formation temperatures. This communication compares a number of methods which have been used for determining the spinel formation of nickel ferrite, $NiFe_2O_4$.

A mixture of iron and nickel oxides, both of > 99·7 per cent purity, in the proportions appropriate to the stoichiometric formation of nickel ferrite, was prepared by the usual powder metallurgy techniques[3]. Magnetic susceptibility measurements, electrical resistivity measurements and X-ray diffraction measurements were carried out on samples of the mixture that had been calcined in air for 4 h at temperatures ranging from 400° to 1,260° C. The reaction was also followed by thermal gravimetric analysis and differential thermal analysis. From the results of these measurements shown in Fig. 1 and Table 1, it is apparent that the five techniques show a spread of about 100° C in the detected initial formation temperatures.

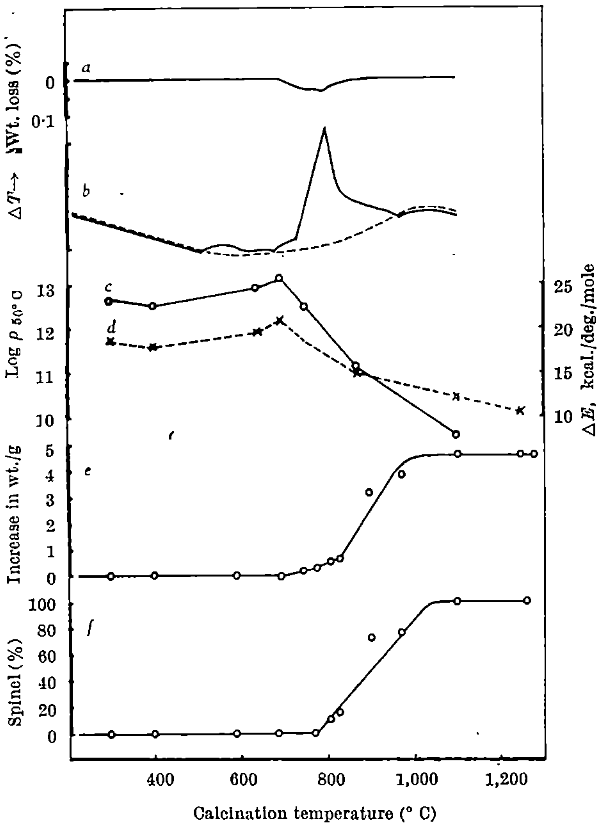

Fig. 1. Initial spinel formation temperature of nickel ferrite determined by: *a*, Thermal gravimetric analysis; *b*, differential thermal analysis (dotted line, estimated base line); *c*, electrical resistivity; *d*, activation energy (calculated from log $\rho_{50-100°\,C}$); *e*, magnetic susceptibility (Gouy method); *f*, X-ray diffractometry. Samples for *c*, *d*, *e*, *f* were calcined for 4 h in an air atmosphere

Table 1. $NiFe_2O_4$ Spinel Formation Temperatures

Method	Initial spinel formation temperature (°C)	Complete spinel formation temperature (°C)
Thermal gravimetric analysis	690	900
Differential thermal analysis	730	965
Electrical resistivity	690	—
Activation energy	690	—
Magnetic susceptibility	750	1,100
X-ray diffractometry	780	1,100

The measurement of electrical resistivity appears to be the most sensitive method; the change from the defect conductivity of NiO and Fe_2O_3 to the electron conductivity of the spinel shows clearly at 690° C. In addition to the absolute value of resistance, the activation energy of conductivity has also been calculated and plotted, indicating a similar sharp peak.

The magnetic susceptibility and X-ray diffraction techniques, while not quite so sensitive as the electrical resistivity method, enable quantitative information to be obtained about the temperature of complete ferrite formation. All three methods suffer from the disadvantage of requiring lengthy sample preparation.

Both the thermal analytical techniques—thermal gravimetric analysis and differential thermal analysis—provide a much quicker method of measurement, but the results are only of a qualitative nature. In the analysis of the formation of nickel ferrite, differential thermal analysis is much more satisfactory than thermal gravimetric analysis, but for other ferrites, where a reduction occurs in the oxide mixture (for example, MnO_2 plus Fe_2O_3), thermal gravimetric analysis can provide both qualitative and quantitative data about the spinel formation process.

This work is being continued with other transition metal spinels of the formula MFe_2O_4, where M = Cu, Co, Mg, Mn and Zn, and the complete investigation will be published shortly.

Effect of Substituents on Electrical Conductivity of Anils

This communication reports an attempt to approach the problem of electrical conductivity in organic solids from the point of view of classical organic chemistry. A series of anils derived from salicylaldehyde and various meta- and para-substituted anilines (Fig. 1) has been prepared and the electrical conductivities of compressed silver-coated polycrystalline pellets of each species have been measured. Most of these materials showed an observable dark conductivity under vacuum even at temperatures at which they were shown to be essentially non-volatile. It seems unlikely, therefore, that the conduction process could be described at these temperatures by a surface mechanism such as has been proposed by Eley *et al.*[1] for volatile organic crystals.

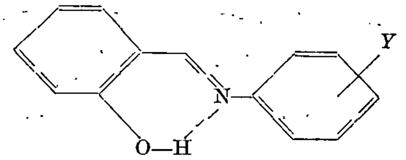

Fig. 1. Anil molecule ($Y = p$-*F*, *m*- and *p*-OCH_3, CH_3, Cl, Br, NO_2)

Materials were recrystallized three times from alcohol, dried under vacuum and finally zone refined. This last step produced no substantial change in electrical conductivity for two materials and was therefore omitted in subsequent sample preparations. In each case the relationship between conductivity and temperature could be adequately described by the equation $K = K_0 \exp(-\Delta\varepsilon/2kT)$. Ohm's law was obeyed for field strengths up to 5,000 V/cm.

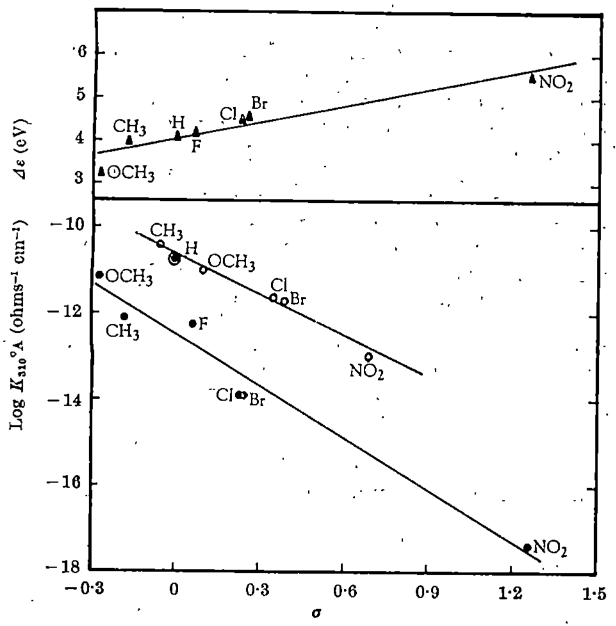

Fig. 2. Correlation of log *K* and $\Delta\varepsilon$ values and the Hammett substituent constant (σ). ▲ $\Delta\varepsilon$ versus σ for *para*-substituents; ○ log *K* versus σ for *meta*-substituents; ● log *K* versus σ for *para*-substituents

A correlation exists (Fig. 2) between log *K* and the Hammett[2] substituent constant (σ) for both the *meta*- and *para*-series of substituents, and between $\Delta\varepsilon$ and σ for the *para*-series. Thus anils containing substituents (Y) which transfer charge to the aniline ring were found to be the best conductors and in the case of *para*-substituents to have the lowest $\Delta\varepsilon$ values. This is reminiscent of the correlation found by Pullman and Pullman[3] between basic strength and ionization potential of the nitrogen lone-pair electrons for a number of biologically important compounds.

Comparing the two series, anomalies are at once apparent, for the unsubstituted salicylidene-aniline complex is out of place in the log *K* versus σ correlation for *para*-substituents, but in place in the *meta*-series. The fact that log *K* versus σ correlations exist for the two series separately but not for the overall series of substituents may indicate that closer-molecular packing occurs in crystals of the *meta*-series with consequent increase in molecular orbital overlap, carrier mobility and hence conductivity. Differences in packing arrangements among crystalline salicylidene anilines have been reported by Cohen and Schmidt[4].

Chelation of these anils with divalent metal ions produced a manifold drop in conductivity, indicating presumably that the electrons involved in the *N*-metal bond are no longer capable of contributing to the conduction process. Further evidence for this exists in that the conductivities of the metal chelates were in the order nickel > copper, whereas their stabilities, which indicate the strengths of the nitrogen-metal bonds, are in the reverse order.

Photolysis of Nitrosyl Chloride by Ultra-violet Radiation

The photolysis of nitrosyl chloride was investigated first by Kiss[1], and later by Bowen and Sharp[2], who found that the quantum yield was 0·5 in both the spectral regions 4380–5000 Å, and 4480–5200 Å. Kistiakowsky[3] investigated the reaction more fully, using essentially monochromatic light derived either from a mercury arc, or from a tungsten filament lamp, both used in conjunction with filters. He concluded that the mean quantum yield for the decomposition over a range of wave-lengths from 6350 Å to 3650 Å was 2·1. At 3650 Å the quantum yield was 2·7, although Kistiakowsky believed that this value was incorrect because of the partial absorption of the ultra-violet radiation by the 'Pyrex' windows of the reaction cell. He suggests that the results of Bowen and Sharp disagree with his own either because they used non-monochromatic light, or because they neglected the dark reaction.

Basco and Norrish[4,5] have recently examined the flash photolysis of nitrosyl chloride under isothermal conditions. They observe that molecules of nitric oxide with up to 11 quanta of vibrational excitation are formed, which they suggest are produced in the primary process:

$$NOCl + h\nu = NO^* + Cl \qquad (1)$$

These vibrationally excited molecules of nitric oxide possess sufficient energy to allow of the reaction:

$$NO^* + NOCl \doteq 2NO + Cl \qquad (2)$$

Since the chlorine atoms formed in reactions (1) and (2) will both react with nitrosyl chloride:

$$Cl + NOCl = NO + Cl_2 \qquad (3)$$

it is possible for the quantum yield to reach a maximum value of four, rather than the limiting value of two possible when only reactions (1) and (3) take place. In the light of these considerations, Kistiakowsky's high value of 2·7 for the quantum yield at 3650 Å assumes a new significance. At that wave-length, the excess energy available from reaction (1) is only marginally sufficient to cause dissociation of the second molecule of nitrosyl chloride.

It is of considerable interest to find out whether vibrational energy possessed by a molecule can be used to provide the energy required for that molecule to enter into otherwise endothermic reactions. In order to determine whether reaction (2) does, in fact, take place, the quantum yield must be measured at shorter wave-lengths than those used by Kistiakowsky. In the present work, the quantum yield for the photochemical decomposition of nitrosyl chloride has been determined at a wave-length of 2537 Å, where there is more than 70 kcal/mole of excess energy available in reaction (1).

Mercury resonance radiation was obtained from a low-pressure lamp, which consisted of a flat quartz spiral, about 7 cm diameter, with water-cooled electrodes. It was filled with a mixture of 90 per cent neon and 10 per cent argon, to a total pressure of 1 cm mercury, and contained also a small drop of mercury. The radiation from this lamp was passed through a filter system to remove the small amount of visible and near ultraviolet radiation emitted by the lamp, and was then focused by two quartz lenses through the thermostated reaction cell on to a 1*P*28 photomultiplier tube. The quantum input to the reaction cell was determined using potassium ferrioxalate actinometer solutions according to the method of Hatchard and Parker[6]. The reaction was followed manometrically with a 'Pyrex' modified spoon gauge[7], with a sensitivity magnification of 45 : 1 compared with a mercury manometer. The resonance lamp and the optical system are more fully described elsewhere[8]. Mercury vapour was rigorously excluded from the reaction system to avoid the possibility of photosensitization.

Nitrosyl chloride was prepared by allowing a mixture of 0·2 atm. chlorine and 0·8 atm. nitric oxide to stand together in a darkened bulb for three days. The mixture was condensed in a liquid nitrogen trap, and the temperature then raised to −80° C, when the excess nitric oxide was pumped off. The crude nitrosyl chloride was redistilled under reduced pressure, and stored as a solid at liquid nitrogen temperature.

The quantum yields obtained for a number of different pressures of nitrosyl chloride, and for mixtures of nitrosyl chloride with inert gases, are shown in Table 1.

Table 1. QUANTUM YIELDS OF THE PHOTOLYSIS OF NITROSYL CHLORIDE

Run	Mixture	$T = 25°$ C quantum yield ($\lambda = 2537$ Å)
1	6 cm NOCl	1·95
2	6 cm NOCl	2·00
3	6 cm NOCl	1·95
4	6 cm NOCl	1·96
5	12 cm NOCl	1·92
6	12 cm NOCl	1·83
7	2 cm NOCl	2·34
8	1 cm NOCl	1·88
9	6 cm NOCl + 76 cm N_2	1·92
10	6 cm NOCl + 40 cm CO_2	1·88
11	6 cm NOCl + 76 cm Ar	1·90

It is seen that the quantum yield of the photolysis is approximately independent of the pressure of the nitrosyl chloride and of the presence of gases such as nitrogen, argon or carbon dioxide. The mean value for the quantum yield is 1·96 ± 0·08, so it may be concluded that reaction (2) proceeds to a negligible extent. The insensitivity of the quantum yield to the presence of carbon dioxide is further evidence that vibrationally excited nitric oxide does not enter into the reaction, since carbon dioxide might be expected to be an efficient quenching agent for vibrational excitation.

The results of Kistiakowsky may now, therefore, be extended into the ultra-violet region, the quantum yield remaining close to two.

I thank Prof. R. G. W. Norrish for providing the facilities of his laboratories.

Structure of the β-Lactoglobulin Tetramer

DETAILED investigations of the association behaviour of the genetic variants of β-lactoglobulin have shown that the *A* variant aggregates strongly and reversibly to a tetramer[1,2] of 144,000 molecular weight in the cold between *p*H 3·7 and 5·2. The thermodynamics of this association have established the tetramer structure to be cyclic, involving the closing of four bonds[1,2], and its hydrodynamic properties[2,3] show it to be compact. A small-angle X-ray scattering examination of this association[4] has led to the conclusion that, of the various general types of possible tetramer structures, a cubic array of eight spheres was the most probable. This conclusion was based on comparison of the measured radius of gyration of the tetramer (34·4 Å) with values calculated for various models formed of four of the monomeric units deduced by Green and Aschaffenburg[5] from X-ray diffraction examination. These monomeric units have been shown to persist in solution[4]. The monomer unit consists of a combination of two identical spheres (of molecular weight 18,000) 17·9 Å in radius, impinging by 2·3 Å along their centre-to-centre axis; these two spheres are, furthermore, related by a dyad axis of symmetry through the plane of contact formed between them. Recently, we have carried out a detailed examination of compact models in the light of known structural requirements, the results of which we wish to report in this communication. The basic requirements are that all four monomer molecules must be identical with each other[2], the monomer structure must be maintained intact in the tetramer[4], and the structure must fit all known experimental information and be symmetrical in nature[6].

First, let us examine the previously proposed structure[4], that is, the cubic array of eight spheres, shown in Fig. 1*A*. In this model the four 36,000 molecular weight monomer units are aligned with polar axes vertical, and with the surfaces of contact between the spherical sub-units lying in one plane (Fig. 1*B*); the four dyad axes of symmetry are in the same plane along the diagonals of the cross-section square. Careful examination of this structure reveals that the closing of four bonds between the monomers in such manner that each spherical sub-unit is linked to one belonging to another monomer molecule, without at the same time violating the dyad axes of symmetry, requires the presence of two pairs of monomers in which the tetramerization sites are disposed as shown in Fig. 1*C*, that is, each type is the mirror image of the other[7]. Since this structure violates the requirement of identity between the four monomers, it must be ruled out. This requirement can be satisfied, however, by the second cubic structure shown in Fig. 1*D*. In this, one pair of monomers is rotated 90° with respect to the other, the surfaces of sub-unit contact (shown shaded) now lying in pairs in two mutually perpendicular planes; the dyad

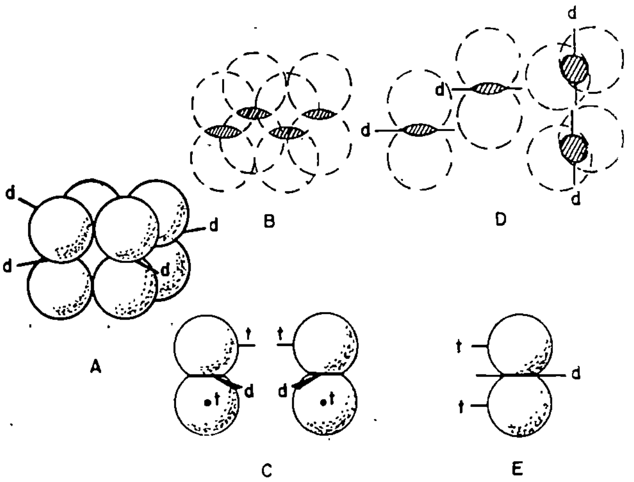

Fig. 1. Cubic models of lactoglobulin tetramer. (*A*) All four double spheres aligned vertically; (*B*) same, showing planes of sub-unit contact; (*C*) monomer structures required to close tetramer bonds in model (*A*); (*D*) monomers aligned in two pairs, one vertical, the other horizontal; (*E*) tetramer bond location on monomers in structure (*D*). In this and Fig. 2 the dyad axes of symmetry are designated by *d*, the tetramer bonds by *t*

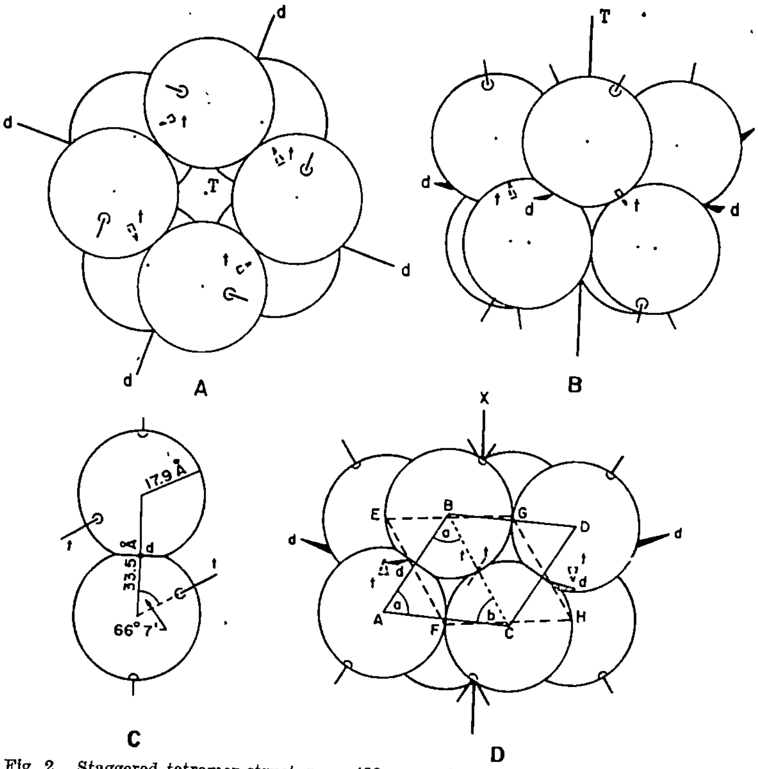

Fig. 2. Staggered tetramer structures. 422 symmetry: (*A*) top view; (*B*) side view. *T* indicates the tetrad axis of symmetry; (*C*) monomer structure required by structure (*A*, *B*); (*D*) 222 symmetry: *X* indicates overall dyad axis of symmetry; distances *AB*, *CD*, *EF*, *GH* = 33·5 Å; *AE*, *BC*, *FG*, *DH* (along tetramer bonds) = 35·8 Å. Angles *a* = 62° 8′; *b* = 55° 44′

axes are located in pairs, one pair remaining in the horizontal intersphere plane, the other pair on a vertical line going through the sub-unit contact planes of the monomers the polar axes of which are in the horizontal position. In this arrangement, the two tetramer bonds of a monomer must be located in one plane and directed at a right angle to the polar axis of the two-sphere structure, as shown in Fig. 1*E*. While this structure satisfies the requirements of structural identity, it lacks overall symmetry and, as such, is probably less likely. Furthermore, this model requires a 90° rotation of each sub-unit along the tetramer bond with respect to its tetramer partner: complementarity, if necessary for this type of bond, would not be compatible with the dyad axis of symmetry.

A symmetrical tetramer structure, satisfying all the requirements, can be constructed by arranging the monomers in an inclined array, which results in the decahedron shown in two views in Fig. 2*A* and *B*. Here, the four dyad axes of symmetry, *d*, and the four points of tetramer contact, *t*, are all in one single plane perpendicular to a central tetramer axis, *T*. The dyad axes are normal to this central axis. The tetramer bonds lie on the corners of a square; the two bonds on each monomer are located symmetrically on the sub-units and their projection on the plane of sub-unit contact forms a 90° angle. In the tetramer, they are inclined at an angle of 35° with respect to the vertical, the bond from the upper sphere pointing downward, that from the lower sphere upward. Thus, the upper sphere of each monomer forms a tetramer bond with the lower sphere of another monomer. Since the monomeric units are inclined at an angle of 31° with respect to the vertical, the inclination of the tetramer bonds with respect to the polar axis of the monomer is 66°. When viewed along the tetramer axis, *T* (Fig. 2*A*), the centre of each sphere in the upper layer is located asymmetrically between those of the two lower ones with which it is in contact. This arises because of the difference in centre to centre distances: 33·5 Å within the monomer, 35·8 Å along the tetramer bond.

The locations of the tetramer bonds and dyad axis in the monomer are shown in Fig. 2*C*. The three-sphere relationship in the tetramer structure of Fig. 2*A*–*B* is identical to the one shown by triangle *ABC* in Fig. 2*D* (in which another possible structure, to be discussed as follows, is depicted); angles *a* are 62° 8′, angle *b* is 55° 44′. The structure of Fig. 2*A* and *B* is characterized by a principal four-fold axis of symmetry, *T*, which coincides with the vertical axis through the centre of the structure. Fig. 2*A*–*B*, then, has 422 symmetry. Furthermore, in this model, intermolecular contacts are limited to the tetramer bond sites plus two further points of contact with neighbouring spheres. A cavity is present along the vertical tetrad axis, with an average diameter of about 18 Å; this permits access of water molecules, leaving some interior molecular surface in contact with solvent. Since it is quite probable that the surface of the protein molecule contains a high density of polar residues[8], this structure entails the burial of a minimal amount of polar side-chains in the low dielectric constant interior of the tetramer and, thus, the expenditure of least energy for this purpose[8–11].

One more structure which should be considered is shown in Fig. 2*D*. This is derived from the previous one by rotating alternate monomers through 45° in opposite directions about the tetramer bonds. In this structure the monomers are located in two lozenge-shaped arrays of four spheres each, the short diagonals of the two lozenges being in parallel planes and inclined in opposite directions. The lozenges are slightly folded inward along the short diagonal. The four dyad axes of symmetry, *d*, remain, as before, in one plane which also passes through the points of tetramer contact. The tetramer bonds, *t*, are present here in two conformations, two bonds lying along the short diagonals and two perpendicular. The presence of a principal dyad axis of symmetry, *X*, gives this structure 222 symmetry. In this structure, however, there is less symmetry than in the previous one. The tetramer bonds exist in two different conformations making structural complementarity across these bonds impossible. Also, the spherical sub-units are in two groups, differing by their environment: four, units *B*, *C*, *F* and *G*, make contact with five other spheres each; the others, *A*, *D*, *E* and *H*, make contact with four other sub-units each. Thus, the amount of monomer molecular surface which must be buried in the hydrophobic interior of the tetramer is considerably larger than in structure 2*A*. As a result, it is considered that structure 2*D* is less likely to occur, even though it is an isomer of the previous one formed only by rotation about the tetramer bonds. It is of interest to note that the model of Fig. 2*D* is one of the extremes allowed by the rotation of Fig. 2*A* about the tetramer bonds (assuming no complementarity); the other extreme (a mirror image) is produced by 90° rotation of 2*D* in the opposite direction.

The radii of gyration of the three structures have been calculated using the monomer molecular dimensions of Green and Aschaffenburg[5], with the results shown in Table 1. As can be seen, all three fit the small-angle X-ray scattering data[4] equally well.

On the basis of the foregoing analysis, and in particular the element of symmetry present in each model considered and the energy required to bring polar residues into the low dielectric medium in the interior of the tetramer, the structure of Fig. 2*A*–*B* (422 symmetry) is regarded as the favoured one. (The identical tetramer structure has been deduced independently by Dr. D. W. Green

Table 1. RADII (R) OF GYRATION OF TETRAMER MODELS

Model	R (Å)
Cube	33·4
422	33·4
222	33·1
Experimental	34·4 ± 4

(private communication).) Structural fluctuations between it and the two 222 structures (Fig. 2*D* and its mirror image) are not excluded, although unlikely, since they would destroy complementarity about the tetramer bonds and would involve the expenditure of extra energy in the burial of additional polar groups.

[7] The cubic structure (Fig. 1*B*) could be satisfied also if each monomer sub-unit formed bonds with two sub-units of other monomers on tetramerization. This would require the closing of eight bonds on tetramerization and is thus rather unlikely. In this case, the symmetry requirements would be satisfied only if the eight bonds were of a heterologous, rather than homologous, nature.

BIOCHEMISTRY

Properties of the Penicillin Deacylase Enzyme of *Escherichia coli*

THE microbial enzyme which hydrolyses the side-chain from a penicillin to give 6-aminopenicillanic acid (6-APA) and carboxylic acid, or which catalyses the synthesis of penicillin from 6-APA and a carboxylic acid or its derivative, has been termed penicillin amidase[1-6], penicillin acylase[7], benzylpenicillin acylase[8], penicillin splitting and synthesizing enzyme[9,10] or acyl transferase[11]. Investigations of the relative ease with which an enzyme from various sources will hydrolyse a series of penicillins has revealed the existence of at least two types of enzyme[9], one hydrolysing phenoxymethylpenicillin much more readily than benzylpenicillin and the other hydrolysing benzylpenicillin much more readily than phenoxymethylpenicillin. Experiments on the hydrolysis of a series of penicillins with the *Nocardia* and *Proteus* enzymes[8] have shown that the enzyme of these organisms has preference for a particular side-chain, namely, the phenylacetyl side-chain, and that all deviations from this structure cause reduction in enzyme activity. These reports indicate that substrate specificity is governed by the nature of the side-chain of the penicillin. Very little work has been done on the effect of structural modification of the acylated group on enzyme activity, but Huang, Seto and Shull[8] do report that the use of the amide or ester of benzylpenicillin and phenoxymethylpenicillin or replacement of 6-APA by 7-aminocephalosporanic acid in various penicillins has only a minor effect on enzyme activity.

The purpose of the present communication is to report that the penicillin acylase enzyme produced by a strain of *Escherichia coli* (B.R.L. 1040) is able to remove the phenylacetyl group from a wide range of phenylacetylated compounds and is thus not specific for the deacylation of penicillins and their derivatives. or for the cephalosporins.

Table 1. RATES OF HYDROLYSIS OF VARIOUS PHENYLACETYL DERIVATIVES BY THE ACYLASE ENZYME OF *E. coli* B.R.L. 1040

	Initial rate of hydrolysis* (µmoles/ml./min)
Phenylacetylglycine	0·12
Phenylacetyl D-α-aminophenylacetic acid	0·00
Phenylacetyl L-α-aminophenylacetic acid	0·092
Phenylacetamide	0·072
Benzylpenicillin	0·066
Phenylacetyl ε-aminocaproic acid	0·056
Phenylacetyl DL-leucine	0·048
Benzylpenicillin penicilloic acid	0·0144

* The reaction mixtures consisted of M/100 substrate and *E. coli* B.R.L. 1040 cells collected and resuspended at one-quarter the density at which they occurred in the growth medium. The *p*H was kept at 8·0 by automatic addition of M/50 sodium hydroxide. The reaction mixtures were stirred at 37° C.

The rate of hydrolysis for all compounds except benzylpenicillin was determined by assaying the liberated amino-acid or ammonia by the ninhydrin method using the appropriate standard curves. The rate for benzylpenicillin was determined by titrating the released phenylacetic acid with M/50 caustic soda solution. Similar results were obtained by assaying the released 6-APA using the biological assay after conversion to benzylpenicillin with phenylacetyl chloride.

The rates of hydrolysis of various compounds containing the phenylacetyl group are shown in Table 1. The rate of hydrolysis is markedly affected by the structure of the acylated compound and it will be seen that benzylpenicillin is not the best substrate. Substrate specificity experiments using *E. coli* B.R.L. 1040 have shown that there is a very close relationship between the structures of the acyl groups preferred for hydrolysis or synthesis of penicillins and those preferred for hydrolysis or synthesis of non-penicillins. From this it is inferred that the same enzyme is involved in both penicillin and non-penicillin reactions. This is supported by the fact that examination of the distribution of benzylpenicillin deacylase and phenylacetylglycine deacylase activities within a group of *E. coli* strains has shown that the two activities always occur together and in the same proportions.

In keeping with other amino-acid acylase enzymes, for example, that of pig kidney[12], the *E. coli* B.R.L. 1040 enzyme is specific for the hydrolysis of acylated L-α-amino-acids (Table 1). Phenylacetyl-L-α-aminophenylacetic acid was completely hydrolysed while the acylated D-form was unattacked. The phenylacetyl derivatives of several DL-amino-acids were hydrolysed only to the extent of 50 per cent, but phenylacetylglycine was completely hydrolysed. Benzylpenicillin, containing the acylated L-amino group, was also completely hydrolysed.

Reaction of the *E. coli* B.R.L. 1040 enzyme with a series of penicillins has shown that benzylpenicillin and substituted benzylpenicillins were the best substrates, and tests on a series of carboxylic acids for enzymatic coupling with 6-APA showed that phenylacetic acid and substituted phenylacetic acids were the best substrates. When salts of various carboxylic acids were included in media used to cultivate the *E. coli.* B.R.L. 1040 only phenylacetic acid and structurally similar compounds were found to have the good enzyme-inducing action observed by Kaufmann and Bauer[13], phenylacetic acid being the best.

The foregoing results indicate that *E. coli* B.R.L. 1040 produces an acylase enzyme which has specificity for the phenylacetyl group but which is not specific for penicillins. It is suggested that for the convenience of distinguishing this enzyme from other penicillin hydrolysing enzymes it be called a phenylacetylase.

Experiments with *Achromobacter* sp. B.R.L. 1755 (N.C.I.B. 9424) have shown that this organism produced an enzyme which hydrolyses phenoxymethylpenicillin more readily than benzylpenicillin, and the same enzyme preparation hydrolysed phenoxyacetylglycine more readily than phenylacetylglycine. Inasmuch as phenoxymethylpenicillin is hydrolysed more readily than benzylpenicillin, this enzyme is similar to those produced by moulds and some Actinomycetes[4,6,9].

The hydrolysis of various *N*-phenylacetylated compounds, including benzylpenicillin by *E. coli*, suggests that penicillin amidase is an acylase which does not differ fundamentally from other acylase enzymes and is able to hydrolyse benzylpenicillin because of its specificity for the phenylacetyl group. Liberation of 6-APA by deacylation of phenoxymethylpenicillin using preparations of animal tissue has already been reported[14]. Since then we have found that pig kidney acylase I (British Drug Houses, Ltd.), which will hydrolyse phenoxyacetylglycine, octoylglycine and hexoylglycine but not phenylacetylglycine, will hydrolyse the corresponding penicillins, phenoxymethylpenicillin, heptylpenicillin and pentylpenicillin, but not benzylpenicillin. It seems probable that the liberation of 6-APA by enzymatic splitting of penicillins by preparations from various micro-organisms[1–11], animals[14] and plants[15] is due to acylase enzymes which are specific for the acyl group present in the penicillin which is cleaved.

I thank Dr. G. N. Rolinson for his advice.

Variety of Substrates for a Bacterial Benzyl Penicillin-splitting Enzyme

PREVIOUS work on a cell-bound bacterial enzyme which catalyses a reversible enzymatic cleavage of benzyl penicillin to 6-aminopenicillanic acid (6-APA) and phenylacetic acid had shown that this enzyme represents an acyl transferase which, under suitable conditions, is able to synthesize penicillins by transferring acyl- and α-aminoacyl residues from acylamino acids, acyl amides, acylated hydroxycarboxylic acids, mercaptocarboxylic acids, alcohols, phenols and thiophenols to the amino group of 6-APA (refs. 1–3). Free amino-acids, ammonia, hydroxycarboxylic acids, mercaptocarboxylic acids, alcohols phenol and thiophenol, liberated in the course of those reactions, may be considered to be hydrolysis products of the acyl compounds used.

Table 1. HYDROLYSIS OF VARIOUS ACYL-COMPOUNDS BY THE PENICILLIN-SPLITTING ENZYME AT NEUTRAL REACTION

(1) Phenylacetyl L-glutamic acid $\xrightarrow{+H_2O}$ glutamic acid + phenylacetic acid
(2) DL-α-Aminophenylacetyl glycine $\xrightarrow{+H_2O}$ α-aminophenylacetic acid + glycine
(3) DL-α-Phenoxypropionyl amide $\xrightarrow{+H_2O}$ α-phenoxypropionic acid + ammonia
(4) D-α-Aminophenylacetyl methyl ester $\xrightarrow{+H_2O}$ α-aminophenylacetic acid + methyl alcohol
(5) Phenoxyacetyl glycollic acid $\xrightarrow{+H_2O}$ phenoxyacetic acid + glycollic acid
(6) *p*-Methoxy-phenoxyacetyl thioglycollic acid $\xrightarrow{+H_2O}$ *p*-methoxy-phenoxyacetic acid + thioglycollic acid

By means of some representative reactions listed in Table 1 we wish to demonstrate that a hydrolytic cleavage of acyl- and α-aminoacyl compounds as mentioned above is not dependent on the presence of 6-APA.

On the basis of these findings it is not the penicillin nucleus which seems to be important for the substrate specificity of the enzyme, but rather the acyl residue, which may be linked to different compounds. Considering the impressive variety of enzymatic reactions including those not involving penicillins, the synonymous names 'penicillin amidase' and 'penicillin acylase' proposed for this enzyme by several authors and discussed separately by Claridge *et al.*[4] and Huang *et al.*[5] are not satisfactory.

This communication forms part of a paper presented at the second International Fermentation Symposium (London, April 1964) under the title "A Bacterial Enzyme Cleaving Benzyl Penicillin".

Influence of Extraneous Ribonucleic Acid on the Differentiation of Hæmatopoietic Tissue in Chick Embryos

EXPERIMENTAL results are given here which seem to confirm the work of several investigators[1–4] concerning the ability of phenol-extracted RNA to stimulate protein synthesis in embryonic cells.

It has, indeed, been found possible to increase somewhat the amount of hæmoglobin synthesized by the isolated vascular area of the chicken embryo by the addition of phenol-extracted chicken reticulocyte RNA, rabbit reticulocyte RNA or total 3·5-day chick embryo RNA. Moreover, isolated fragments of the extra-embryonic region of the blastodisk have also been found to increase their potential for hæmoglobin synthesis in the presence of chick embryo RNA added to their culture medium.

RNA extracted by a modification of the method described by Fraenkel-Conrat[5] was suspended in chick Ringer and added to a yolk agar medium of the type recommended by Britt and Hermann[6]. Chick embryo blastodisks were explanted, washed in Ringer and transferred to the experimental medium after removal of the embryo at stages between 6 and 11 (Hamilton–Hamburger classification) such that the explanted tissue cultivated consisted mainly of presumptive hæmatopoietic tissue, particularly favourable for examining variations in net hæmoglobin synthesis over a limited experimental period.

After culture for 24 h, the explants were homogenized separately and determinations of hæmoglobin, total RNA and residual proteins were carried out by the methods of O'Brien[7], Ogur and Rosen[8] and Lowry[9], respectively.

It has thus been possible to record, in certain experimental series, an increase in the net quantity of hæmoglobin synthesized over a 24-h period by the treated explants, cultivated on an agar yolk medium containing additional RNA. Similar effects were recorded with chicken reticulocyte RNA, rabbit reticulocyte RNA or chick 3·5-day embryo RNA. A difference, varying from 4 to 39 per cent was recorded between treated and control embryos (Table 1). It has not been found possible to detect a linear relationship between increase in concentration of added RNA and the increase in hæmoglobin synthesis. In fact, a concentration of 2 mg/ml., which

was the highest concentration used, was found to be inhibitory in this system.

Normal variations in net synthesis in control explants may mask to a certain extent the differences between treated and control embryos, but even if this were so, the degree of stimulation of hæmoglobin synthesis is in no way spectacular. The fact that anabolism in the embryonic cell is extremely rapid may explain the limited extent to which external RNA, entering the cell, may find vacant sites at which to interfere with normal metabolism. Added RNA may also be partly degraded by intracellular RNase.

The effect of adding ribonucleic acid to the external medium may be greater in conditions creating a certain deficit in potential metabolism. It has, for example, been shown by Settle[10] that explants of the anterior region of the chick blastodisk at the primitive streak stage only produce hæmoglobin in 15 per cent of cases when grown on a rich albumen yolk agar medium. By adding 50 μg/ml. of chick embryo RNA to the medium, it was found possible to augment the number of such explants producing hæmoglobin from 18 per cent (controls) to 73 per cent in treated embryos.

Embryonic explants cultivated on purely mineral medium[11] did not respond to the presence of additional RNA; a rich agar medium containing yolk and albumen was required to obtain positive results. This may mean that ribonucleic acid molecules may only penetrate the cell in conditions favouring pinocytosis.

Some experimental results were negative, even in the conditions described, a result which seemed most easily explained by the degradation of ribonucleic acid under storage conditions or by intracellular RNase: the altered molecule may be inactive or even inhibitory.

The experiments described here used, in each case, a type of RNA the origin of which presupposed the possibility of its being used by the embryonic cell, as such, without modifying the normal metabolism of the cell. The question remains to be answered whether the embryonic cell responds more readily to RNA of homologous or heterologous origin. The relative efficiency of different types of RNA (transfer, ribosomal or messenger RNA) also needs to be established. It may be supposed that the RNA used in these experiments, extracted at room temperature, consisted mainly of cytoplasmic RNA, since further extractions with phenol at 45° and 65° C provided two further fractions differing from the first in their sedimentation characteristics, specific radioactivity after labelling with phosphorus-32, and base composition. When the extraction at 65° C is performed in the presence of sodium dodecyl sulphate, the resulting extract from chicken reticulocytes contains about 10 per cent DNA. The biological activity of the fractions extracted with hot phenol will shortly be tested.

In conclusion, it may be said that while these experimental results appear to confirm the role of ribonucleic acids in specific protein synthesis, they neither prove nor disprove the possibility of obtaining a specific response from embryonic cells by such externally supplied RNA.

Inhibition by a Carcinogenic Hydrocarbon of Incorporation of Tritiated Cytidine into Mouse Epidermal Cells

EARLY effects of carcinogenic hydrocarbons on the cell cycle and on deoxyribonucleic acid (DNA) synthesis have been noted by several authors. McCarter and Quastler[1,2] found that 7,12-dimethylbenz[α]anthracene (DMBA) decreases the rate of incorporation of ^{3}H-thymidine into DNA and prolongs the DNA synthetic phase of the generation cycle of mouse epidermal cells. Evensen[3] found that 3-methylcholanthrene alters the proportion of epidermal cells labelled with ^{3}H-thymidine in the hairless mouse. Jensen *et al.*[4] reported a reduction in uptake of ^{3}H-thymidine in various tissues of the mouse following the administration of DMBA, including some tissues in which tumours do not usually arise after treatment with this agent. Elgjo[5] reported that 3-methylcholanthrene changes the mitotic phase of the cell cycle over an eleven-week period. We now report an early effect of DMBA on the synthesis of ribonucleic acid (RNA) in mouse skin.

The mice used in these experiments were derived from the *CFW* strain obtained from Carworth Farms, New City, and have been maintained in this laboratory by brother–sister mating for 16 generations.

The back of each mouse was shaved and 0·15 ml. of 0·05 per cent DMBA in acetone was applied to an area of 2 cm^2 (ref. 6). After varying lengths of time the mice were killed. The full thickness of treated skin and a piece of adjacent untreated skin were excised, cut into pieces 2–3 mm^2 and incubated at 37° C in a shaking water bath for varying lengths of time in Tyrode's medium containing ^{3}H-cytidine, specific activity 1·5 c./mM at a concentration of 10 μc./ml. (Schwarz Bioresearch, Inc., Mount Vernon, New York).

Pieces of skin incubated in Warburg vessels respired at a constant rate up to at least 6 h. This respiration was penicillin-resistant and totally inhibited by boiling for 10 min. The rate of respiration was not altered to a detectable degree by DMBA treatment or the presence of the radioisotope in the incubating medium. The incubation procedure was used because doses of ^{3}H-cytidine up to 500 μc. per mouse given by intraperitoneal, intracardiac or subcutaneous injection failed to produce any labelling in the skin when autoradiographs were stored for 2 months.

The pieces of skin were removed from the incubation medium at times from zero to 11 h, washed in water and fixed in formol saline for 5–7 days. Sections having a thickness of 5–7μ were cut and autoradiographs were prepared using Kodak '*AR* 10' stripping film. The slides were examined using phase contrast.

The epidermis bordering on a scissor cut, damaged by crushing, contained no grains and served for an assessment of the background count. Within a few μ of the cut edge the grain count over epidermal cells increased sharply, remained at a constant level for 100–200μ, then fell off again fairly quickly. This border of 100–200μ was the area counted. The average grain count was determined for cells sectioned through the nucleus.

Extraction of RNA with perchloric acid[7] removed approximately 90 per cent of the label from the sections. The DNA was not appreciably labelled by incubating pieces of skin in Tyrode's medium containing ^{3}H-thymidine since the mice used were in the resting phase of the hair growth cycle. With ^{3}H-cytidine the pattern of labelling was nuclear and nucleolar at early times, then later spread to include the cytoplasm. This pattern of labelling has been reported for RNA precursors by a number of authors[8,9].

Fig. 1 shows the progress with time of labelling in epidermal cells in Tyrode's medium containing ^{3}H-cytidine. Under the continuously labelled conditions, the control area took up more ^{3}H-cytidine than was taken up by the treated area. When the skin had been transferred to non-radioactive cytidine at 1 h, the percentage reduction in grain count in DMBA-treated skin compared with the control was similar to that obtained under the continuous labelling condition. The results also indicated that there is no significant cytidine pool in epidermal cells[10].

Table 1 shows the effect of DMBA on the reduction in grain count at the indicated days after DMBA application. The 'unwashed' heading refers to experiments in which DMBA was left on, and the 'washed at 1 h' heading refers to experiments in which the DMBA remaining on the surface was removed by diethyl ether at 1 h[6]. Each test was compared with its particular control. The results were expressed as a percentage reduction in grain count so that decreases at lesser and greater degrees of labelling would be additive without weighting the results in favour of the higher absolute decreases found at longer incubation times.

It can be seen that there was a decrease ($P < 0·001$) in grain count with DMBA treatment. Although the 'washed' experiment showed a smaller decrease, it was still highly significant ($P < 0·001$).

Table 1. Effect of DMBA on incorporation of ^{3}H-cytidine into RNA of epidermal cells measured by counting silver grains over sectioned nuclei of 300–600 cells from treated and adjacent control areas of mouse skin

Time after DMBA application (days)	Percentage reduction in grain count (mean ± *S.E.*)
Unwashed	
1	30·4 ± 0·8
3	36·5 ± 1·9
7	28·5 ± 1·4
Washed at 1 h	
1	22·9 ± 2·2
	16·9 ± 1·7

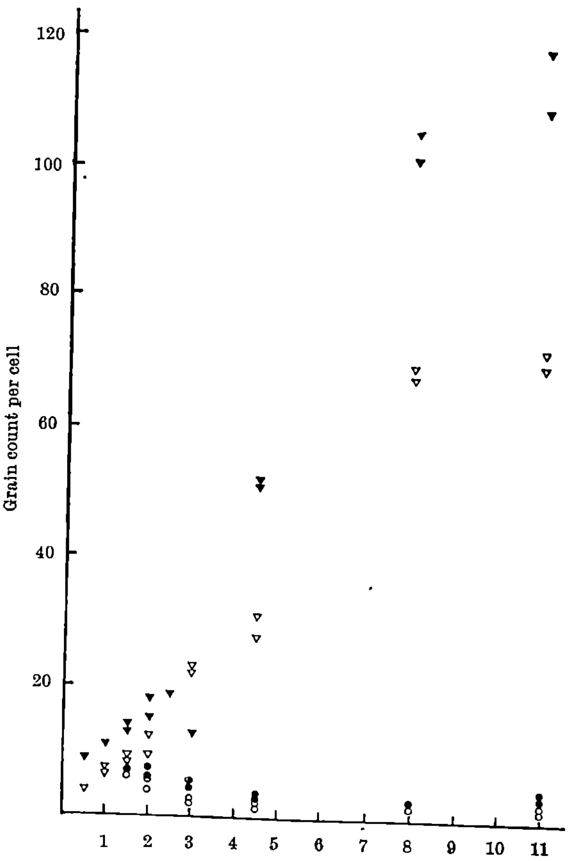

Fig. 1. No. of silver grains per cell is plotted against the time of incubation of the pieces of skin in Tyrode's medium. Triangles represent continuous incubation in Tyrode's medium containing ^{3}H-cytidine. Circles represent incubation for 1 h in Tyrode's medium containing carrier cytidine (100 times the concentration of the radioactive cytidine). Open figures represent values for skin to which DMBA was applied 24 h prior to time zero and solid figures represent values for adjacent untreated skin from the same mouse

The differences in the percentage reduction in grain count between 'washed' and 'unwashed' conditions may be explained by the fact that tissue damage was observed histologically 3–5 days after DMBA treatment in the 'unwashed' experiment, but not in the 'washed' experiment. Earlier observations[11] had suggested that the tissue damage observed after DMBA treatment may be a side-effect unrelated to the initiation of a tumour. On present evidence it is not possible to implicate tissue damage as the factor responsible for the reduction in grain count in the 'washed' experiment. The possibility remains that the effect of DMBA on RNA metabolism may be related to the tumour-initiating effect of the hydrocarbon.

In experiments in which the pieces of skin were changed from ^{3}H-cytidine to excess non-radioactive cytidine at 1 h a comparable percentage reduction in grain count in the 'unwashed' experiments was found (36·9, 44·0 and 33·8 for 1, 3 and 7 days), but not enough determinations were made in the 'washed' experiments to give a reliable answer. These results indicate that there was a reduction in incorporation of ^{3}H-cytidine into the metabolically stable RNA.

The decreased incorporation of ^{3}H-cytidine into RNA could reflect a number of changes including an absolute reduction in synthesis of RNA, increased production and utilization of endogenous precursors over an exogenous supply, more rapid degradation of the radioactive precursors into non-precursor substances, inhibition of phosphorylation of RNA precursors or the activation of an RNA exonuclease leading to breakdown of rapidly labelled RNA[12]. Alternatively, a block in the cytidine deaminase reaction at any level of phosphorylation could allow incorporation of label into the cytidine moiety only instead of into both cytidine and uridine. Because the skin is unfavourable from both a histological and biochemical point of view, this system cannot be used to resolve the possible mechanism of the effect of DMBA on ^{3}H-cytidine incorporation into RNA. Other systems are being investigated with this aim in mind.

Carrier-free (7-^{3}H)-Testosterone

During the course of clinical investigations being carried out here the need arose for tritium-labelled testosterone of very high specific activity. Although 1,2-*tritiated* androgens are available[1,2], their use was precluded in this instance by the extensive loss of radioactivity which would occur during the metabolism of the steroid[3]. Carrier-free (7-^{3}H)-testosterone acetate was prepared by catalytic reduction in pure tritium of 17β-acetoxy-androstan-4,6-dien-3-one.

Δ^6-Testosterone acetate[4,5], m.p. 141·5°–142·5°, $\lambda_{\max}^{\text{EtOH}}$ 284 mμ ($\log\varepsilon = 4{\cdot}40$), $\lambda_{\max}^{\text{KBr}}$ 5·82μ, 6·08μ, 6·22μ, 6·38μ, 8·12μ, was prepared by dehydrogenation of testosterone acetate with chloranil in *tert*.-butanol[4]. The use of 2,3-dichloro-5,6-dicyano-*p*-benzoquinone catalysed with hydrogen chloride[6] gave the dienone more conveniently and in better yield though mixed with about 10 per cent of the 1,2-unsaturated isomer ($\lambda_{\max}^{\text{EtOH}}$ 244 mμ). This was unacceptable because chromatographic separation of testosterone acetate and its Δ^1- and Δ^6-unsaturated derivatives proved very difficult.

The reactivity with respect to catalytic hydrogenation in neutral solution of the steroidal 4,5-double bond is exceeded only marginally by that of the 6,7-double bond[7]. This difference can be increased by conducting the reaction in anhydrous methanol in the presence of a small but critical concentration of alkali[7]. In a preliminary experiment, Δ^6-testosterone acetate (42 mg) in dry methanol containing 400 mg l.$^{-1}$ of potassium hydroxide was shaken with pre-reduced 5 per cent palladium-on-charcoal catalyst (3·3 mg) under hydrogen at 1 atm. pressure, and allowed to consume 1·2 moles of gas. The solution was filtered, acidified with glacial acetic acid and evaporated. The steroid was separated from inorganic material by leaching with dry chloroform and crystallizing from methanol to yield testosterone acetate, m.p. 139°–141°, $\lambda_{\max}^{\text{EtOH}}$ 241 mμ ($\log\varepsilon = 4{\cdot}21$). The mixed melting point with an authentic sample showed no depression. Traces of the 17β-acetoxy-androstan-3-ones were detected in the mother-liquor by vapour-phase chromatography.

Using the foregoing conditions, a 60-mg sample of Δ^6-testosterone acetate was reduced in carrier-free tritium gas to give testosterone acetate showing no selective absorption at 284 mμ in its ultra-violet spectrum. This material was saponified with 0·2 N alkali in aqueous methanol and the resulting testosterone separated from saturated steroids by paper chromatography (Whatman No. 1 paper; 19 : 1 isooctane–toluene/80 per cent aqueous methanol), the zones being detected by autoradiography. The testosterone was eluted from the paper and shown by ultra-violet spectroscopy and carrier-dilution analysis to have a specific activity of 30·8 curies mmole^{-1}. This value is consistent with the formulation of the product as (7-^{3}H)-testosterone, having arisen from the initially formed (6,7-^{3}H$_2$)-testosterone by loss of the 6-tritium atom through enolization.

The tritiation was carried out at the Radiochemical Centre, Amersham, by Dr. E. A. Evans, whom we thank.

Saturated Hydrocarbons from Autoxidizing Methyl Linoleate

Examination of the vapours of autoxidizing methyl linoleate by gas-liquid chromatography has revealed the presence of several compounds with retention times corresponding to methane, ethane, propane, butane and pentane. Identification of these compounds from autoxidation of a purified unsaturated ester has not, to our knowledge, been previously reported. This finding confirms a prediction made by C. D. Evans *et al.* that low-molecular-weight hydrocarbons would be produced by autoxidation of unsaturated fatty acids[1,2]. They also reported saturated and unsaturated short chain hydrocarbons had been found in products from autoxidation of soybean oil[3]. Buttery and associates identified C_1 to C_5 normal saturated hydrocarbons in dehydrated potatoes, in which linoleic acid is the principal unsaturated acid in the lipids[4]. They speculated that the hydrocarbons might have been formed in autoxidizing dehydrated potatoes by hexanal decomposition that had been catalysed by fat peroxides. However, our findings with methyl linoleate show that the saturated hydrocarbons arise early in the autoxidation process, when aldehydes are either absent or present in undetectable amounts. Therefore, the hydrocarbons are being formed either by an extremely rapid decarboxylation of aldehydes present at a low steady-state concentration or by a totally different mechanism. Japanese workers identified ethane and higher molecular weight alkanes and alkenes from air-oxidation of soybean oil at 240° C (refs. 5 and 6). Their results cannot be compared with ours, however, because our ester was relatively pure and our experiments were performed at room temperature.

We chose methyl linoleate as a simplified system for studying rancidification in parboiled wheat products (bulgur), because linoleic acid is the principal unsaturated fatty acid in the lipids of whole wheat[7]. The original purpose of the experiments was to observe the development of carbonyls produced by autoxidation of unsaturated fatty acids in a system free of the complications inherent in bulgur.

We placed 1-g samples of methyl linoleate (98 per cent purity, as analysed by gas-liquid chromatography) on purified glass wool in 50-ml. Erlenmeyer flasks, capped the flasks with aluminium foil, and exposed them to laboratory light at room temperature. Using a gas-tight syringe, we withdrew vapour samples through the foil at intervals and injected the vapour into a gas chromatograph equipped with a dual hydrogen flame detector and a 7-ft. column containing 'Apiezon *M*' on firebrick. Initial vapour samples showed only the usual air peak. As autoxidation proceeded, we observed sharp peaks possessing much lower retention times than any authentic aldehyde, ketone, or alcohol. These compounds produce wide peaks accompanied by some tailing. The sharpness of the unidentified peaks suggested that they were saturated hydrocarbons. These sharp peaks began to appear after the ester had been exposed to air less than 24 h, long before hexanal, pentanal, or higher molecular weight carbonyls appeared.

Further confirmation of the saturated nature of the compounds was obtained by shaking 10 ml. of the vapour from the autoxidizing methyl linoleate with 1 ml. of concentrated sulphuric acid, which should absorb any olefines or oxygen-containing compounds. Only three symmetrical peaks persisted in the chromatograms after the sulphuric acid treatment. Two of these peaks were tentatively identified as butane and pentane by retention times. The 'Apiezon' column, which had been chosen for its ability to separate carbonyls, failed to separate methane, ethane and propane.

In order to determine whether the third peak indeed consisted of methane ethane, and propane, the untreated vapours from autoxidizing methyl linoleate were further analysed on a molecular sieve column. Five peaks possessing retention times corresponding to hydrocarbon standards were present in these chromatograms and persisted after sulphuric acid treatment. Sulphuric acid-treated vapours of autoxidizing methyl linoleate were also run on a capillary column coated with General Electric silicone oil '*SF*–96 (50)'. Because of losses from stream-splitting, only the peak corresponding to pentane was of appreciable size.

In order to eliminate the possibility that the observed hydrocarbons were artefacts, blanks were run with each gas-liquid chromatography analysis. The blanks were prepared by withdrawing the appropriate volume of air from an aluminium foil-capped 50-ml. Erlenmeyer flask containing purified glass wool and then injecting the required volume into the gas-liquid chromatography apparatus. Chromatograms from the blanks showed only the initial air peak, whether or not the sample had been shaken with concentrated sulphuric acid.

The reference compounds, ethane, propane, and butane, were synthesized from the appropriate alkyl bromide by the Grignard reaction. Before use, alkyl bromides were purified by distillation. Methane was prepared by fusing C.P. anhydrous sodium acetate and C.P. potassium hydroxide. Pentane was obtained from a commercial source at a purity of 99 per cent and further purified by fractionation through a 20-plate 'Nichrome' helix-packed column. Each hydrocarbon gas was purified by shaking with concentrated sulphuric acid.

Table 1. IDENTIFICATION OF HYDROCARBONS IN HEADSPACE FROM AUTOXIDIZING METHYL LINOLEATE

	'Apiezon *M*' column*		Capillary column†		Sieve column‡	
	Authentic sample	Autoxidizing ester vapours	Authentic sample	Autoxidizing ester vapours	Authentic sample	Autoxidizing ester vapours
	Retention times (min)					
Methane	—	—	—	—	0·6	0·6
Ethane	—	—	—	—	1·2 4·3§	1·2 4·1§
Propane	—	—	—	—	2·2	2·2
Butane	0·7	0·7	—	—	9·4	9·2
Pentane	1·0	1·0	14·2	14·0	39·5	40·1

* Column, 7 ft. by 1/8 in. outer diam. stainless-steel, containing 10 per cent 'Apiezon *M*' on firebrick; nitrogen exit flow rate, 60 ml./min; column temperature, 100° C; chart speed, 101·6 cm/h.

† Capillary column, 600 ft. by 0·02 in. internal diam. stainless-steel, coated with General Electric silicone oil '*SF*–96 (50)'; helium exit flow rate, 12 ml./min; column temperature, 32° C; chart speed, 30·48 cm/h.

‡ Column, 2·5 ft. by 1/8 in. outer diam. stainless-steel, containing Linde molecular sieve type 5*A*; helium exit flow rate, 33 ml./min; column temperature, 150° C; chart speed, 30·48 cm/h.

§ Column temperature, 35° C.

In Table 1 the retention times of the five hydrocarbons tentatively identified in the vapours of autoxidizing methyl linoleate are compared with those of authentic hydrocarbons. Since ethane is present in the vapours of autoxidized methyl linoleate in an extremely low concentration, this compound may be an artefact produced by autoxidation of some other contaminating unsaturated acid. Pentane is the major component, representing more than 90 per cent of the hydrocarbon fraction.

Work is in progress to substantiate the identity and to determine the mechanism by which these hydrocarbons are formed during the autoxidation of methyl linoleate.

A Second Naphthoquinone in Spinach Chloroplasts

DURING the chromatography of lipids from spinach chloroplasts we have observed a compound which appears to be a form of vitamin K which is different from the well-known vitamin K_1. The latter has previously been isolated from chloroplasts[1,2] and is widely distributed in green plants[3].

This second naphthoquinone has been isolated by extracting spinach chloroplasts (about 1,500 mg chlorophyll) with a heptane–propanol mixture[4]. The extract is chromatographed on a 'Decalso' column with heptane, 10 per cent ether in heptane, and ethanol as the eluants. The 10 per cent ether fraction is then re-chromatographed on a 3 : 1 w/w 'Supercell' silicic acid column (5 cm × 25 cm). By eluting with heptane and collecting 10 ml. aliquots, the naphthoquinone can be seen within the first 30 fractions immediately following vitamin K_1. The ultra-violet spectrum of the purified compound (Fig. 1) is similar to the vitamin K_1 and K_2 homologues except that the 269 mμ peak is absent. In this respect the new compound very much resembles the demethylated form of vitamin K_1 isolated by Baum and Dolin from *Streptococcus faecalis*[5]. Also the addition of the ethyl cyanoacetate anion gives a positive Craven's test in the presence of sodium hydroxide which would indicate a demethylated compound[6]. The new quinone shows

Table 1. CHROMATOGRAPHIC PROPERTIES OF THE NAPHTHOQUINONE AND DIFFERENT TYPES OF VITAMIN K

	Quinone	R_F in silica gel '*H*' Benzene	30% ether in isooctane
1	New naphthoquinone	0·56	0·62
2	Vitamin K_1	0·69	0·65
3	Vitamin K_2 (C10)	0·56	0·54
4	Vitamin K_2 (C20)	0·63	0·59
5	Vitamin K_2 (C30)	0·69	0·61
6	Coenzyme Q_{10}	0·39	0·37
7	Plastoquinone *B*	0·80	0·79
8	1 and 2	0·56 and 0·71	0·63 and 0·67

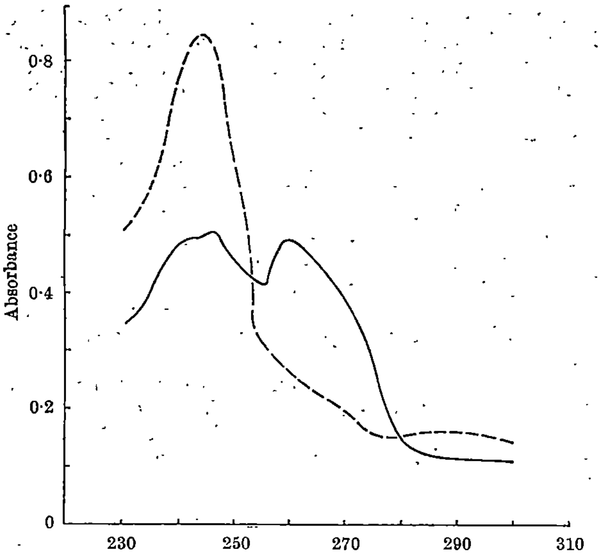

Fig. 1. Spectrum of new naphthoquinone in ethanol. ——, Oxidized form; – – –, after reduction with borohydride

different chromatographic properties from vitamin K_1 on thin-layer silica gel '*H*' in two different developing systems (Table 1), benzene and 30 per cent ethyl ether in isooctane[7]. The infra-red spectrum in carbon tetrachloride indicates a K_1 compound rather than K_2 based on the analysis of Noll[8].

Using a *millimolar* extinction coefficient of 19, which is characteristic of the vitamin K series[9], a maximum concentration of 0·002 µmoles/mg chlorophyll has been observed. From previous investigations of the specificity of naphthoquinones in assays of vitamin K activity it can be predicted that this compound would be difficult to detect in biological assays for vitamin K in plant material[10].

This is the ninth quinone to be found in spinach chloroplasts[4], and its presence should be considered in any of the investigations of restoration of biological activity after solvent extraction.

We thank Dr. O. Isler of F. Hoffman La Roche Co. for providing samples of vitamin K for chromatographic comparison. This work was supported in part by U.S. National Science Foundation grant *G*567.

Cellulase in Tomato Fruits

There are only a few reports of enzymes from higher plants which can hydrolyse cellulose or water-soluble cellulose derivatives. Several reports show that malt extracts are capable of hydrolysing water-soluble cellulose derivatives[1,3,11] and dispersed cellulose fibres[1,7]. A malt extract was found to hydrolyse reprecipitated cellulose more rapidly than a similar extract from barley seeds[1]. There is a single report that potato sprouts hydrolysed the cellulose in cardboard[8]. Another report[10] showed that sap from tobacco leaves and roots hydrolysed carboxymethylcellulose and reprecipitated cellulose. In addition to tobacco, cellulase was found on single occasions in bean leaves, roots of beet and woody nightshade, asparagus stems, and the flesh of vegetable marrow fruit. The enzyme was not detected in tomato fruits or rhubarb petioles which had *p*H values of 4·3 and 3·4 respectively. The author mentioned that the *p*H was greater than 5 in all the saps in which activity was found.

Although cellulase has not been reported in fleshy fruits[9], changes are known to occur in fruits during ripening which could be caused by cellulase activity. α-Cellulose decreased in ripening pears[2], and the diameter of the cellulose micelles in peaches increased during ripening[9]. The increase in diameter could have been caused by limited degradation of cellulose microfibrils in the amorphous regions.

This communication reports the presence of an enzyme in tomato fruits which depolymerizes carboxymethylcellulose. A method of extracting the enzyme, in which *p*H is particularly important, is described. Enzyme assays were carried out using Ostwald viscosimeters. The reaction mixture in the viscosimeter contained 1 per cent carboxymethylcellulose ('CMC-7M', Hercules Powder Co.), 0·1 N sodium acetate, *p*H 5·0, 0·01 per cent merthiolate, and 2 ml. enzyme in a final volume of 10 ml. Enzyme activity was expressed in cellulase units. One cellulase unit is the amount of enzyme causing an increase in $1/\eta_{sp}$ (reciprocal of the specific viscosity) of 1 per min[4]. Initial preparations were made using methods similar to those used for extracting pectic enzymes[5,6]. Ripe unblemished tomatoes were homogenized 2 min, 100 V in a Waring blender with sufficient sodium chloride to give a 10 per cent solution. Merthiolate (0·01 per cent) was added immediately after homogenizing, and the *p*H was adjusted to 8·0 with 1 N sodium hydroxide. Solids were removed by centrifuging and filtering. The filtrate reduced the viscosity of 'CMC-7M' at *p*H 5·0 from approximately 13·5 to 6 centipoises in 5 h. The relation between $1/\eta_{sp}$ and time seemed linear until the viscosity dropped below approximately 9 centipoises, so cellulase activity was calculated from the linear part of the curve. Assays were conducted at *p*H 4, 5, 6 and 7·5. *p*H 5·0 gave the highest activity, and that *p*H was used in subsequent assays. Merthiolate (0·01 per cent) did not affect activity. Complete inactivation resulted when 2·5 ml. of filtrate at *p*H 7·0 was placed in boiling water for 15 min in a 1-cm diameter test-tube. There was a marked difference in enzyme activity between mature green and ripe fruits. Filtrate from a sample of 5 mature green fruits contained 9 µunits/ml., while filtrates from 5 similar samples of ripe fruits contained 93–174 µunits/ml.

The importance of raising the *p*H and the need for sodium chloride were investigated using a homogenate from ripe fruits. A portion of the homogenate was made 10 per cent in sodium chloride. Six 70-g samples of homogenate were taken, 3 containing sodium chloride and 3 having no sodium chloride. The 3 samples containing sodium chloride were adjusted to *p*H 6·0, 7·0 and 8·0 respectively. The samples lacking sodium chloride were treated in the same way. The yield of enzyme was decreased by sodium chloride, and it was increased by each increment of *p*H (Table 1). The *p*H 7·0 filtrate, which lacked sodium chloride, was made 10 per cent in sodium chloride and assayed again. Cellulase activity was unchanged so the salt did not act as an inhibitor.

The effect of neutralization is also shown in Figs. 1 and 2. Dulpicate 70-g samples were taken from a homogenate of ripe fruits. One sample was titrated to *p*H 8·0, and the other remained at *p*H 4·2. Filtrate from the neutralized sample contained 1,130 µunits/ml. uncorrected for the addition of sodium hydroxide, while that from the unneutralized sample contained 68 µunits/ml.

Table 1. Effect of Extraction Method on Yield of Cellulase

Homogenate titrated to *p*H	Cellulase activity* (μunits/ml. filtered tomato extract) 10% NaCl	No NaCl
6·0	46	540
7·0	100	680
8·0	260	810

* Each value represents enzyme activity from a different sample.

Ripe, unblemished tomatoes were homogenized 2 min at 100 V in a Waring blender. Three samples were obtained from part of the homogenate which had been made 10 per cent in NaCl. These samples, and 3 others which lacked NaCl, were titrated to the given *p*H with 1 N NaOH. The samples were centrifuged and filtered and cellulase activity in the filtrate was determined.

Table 2. Elution of Cellulase from the Insoluble Fraction

	Treatment	Volume of supernatant (ml.)	Cellulase activity (μunits/ml.)	Recovery (% of control)
1.	Control, titrated to *p*H 8·0	62·0	805	100
2.	Sample, *p*H 4·2			
A	Supernatant, *p*H 4·2	52·0	53	12
B	Distilled water rinse	68·5	27	
C	,, ,, ,,	71·0	22	
D	0·04 M sodium citrate, *p*H 8·0	66·0	271	75
E	,, ,, ,, ,,	63·5	156	
F	,, ,, ,, ,,	61·5	143	
G	0·5 M ,, ,, ,,	34·6	23	

Firm ripe fruits were homogenized in a Waring blender at 100 V for 2 min. Two 70-g samples were taken from the homogenate, and one was titrated to *p*H 8·0. The insoluble fraction was removed by centrifugation, and the pellet from the unneutralized sample was resuspended successively in solutions *B*–*G*. Cellulase activity was measured in the supernatants.

The values were equivalent to 950 and 18 μunits/g fresh weight. Thus, in the unneutralized sample, 94 per cent of the enzyme remained adsorbed to the insoluble fraction, and activity in the filtrate was extremely low. In another experiment with ripe fruits (Table 2), a portion of unneutralized homogenate was centrifuged, and the insoluble fractions were precipitated by centrifugation. The solids were suspended in distilled water and precipitated. The procedure was repeated with a second portion of distilled water and again with portions of citrate buffer at *p*H 8·0. Most of the enzyme remained adsorbed to the insoluble fraction and was not brought into solution until extraction with the citrate buffer. The results suggest that cellulase could be concentrated by pressing the juice from a large sample of fruits and extracting the insoluble fraction with small volumes of alkaline buffer. Work is in progress to concentrate the enzyme and determine whether it can hydrolyse substrates other than carboxymethylcellulose.

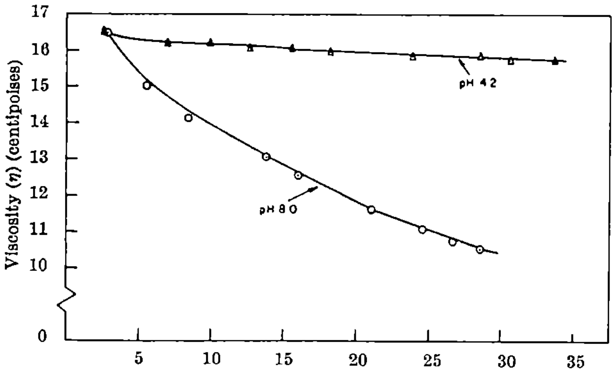

Fig. 1. Effect of tomato extracts on viscosity of carboxymethyl-cellulose ('CMC-7M'). Firm ripe fruits were homogenized 2 min, 100 V in a Waring blender. Two 70-g samples were taken and one sample was titrated to *p*H 8·0 with 5·0 ml. N NaOH. The other sample remained at *p*H 4·2. The insoluble fraction was precipitated by centrifuging, and cellulase activity was measured in the supernatant fluid

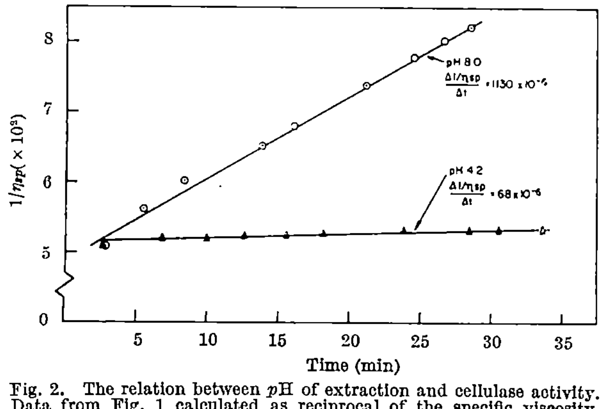

Fig. 2. The relation between *p*H of extraction and cellulase activity. Data from Fig. 1 calculated as reciprocal of the specific viscosity. One unit of enzyme activity represents a change in $1/\eta_{sp}$ of 1 per min

Neutralizing may also be necessary for efficient extraction of cellulase from other plant tissues characterized by low *p*H. The *p*H may also be important for tissues which are low in acids, since 50 per cent more enzyme was obtained by raising the *p*H of tomato homogenates from 6 to 8.

Since cellulase activity increases during ripening, the enzyme may be involved in the ripening process. Although its substrate specificity is not yet known, cellulase may act in conjunction with pectic enzymes to cause softening in ripening tomatoes.

Prevention by 2,4-Dichlorophenoxyacetic Acid of an Increase in the Rate of Phosphate Utilization, caused by the Prolonged Treatment of Segments of Pea Stems in Maleate Buffer

While examining the influence of 2,4-dichlorophenoxyacetic acid (2,4-D) on the absorption of ions by epicotyl segments of etiolated peas, it was established that if freshly cut segments are first placed in aerated, distilled water or 0·01 M maleate buffer (*p*H 5·2) for 12 h, their ability to absorb and esterify inorganic phosphate in a given time (1 h) is increased 12-fold. This marked increase in the rate of phosphate absorption necessitated further study before the effects of 2,4-D on the uptake of ions could be further elucidated. On the basis of this work, which has been reported elsewhere[1], it is concluded that one of the basic changes occurring in the segments during the period in buffer or water is an increase in the rate of synthesis of protein, which in turn results in an increased rate of absorption of phosphate. An increased turnover of protein when pea segments were placed in water for 24 h was reported by Christiansen and Thimann[2] in 1950. Recently, Click and Hackett[3] have suggested that the increased respiratory rate and other metabolic changes occurring when potato slices are similarly treated depend on the synthesis of new RNA and protein.

It has now been demonstrated that the changes with time in the rate of absorption of phosphate can be prevented if the fresh segments are placed in maleate buffer containing 2,4-D. The results given in Fig. 1 show that the change in the capacity to absorb phosphate is dependent on the concentration of 2,4-D; it is unaffected by $1·5 \times 10^{-5}$ M, but is completely inhibited by 2×10^{-4} M. The results bring out two further points. First, that if fresh segments are placed in 2×10^4 M 2,4-D for 4 h and are then transferred to maleate buffer, their ability to absorb phosphate starts to increase. Secondly, that the transfer of segments from maleate buffer to 2×10^{-4} M 2,4-D at 8 h arrests the further absorption of phosphate, but does not bring about a significant decrease.

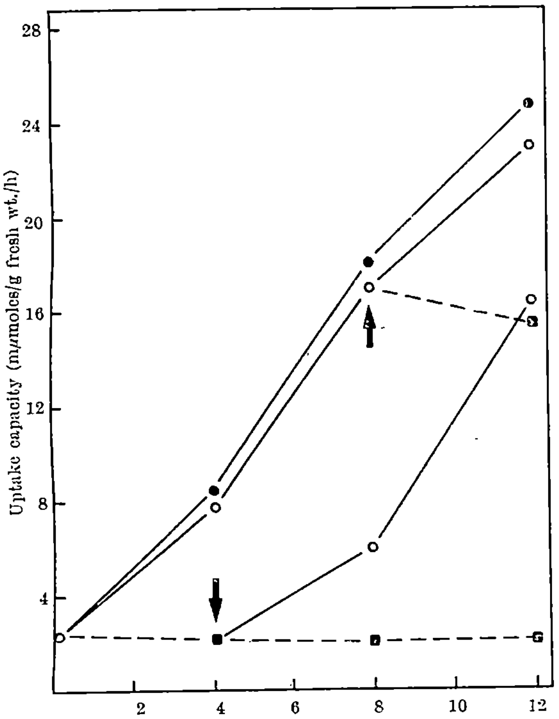

Fig. 1. The effects of placing freshly cut segments (1·0 cm) of pea epicotyls in 0·01 M maleate buffer adjusted to *p*H 5·2 (○) or buffer containing 2,4-dichlorophenoxyacetic acid (2,4-D) at (*a*) $1·5 \times 10^{-5}$ M (●) or (*b*) 2×10^{-4} M (▦ – – ■) on their subsequent capacity to absorb during 1 h phosphate from 1×10^{-3} M KH_2PO_4. The arrows indicate when segments were transferred from 2×10^{-4} M 2,4-D to maleate buffer at 4 h, or from buffer to the same concentration of 2,4-D at 8 h

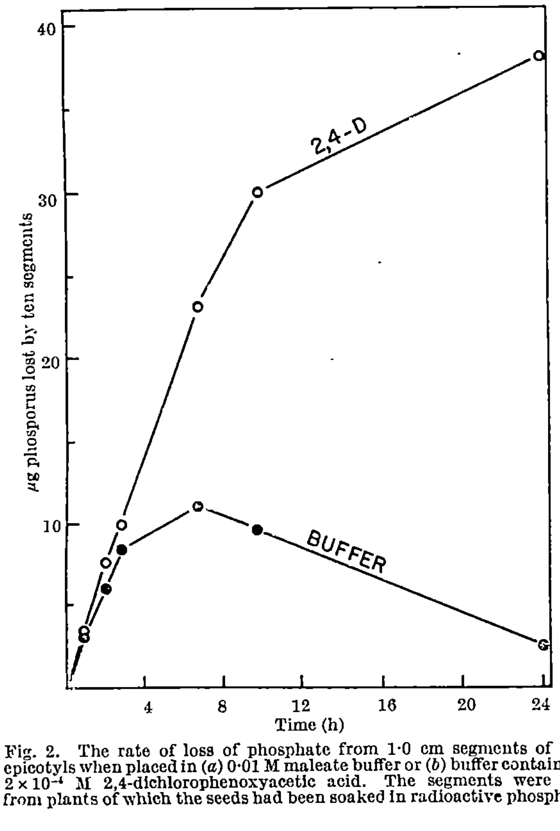

Fig. 2. The rate of loss of phosphate from 1·0 cm segments of pea epicotyls when placed in (*a*) 0·01 M maleate buffer or (*b*) buffer containing 2×10^{-4} M 2,4-dichlorophenoxyacetic acid. The segments were cut from plants of which the seeds had been soaked in radioactive phosphate

Another series of experiments was carried out to determine whether there were substantial losses of phosphorus, as inorganic phosphate, from the segments during the period in buffer, since if this were so, a large depletion of the pool of the endogenous phosphate would predispose the tissues to absorb exogenous phosphate.

From Fig. 2, it is clear that segments placed in maleate buffer lose phosphate rapidly during the first 2 h, but, afterwards, as the capacity to take up phosphate increases, much of the phosphate is re-absorbed. On the other hand, segments placed in 2×10^{-4} M 2,4-D lose phosphate progressively throughout the experimental period, and over the 24 h, the amount lost represents about 40 per cent of the total phosphorus originally contained by the segments.

Since phosphate absorption is seemingly related to an increase in the rate of protein synthesis[1] a reasonable extension is to postulate that 2,4-D prevents these changes by regulating, in some way, the rate of synthesis of proteins.

It is also evident that these significant biochemical changes must be taken into account when designing and interpreting experiments relating to the effects of auxins on the growth of excised stem tissues.

PHYSIOLOGY

Teratogenic Risks of Drug Synergism

It is well known that the effectiveness of teratogens, measured either in incidence or in severity of resulting malformations, is frequently modified, in a plus or minus direction, by unrelated external conditions. The mechanisms by which these modifying agencies operate are largely unknown. A little, if not a great deal more, is known about the role of drug interaction in teratogenesis. There are, for example, the facts of interference with essential metabolites, such as deprivation of available vitamins by competing analogues[1] or by blockage of their utilization in co-enzyme systems[2]. Then there are the potentiating effects of lowering the available sources of utilizable carbohydrates[3] or of uncoupling oxidative phosphorylation[4]. Among the latter sources of synergism we found compounds, for example, 2-deoxy-D-glucose and chlorpromazine, which when administered alone were non-teratogenic and which even in larger (and highly toxic) amounts did not produce malformations. Other compounds of this type, however, are themselves teratogenic, in dosages higher than those required for synergism, but the range of their interference with development may be more restricted than their synergistic activity.

In the present enquiry we set out to determine if two compounds, which lead to related malformations when administered singly and in the requisite dosages, will interfere with normal development when individually harmless amounts are used in combination. The compounds selected for these experiments were sulphanilamide and 6-aminonicotinamide, both of which act as teratogens in chick development, inducing the occurrence of similar, though not altogether identical, forms of micromelia and beak defects[1,5,6]. The results of duplicate tests are given in Tables 1 and 2. It can be seen that the administration of 300 γ sulphanilamide or of 1·5 γ 6-aminonicotinamide was non-toxic and a high percentage of the treated embryos lived to hatching. The hatching percentages in the first test were, in fact, extraordinarily high; in the second experiment the relative hatches were somewhat lower, due to atmospheric conditions of the advancing season, but still very good. In the two experiments in which only sulphanilamide was used, 294 embryos survived the 13th day of incubation; 99 per cent of these were normal, none had micromelia or an abnormal beak. Among 297 embryos which after treatment with 6-aminonicotinamide reached the age of 13 days, 99·3 per cent were normal, none had micromelia and only one (0·3 per cent) had a parrot beak. To the entire harmlessness of the two compounds, in the dosages used, the data for combined administration of the same amounts form a truly dramatic contrast. The two tests yielded very similar results. Hatching was greatly reduced in both experiments. Instead of 99 per cent or more of the survivors of the 13th day being normal, only 20·7 per cent of a total of 275 embryos were without gross defects; 78·9 per cent of the embryos and chicks were micromelic, with many showing an extreme and crippling form of micromelia; 63·6 per cent of the embryos and chicks diagnosed in the two tests showed a parrot beak or a shortening of the mandible; finally, 18·0 per cent of 183 chicks, which had hatched in the two tests with combined treatment, exhibited ataxia and chorea.

Table 1. The Effects of Sulphanilamide and 6-Aminonicotinamide injected, singly or in combination and at 96 Hours of Incubation, on Development of White Leghorn Chicks. March 1964

Sulphanilamide γ/egg	300	300	—
6-Aminonicotinamide γ/egg	—	1·5	1·5
No. treated	106	108	105
Mortality (%)			
To end 6th day	2·8	7·4	4·8
7–13	1·9	2·8	1·0
14–22	5·7	18·5	1·0
Hatched (%)	89·6	71·3	93·3
Survivors of 13th day	101	97	99
Normal (%)	99·0	19·6	100
Micromelia (%)	0	80·4	0
Parrot or short lower beak (%)	0	55·7	0
Ataxia and chorea among hatched (%)	0	11·7	0
Miscellaneous defects (%)	1·0	0	0

Table 2. Repetition of Experiment recorded in Table 1, May 1964

Sulphanilamide γ/egg	300	300	—
6-Aminonicotinamide γ/egg	—	1·5	1·5
No. treated	212	206	219
Mortality (%)			
To end 6th day	8·0	11·7	7·8
7–13	0·9	1·9	1·8
14–22	12·3	35·0	9·1
Hatched (%)	78·8	51·5	81·3
Survivors of 13th day	193	178	198
Normal (%)	99·0	21·3	99·0
Micromelia (%)	0	78·1	0
Parrot or short lower beak (%)	0	68·0	0·5
Ataxia and chorea among hatched (%)	0	22·6	0
Miscellaneous defects (%)	1·0	2·8	0·5

After the administration of highly teratogenic amounts of sulphanilamide or 6-aminonicotinamide (1 mg and 10 γ/egg, respectively), the forms of expression of micromelia and beak defects tend to show subtle distinctions although their ranges overlap widely. Mean body-size is reduced after either treatment, but the dwarfing is usually more extreme following injection of 6-aminonicotinamide. In our present results, obtained by combined administration of the two compounds, the skeletal symptoms (long bones, maxilla and mandible) partake of the whole range of abnormalities observed after separate injection of the two teratogens. There was, however, little, if any, reduction in body-size even in severely micromelic chicks. The occurrence of ataxia and chorea in this material is of interest since these are symptoms of nervous dysfunction which occur following the administration of larger amounts of 6-aminonicotinamide, but have never been observed in experiments with sulphanilamide.

The relatedness of the induced defects and the possibility of complete protection with supplements of nicotinamide indicate that the intra-embryonic effects of sulphanilamide and 6-aminonicotinamide pertain to a particular chain of metabolic events and its end-product. There is also evidence, however, in addition to the slight dissimilarities of phenotype to which reference has been made, that different steps within this chain are affected by the two compounds. This is strongly suggested by the fact that 2-deoxy-D-glucose is a potent synergist of the teratogenic activity of 6-aminonicotinamide, but does not potentiate the results of injected sulphanilamide.

It is clear from the foregoing that altogether harmless amounts of potentially teratogenic substances may in combination produce powerful synergism and thereby a high incidence of severe malformations. Moreover, we have demonstrated in earlier experiments that non-teratogenic compounds may also act as highly effective synergists. The cautionary consequences of these facts should not require emphasis.

Our work was supported by a grant from the National Science Foundation.

We wish to dedicate the present observations to the memory of that wise and courageous woman—Rachel Carson.

Blood Velocity telemetered from Untethered Animals

The magnitude of the change in frequency of sound back-scattered in moving blood is a measure of the velocity of the blood[1,2]. We have used this principle to design a system for telemetry of blood flow information from the major vessels of healthy, active, totally unrestrained animals.

Cylindrical plastic flow probes were clamped around blood vessels during an aseptic surgical procedure. A piezo-electric crystal (lead zirconate) mounted in one wall of the cylinder emitted a continuous 5-Mc/s sound beam diagonally through the blood vessel wall into the centre of the blood stream. A second piezo-electric crystal, mounted in the opposite wall of the cylinder, served as a sensor for the sound back-scattered from within the blood stream (Fig. 1). The magnitude of the difference in frequency between the emitted sound and the back-scattered sound was proportional to the velocity of the blood within which the sound was scattered, as described by the Doppler equation:

$$(F_e - F_r) = F = \frac{2\, F_e\, v \cos a}{C}$$

where: F = absolute difference in frequency between emitted signal frequency, F_e, and the received signal frequency, F_r.
v = velocity of scattering medium.
a = angle between acoustical axes and blood velocity.
C = velocity of sound in blood.

For typical application :
$F_e = 5 \times 10^6$ c/s
$C = 1{\cdot}5 \times 10^5$ cm/sec
$\cos a = 0{\cdot}7$
v ranges from 0 to 150 cm/sec so that F ranges from 0 to approximately $7{\cdot}5 \times 10^3$ c/s.

An electrical signal was developed with a frequency equal to the Doppler shift between the emitted and back-scattered signals. This audio-frequency signal modulated the frequency of a 100-Mc/s oscillator. The resultant

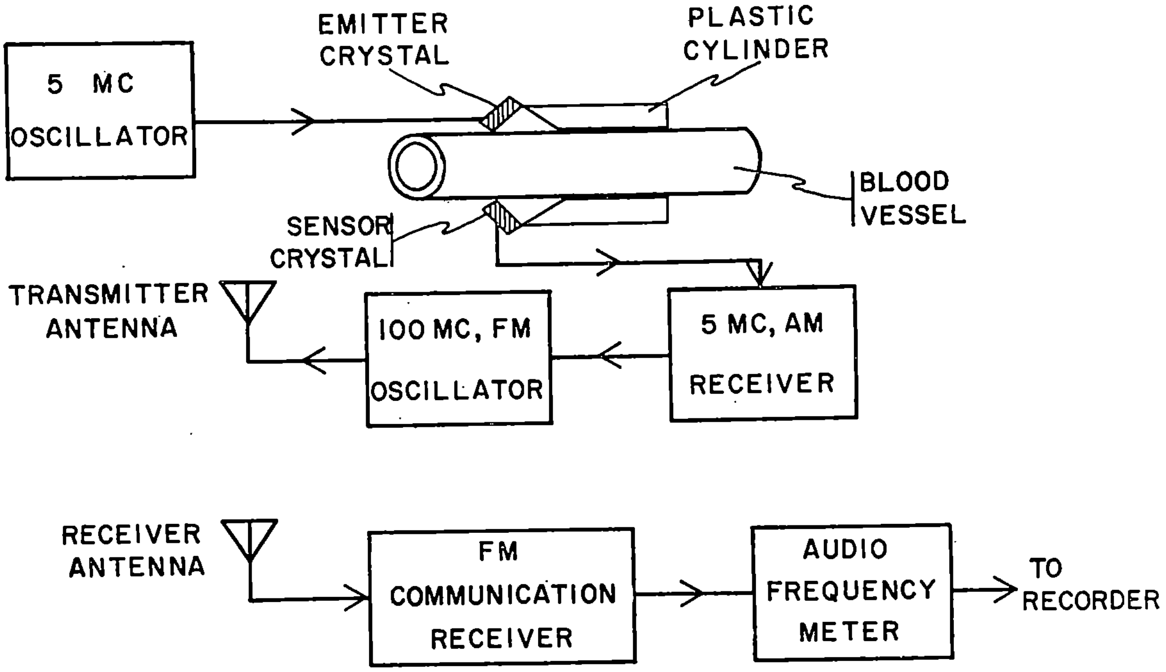

Fig. 1. Block diagram of method for telemetry of blood flow information using Doppler shift ultrasonic flowmeter

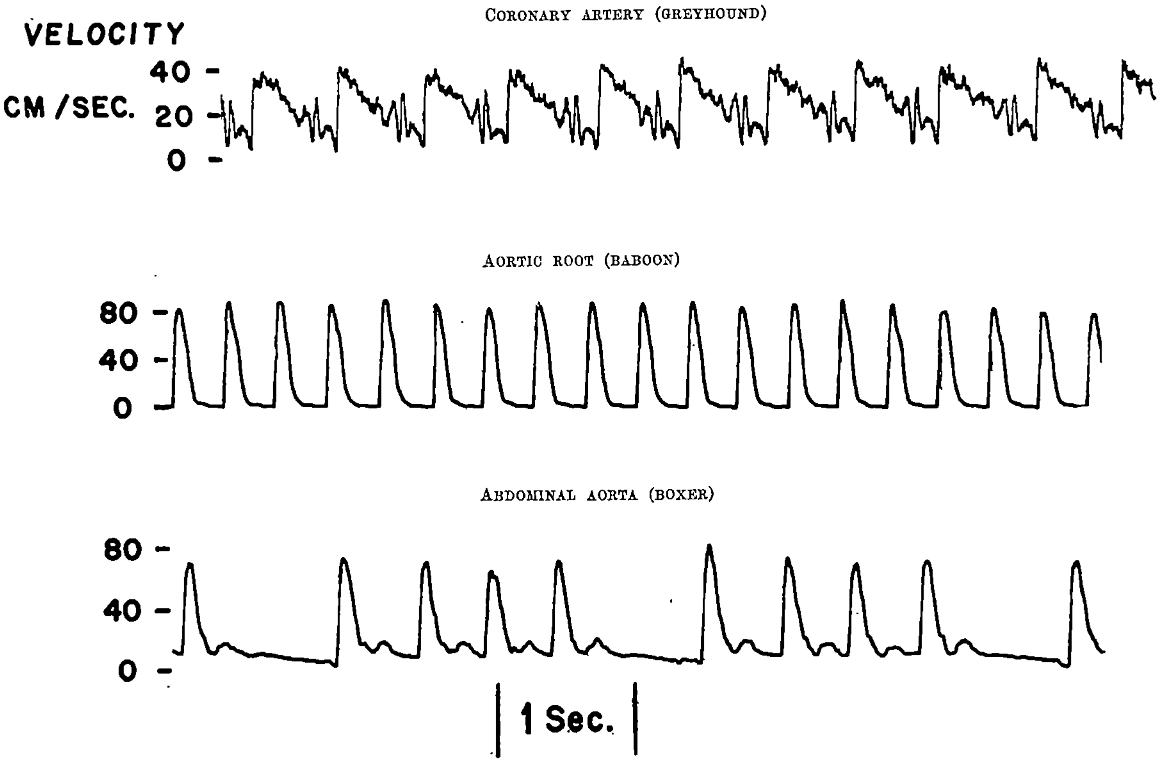

Fig. 2. Representative wave forms of flow telemetered from untethered animals: circumflex arterial flow in walking greyhound; flow through the root of the aorta in an exercising baboon; and flow through the terminal abdominal aorta in a somnolent boxer

FM/FM signal was transmitted from the animal to a remote frequency modulation tuner. The audio-frequency signal from the tuner was coupled to a frequency meter, and the voltage from the frequency meter was recorded in terms of blood velocity.

The emitter crystal was excited by a miniature (2 cm × 1·5 cm × 1·5 cm) 5-Mc/s oscillator, with a power consumption of 100 mW. The acoustical power was estimated to have been less than 200 mW/cm^2. A miniature (2 cm × 2 cm × 9 cm) low-noise, tuned radio-frequency receiver was used to amplify and detect the back-scattered signal. The power consumption of the receiver-amplifier was 30 mW. The 100-Mc/s oscillator-transmitter consumed 50-mW power. Its size was 2 cm × 2 cm × 6 cm. The entire assembly was powered by two Mallory *TR* 136 *R* batteries and had a continuous operating time of

100 h. When used in animal experiments, the components were assembled into a small packet which was carried on a harness (dogs, seals) or built into a plastic helmet (baboons). A simple loop of wire served as the transmitting antenna. The *FM* receiver was a standard 'Hi-Fi' tuner located as much as 300 m away from the experimental animal.

Zero flow-levels were obtained by opening the input to the frequency meter. This procedure has previously been demonstrated to simulate occlusion of the vessel ($F_e = F_r$, $F = 0$) and yields a reliable measure of zero flow levels[1,2]. The frequency meter was calibrated against an audio-frequency standard and the blood velocity was computed using the Doppler equation.

We have used the Doppler sonic blood flow telemetry system for measurement of blood flow through the major arteries of free ranging dogs, and the ascending aorta of baboons in an outdoor enclosure. In addition, we have measured blood flow through the carotid, iliac and flipper arteries of elephant seals in their natural habitat on Guadalupe Island off the coast of Mexico. In the latter case, blood flow was telemetered from animals on the beach to recording instruments on a research ship situated 200 m off shore. In another application, blood flow through the ventral aorta of sharks swimming in the ocean was telemetered to recording instruments on shipboard.

The Doppler shift sonic method for measurement of blood flow has proved to be well suited for telemetry of flow information from violently exercising, untethered animals. The simplicity and low-power consumption of the system are compatible with the small packaging requirements of telemetry from animals. The instrument is free of base-line drift. Drift in sensitivity is proportional to drift in the crystal excitation frequency, which can be held essentially constant, and to variations in the velocity of sound in blood which have been found to be negligible. The flow information from the 5-Mc/s receiver-amplifier is in the form of a frequency modulated, audio-frequency signal, which allows the use of standard *FM/FM* telemetry techniques without the necessity of including a separate sub-carrier oscillator.

This work was supported by U.S. Public Health Service grants *HE*-08337, *HE*-08433, and *HE*-08323. The elephant seal experiments were part of a combined examination of the cardiovascular adaptation to diving carried out on Guadalupe Island under the direction of P. F. Scholander of Scripps Institution of Oceanography. We thank the Institute for Comparative Biology of the San Diego Zoological Society for the use of their laboratories and facilities.

Hyperpolarizing Action Potentials recorded from the Œsophagus of *Ascaris lumbricoides*

THE œsophagus of *Ascaris* is a stout cylindrical organ up to 7 mm in length and more than 1 mm in diameter, which in fresh preparations is often seen to contract rhythmically. Vigorous contractions are also elicited by brief electric pulses applied directly to its surface.

Goldschmidt[1] demonstrated, sixty years ago, that although 33 cells build up the œsophagus, their boundaries are lost. Therefore, the entire organ may be regarded as a tubular, multinucleated, single cell. In cross-sections short bundles of myofibrils are seen to extend between the tri-radiate lumen and the external surface[2].

If a capillary glass microelectrode is inserted into the wall of a quiescent œsophagus, a steady potential of up to 10 mV is recorded between the cytoplasm and the external solution (cytoplasm negative). In contrast to this small resting potential the contractions of the œsophagus, both spontaneous and those which follow applied stimuli, are accompanied by slow, all-or-nothing, action potentials up to 110 mV in amplitude.

Although the shape of these action potentials resembles those recorded from many other cells their polarity is most unconventional. The main initial phase is a large negative deflexion which increases the potential difference across the surface of the œsophagus to a maximal peak value of about 100 mV.

Fig. 1 shows three such action potentials superimposed on the same frame of film. While the rising, that is, hyperpolarizing, phase is smooth and relatively fast (maximal rate of potential change about 10 V/sec) the falling phase is slower and more complex. A fairly

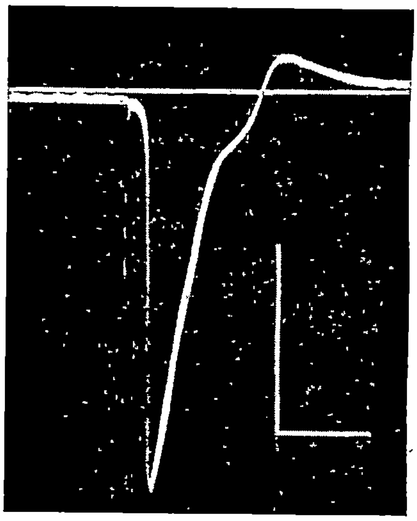

Fig. 1. Three superimposed action potentials recorded with a capillary microelectrode inserted in the wall of *Ascaris* œsophagus. The horizontal line shows the zero base-line. Downward deflexion of the trace indicates negativity of the microtip with respect to the bath electrode. The action potentials were elicited by three brief electric pulses of increasing strength, see artefacts. Vertical bar: 40 mV; horizontal bar: 0·1 sec

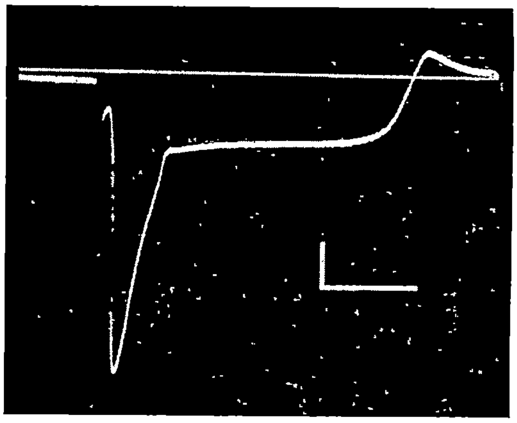

Fig. 2. Action potential recorded from *Ascaris* œsophagus. It differs from those in Fig. 1 by the shelf in the falling, that is, depolarizing, phase (see text). Vertical bar: 10 mV; horizontal bar: 0·1 sec. Horizontal line indicates the zero base-line

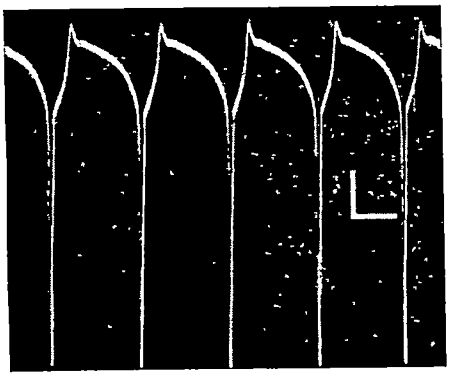

Fig. 3. Rhythmic action potentials recorded from an *Ascaris* œsophagus which exhibited spontaneous mechanical activity. Marked prepotentials are seen to precede each negative spike. Vertical bar: 10 mV; horizontal bar: 1 sec

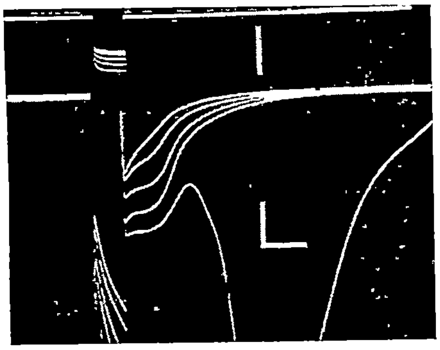

Fig. 4. Negative-going local responses following the injection of inward (that is, hyperpolarizing) membrane current into the œsophageal wall. Upper trace monitors the applied current; vertical bar: 10^{-6} amp. Lower trace shows the potential recorded between the microtip inserted into the œsophageal wall and the bath electrode. The largest local response gave rise to an action potential which flared up 30 msec after the end of the current flow. Vertical bar: 5 mV; horizontal bar: 20 msec

constant feature is the occurrence of a sudden decrease in the rate of depolarization before the potential reaches the initial base-line (Fig. 1). Frequently, the process of depolarization may come to a complete standstill at this point and, as a consequence, a plateau or shelf lasting up to 3–4 sec is observed (Fig. 2).

From this level, the potential does not return directly to the resting value but undergoes a phase of reversed polarity reminiscent of a negative after-potential. This brief positivity of the cytoplasm appears in the records as a small peak of rather constant amplitude, about 10 mV. Thereafter, the potential returns very slowly to the initial base-line; half-decay times of up to 0·8 sec have been measured.

The position of the microelectrode tip within the œsophageal wall is not very critical and it can be shifted radially over distances of 200 or 300 µ without producing appreciable changes in the amplitude of the action potential.

The spontaneous rhythmical contractions of the œsophagus are accompanied by trains of similar action potentials in which the negative spikes are often preceded by marked prepotentials; a mirror-image of those recorded from neural and muscular pacemakers (Fig. 3).

Other experiments, to be described in full elsewhere, have shown that the injection of current into the œsophageal wall with help of a micropipette gives rise to electrotonic potentials which spread decrementally over the giant cell. Action potentials are elicited by a sufficiently large flow of inward, that is, hyperpolarizing, current across the surface of the œsophagus.

A further mirror-image correspondence between the œsophageal action potentials and conventional excitation processes is the occurrence of negative sub-threshold local responses. These are particularly clear-cut following brief anelectrotonic potentials (Fig. 4).

Hyperpolarizing responses with an overall shape resembling the potentials described here have been described by several authors (cf. Grundfest[3]). However, such responses were obtained during the injection of polarizing current into cells immersed in modified ionic solutions. In contrast, the negative spikes found in the œsophagus of *Ascaris* are spontaneous and self-propagating events. When elicited by external stimuli of just threshold strength they are seen to flare up with a considerable latency after the end of the stimulus artefact (Fig. 4).

In all the experiments described here, the œsophagus was immersed in 30 per cent sea-water (v/v); a solution isotonic with *Ascaris* tissues the ionic composition of which resembles that of the perienteric fluid of the worm. Somatic muscle cells of *Ascaris* surrounded by this saline exhibit a conventional electrical behaviour[4,5].

An interesting similarity also exists between the slower œsophageal action potentials, showing a shelf (Fig. 2) and the hyperpolarizing potentials recorded by Brown and Wiesel[6], from the cat's retina.

Although one cannot exclude the possibility that the foregoing findings may be the result of bizarre structural factors yet to be revealed, all the available experimental evidence suggests that we are dealing with action potentials generated across the surface layers of the giant œsophageal cell. In spite of the inverted polarity the electrogenic properties of this cell resemble those of cells producing positive-going, that is, depolarizing, action potentials.

Hepatic Inactivation of Angiotensin

Hypertension induced by renal artery stenosis can be cured in dogs by a reno-portal venous shunt, according to Aoki[1]. A possible explanation is that the affected kidney liberates angiotensin which is in turn inactivated when passing through the liver. The possibility of such inactivation was explored by comparing in rats the pressor response of angiotensin injected through the jugular vein and the portal system.

Twenty-nine Wistar rats, weighing 250–350 g, were anæsthetized with 20 mg/100 g body-wt. of tribromoethanol intraperitoneally and the height of the blood pressure response recorded through the carotid using a Telco strain gauge. 'Hypertensin Ciba' was made up to 2 µg/ml. of saline at *p*H 5·6 or saline adjusted to *p*H 11·7 with sodium hydroxide. Noradrenaline was dissolved in saline, 20 µg/ml. Polyethylene tubing was connected to the jugular vein, the femoral artery or the portal vein (or greater mesenteric). Either 1 µg of angiotensin or 10 µg of noradrenaline was given each time, the injection volume being kept constant at 0·5 ml. (administered within 20 sec).

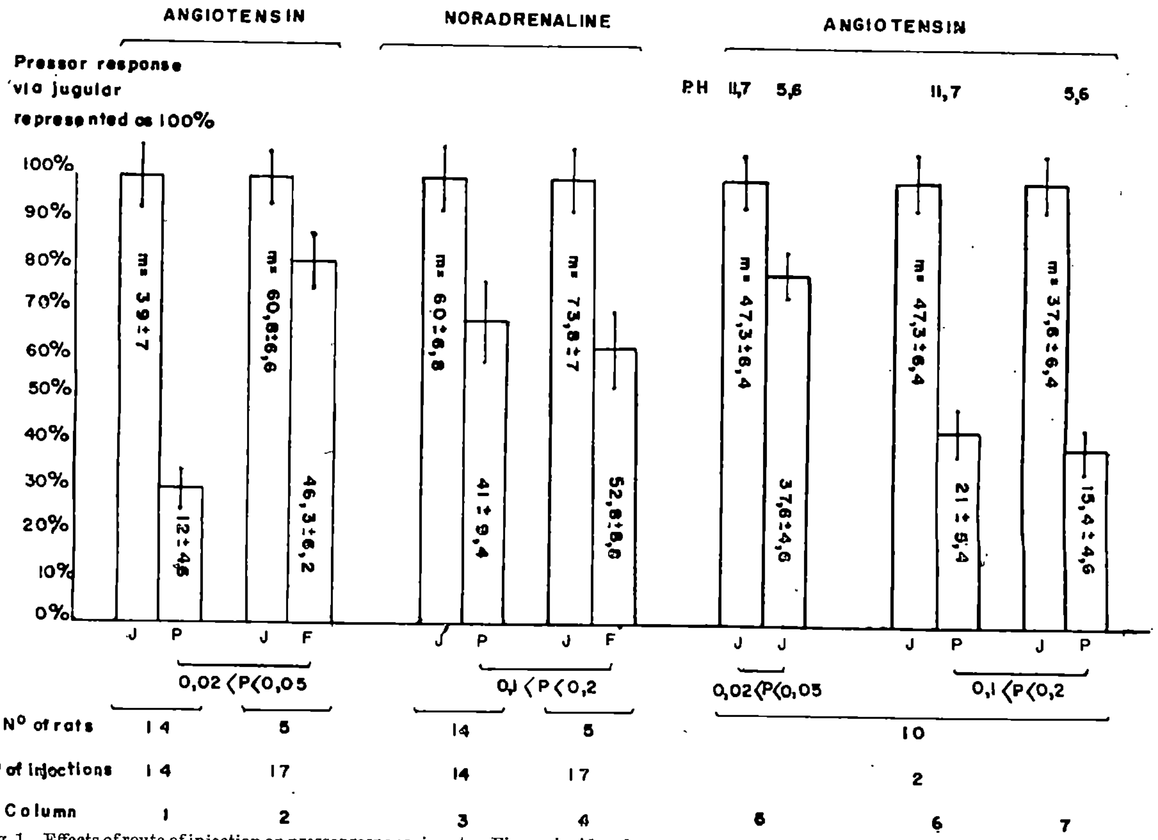

Fig. 1. Effects of route of injection on pressor response in rats. Figures inside columns are average response (mm mercury and standard deviation). *J*, jugular vein; *P*, portal vein; *F*, femoral artery

The pressor response of angiotensin via the portal system was reduced by 70 per cent in comparison with that injected into the jugular vein (col. 1). When the femoral artery was used, the extent of the reduction was significantly inferior, being only 24 per cent (col. 2). Cols. 3 and 4 show that the losses of response of noradrenaline going through the portal vein (32 per cent) and the femoral artery (37 per cent) were not significantly different from each other ($P < 0{\cdot}2$). The pressor activity of angiotensin alkalinized to *p*H 11·7 was increased by 21 per cent (col. 5); the degree of its inactivation by the liver circulation was almost identical to that of angiotensin at *p*H 5·6 (cols. 6 and 7).

The results indicate that angiotensin, but not noradrenaline, undergoes a significantly greater destruction in one passage through the liver circulation than through the peripheral capillaries. We ascribe this finding to liver angiotensinase, the role of which in angiotensin metabolism has been stressed by other data: (*a*) the *in vitro* degradation of angiotensin by liver tissue is well established[5]; (*b*) after administration of tritiated angiotensin to nephrectomized rats, more radioactivity is found in the liver than in other organs, in the form of metabolic fragments[6]; (*c*) a significant increase in plasma angiotensinase activity is found in patients with hepatic disorders such as cirrhosis, hepatitis, cholestasis[5,7] and toxæmia[8]. It is suggested that the liver may play a specific and important part in the metabolic inactivation of circulating angiotensin.

Although of smaller magnitude, the peripheral inactivation of angiotensin is nevertheless of significance and is in line with measurements of circulating angiotensin: when infused into the femoral artery of the isolated hind limb of a dog, very little of the hormone could be detected in the effluent[9]; when infused into the controlateral arm of normal subjects, much less angiotensin was recovered from the antecubital vein than from the humeral artery[2,4].

Like Paladini *et al.*[10], we found that alkalinization potentiates the pressor activity of angiotensin, but to a smaller degree (21 per cent) than that reported by those authors (66 per cent), probably because we used greater amounts of hormone per injection. Our attempt to find out whether this potentiation was partly due to an increased resistance to liver angiotensinase has shown that this is not the case.

ANATOMY

Oligohydramnios and Cortisone-induced Cleft Palate

It has been suggested[1] that cortisone disturbs the closure of the secondary palate of mouse embryos by interfering with the development of an intrinsic motive force within the palatal processes. The force is thought to be dependent on the accumulation in the palatal mesenchyme of substances which give positive results with histochemical reactions for acid mucopolysaccharides. The marked variation in the incidence of cleft palate induced in different strains of mice by similar doses of cortisone has been attributed to differences in the rate at which the intrinsic force develops[2]. Subsequent workers[3,4] have been unable to detect histochemical differences between palatal tissues of control and cortisone-treated embryos. Although cortisone diminishes the incorporation of ^{35}S-labelled sulphate in the tissues of treated embryos, it has proved impossible to distinguish between autoradiographs of palatal tissue from strains with a high and those with a low incidence of cortisone-induced cleft palate[4]. At the time of palatal closure, there is a marked similarity between the distribution of acid mucopolysaccharides in the palatal mesenchyme of mouse and rat embryos, but cleft palate has not been observed in the progeny of cortisone-treated rats[3].

The purpose of this communication is to report that cortisone reduces the volume of amniotic fluid surrounding mouse and rat embryos during the period of palatal closure, and to offer an explanation for interstrain and interspecies variation in the incidence of cleft formation which is based on morphological criteria.

Pregnant mice of the inbred strains *A/Gr*, *C57BL/Cbi* and *CBA/Cbi* were treated with 2·5 mg of cortisone from the 11th to the 14th days of pregnancy, and the embryos were recovered both before and during the period of palatal closure. These embryos exhibited an attitude of extreme flexion when compared with control embryos at similar stages of development. Indirect estimations of the weight of amniotic fluid, obtained by subtracting the weight of the embryo and placenta from that of the whole conceptus, showed a definite reduction in the weight of fluid associated with cortisone-treated embryos. Direct measurements were therefore made of the volume of fluid associated with normal and treated embryos recovered on the 14th and 15th days of pregnancy. In each strain there was a tendency for the volume of fluid surrounding treated embryos to be less than that associated with untreated embryos of similar morphological age and weight (Fig. 1). Published criteria for assessing the morphological age of mouse embryos[5] required modification to avoid the excessive rating of treated embryos due to premature 'closure' of the external auditory meatus.

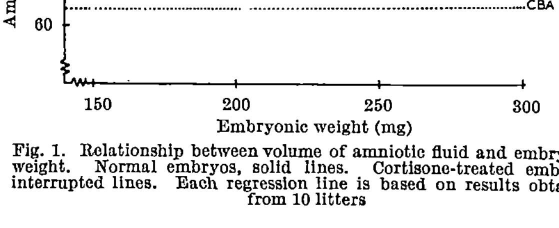

Fig. 1. Relationship between volume of amniotic fluid and embryonic weight. Normal embryos, solid lines. Cortisone-treated embryos, interrupted lines. Each regression line is based on results obtained from 10 litters

The cause of the reduction of amniotic fluid has not been established. No gross abnormalities have been observed in the heart and renal tract of treated embryos, and the possible existence of localized changes in renal glomeruli and tubules is being studied. A preliminary analysis of data obtained from the present experiments indicates that in all three strains of mice there is a tendency for the placentæ of embryos from treated litters to weigh less than those of control embryos of similar weight. Furthermore, at any given placental weight there is a tendency for placentæ from treated litters to be associated with smaller volumes of amniotic fluid.

The placentæ of treated embryos were macroscopically normal, but the membranes were invariably discoloured by a band of pigmentation which extended around the antimesometrial surface of the conceptual sac, adjacent to the decidua (Fig. 2). Much less extensive pigmentation was occasionally observed in a similar situation in the membranes of untreated embryos at earlier stages of development.

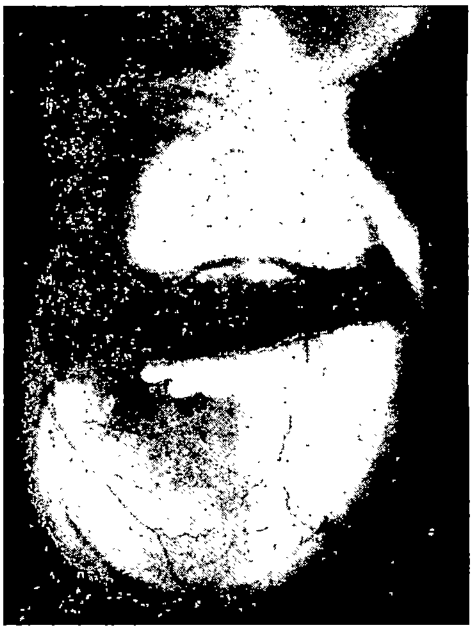

Fig. 2. Cleared preparation of part of a pregnant uterus from a cortisone-treated *A* strain mouse showing the band of pigmentation. (× 6)

The volume of amniotic fluid surrounding rat embryos during the period of palatal closure was also reduced in pregnant rats of the Chester Beatty albino and Lister Institute hooded strains which had been treated with 25 or 50 mg of cortisone from the 11th to the 15th days of gestation. There was macroscopical evidence of degeneration at the edges of the treated placentæ, but pigmentation of the membranes was seldom observed.

During morphogenesis of the secondary palate there is a change in spatial relationship between the tongue and the palatal processes. This change has been expressed quantitatively by obtaining from histological sections of embryos prepared by standardized techniques measurements of the longitudinal growth of the cranial base and Meckel's cartilage, and of the angular relationship between them. Since the cranial end of Meckel's cartilage cannot be identified on median sagittal sections, longitudinal growth of the lower jaw has been arbitrarily defined as the distance between the anterior extremity of Meckel's cartilage and the caudal end of the posterior cranial base (Fig. 3).

At the commencement of palatal closure in the rat embryos, the cranial base is flexed in the region of the craniopharyngeal canal. The point of flexion serves to

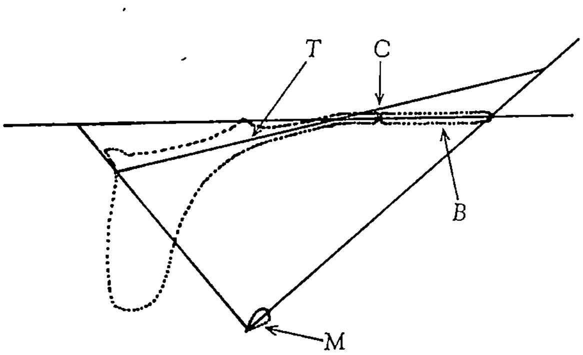

Fig. 3. Diagram illustrating portions of the chondocranium seen in median sagittal sections. Anterior extremity of Meckel's cartilage (*M*); craniopharyngeal canal (*C*); angle *T* decreases as the anterior cranial base extends; angle *B* is reduced in cortisone-treated embryos

divide the base into anterior and posterior portions. As palatal closure progresses, there is a gradual reduction in the angulation of the cranial base, and when fusion of the processes is complete, the long axes of the two portions of the base form a straight line. The amount of flexion in the cranial bases of *C57BL* and *CBA* mouse embryos at the onset of palatal closure is less than that observed in the rat embryos, but considerably greater than the amount present in embryos of the *A* strain in which the cranial base is almost straight before closure commences. There is also a definite tendency in the *A* strain embryos for the long axes of the posterior cranial base and Meckel's cartilage to be closer together. It is uncertain whether the differences noted in the *A* strain are entirely due to the greater morphological maturity of these embryos, for at the time of palatal closure there is a considerable degree of uniformity between the length of the cranial base and Meckel's cartilage in the three strains of mice.

In mouse embryos from cortisone-treated litters there is a tendency for the angle formed between the long axes of the posterior cranial base and lower jaw to be smaller than normal. The dorsum of the tongue is closer to the roof of the mouth and extension of the anterior cranial base occurs more rapidly than in untreated embryos. Extension (that is, reduction of the angle *T* in Fig. 3) is particularly rapid in treated *CBA* embryos which have the greatest reduction of amniotic fluid. The incidence of cortisone-induced cleft palate in the *CBA* and *C57BL* strains is reported to be 20–25 per cent and 17–18 per cent respectively, but in the *A* strain it approaches 100 per cent. This difference cannot be attributed to a greater reduction of amniotic fluid in the *A* strain, but it is suggested that it can be explained if the reduction of amniotic fluid is considered in conjunction with the configuration of the cranial base at the commencement of palatal closure.

The possession of a flexed cranial base may provide an embryo with a greater available range of movement in the anterior part of the head which could assist in overcoming minor degrees of malrelationship between the tongue and the palatal processes. Rat embryos possess a considerable range, and in spite of a reduction in the volume of amniotic fluid, their palatal development is not disturbed by cortisone. The range is less in *C57BL* and *CBA* embryos, but the majority appear to adjust themselves to the effects of cortisone by the rapid extension of the anterior cranial base. Embryos of the *A* strain have virtually no available range of movement because the cranial base tends to be almost fully extended before palatal closure commences. In addition this strain possesses less space between the cranial base and lower jaw. It is possible that they respond to reduction of this space by a more rapid extension of the anterior cranial base, but in this strain the available range of movement is insufficient to allow the anterior thirds of the palatal processes to clear the dorsum of the tongue before they are immobilized by extension of ossification from the maxilla.

In this explanation of the interstrain and interspecies variations in the incidence of cortisone-induced cleft palate, no reference has been made to the presumed effect of cortisone on the mesenchyme of the palatal processes. It is probable that cortisone influences the maturation of embryonic connective tissue; but in view of the morphological changes noted here, it seems unlikely that palatal closure is wholly dependent on the existence of an intrinsic force within the palatal processes.

The demonstration of a reduction in the volume of amniotic fluid provides a direct link between the palatal clefts produced by cortisone and those following the withdrawal of amniotic fluid. Since the incidence of cortisone-induced cleft palate can be influenced by genetic factors, embryos from crosses between *A* and *C57BL* mice may help to demonstrate the extent to which oligohydramnios is a contributing factor to the ætiology of this malformation.

HÆMATOLOGY

Fibrinolysins from Fibrin Clots

THREE fibrinolytic agents have been encountered in fibrin clots. The first was described as lytic factor in an earlier communication[1]. It was extracted with borate from trypsin-digested clots. It has since been found that extraction can be carried out successfully with 0·9 per cent sodium chloride and other salt solutions. Active preparations contained a 17-ketogenic steroid and were inactivated by β-glucuronidase and by heating at 56° C for 30 min. The inhibitory effect of potent lytic factor on the clotting of fibrinogen by thrombin or aqueous clot extract[1] was very marked. An amount of 0·0004 ml. prevented fibrin formation, while with 0·0002 ml. only a partial clot was produced. With recalcified oxalated plasma different reactions were observed. One-hundredth ml. of the same preparation induced formation of a complete clot in 30–35 sec; with 0·05–0·08 ml. partial clots formed in the same time interval, while 0·15 ml. prevented clotting entirely. The lytic activity of the factor was strongly inhibited by serum, even after the serum had been treated with 0·2 N sodium hydroxide to destroy glucuronides and then neutralized with hydrochloric acid.

The second fibrinolysin was obtained from retracted fibrin clots made from 0·5 ml. portions of oxalated human plasma and kept in one-tenth volume of 0·9 per cent sodium chloride at room temperature. Such clots would dissolve in 1–5 days. The lysin titre was determined as described previously[2]. In most cases the unit was 0·05 ml. of clot supernatant. Like lytic factor, this fibrinolysin was inactivated by β-glucuronidase, but, unlike the former, it was relatively resistant to heating. Exposure to 56° C for 30 min scarcely affected it; 90 per cent of its activity was destroyed at 65° C in 10 min. Serum inhibited lysin activity but would no more do so after treatment with alkali. As the result of the action of this fibrinolysin a factor accelerating plasma recalcification was liberated, as reported previously[3], but in most preparations a clotting factor, acting directly on fibrinogen, was also found to be present. Both seemed to be identical with factors from aqueous clot extracts[1,3,4]. An apparent difference in heat stability could be explained by the far higher concentration of active material in aqueous than in saline extracts.

The third fibrinolysin was encountered in aqueous clot extracts, the supernatants of clots digested in distilled water at 5° C. At this temperature scarcely any clot decomposition would take place in saline. It was inactivated by heating at 56° C for 30 min, but not by β-glucuronidase, and was inhibited by untreated, but not by alkali-treated, serum. Potent clotting and accelerating factors were present in clot supernatants. As little as 0·0001 ml. would coagulate 0·1 ml. of recalcified oxalated plasma in 25 sec. The supernatants were greenish-yellow, resembling in appearance the substrate from which a fibrinolytic metabolite was produced by a strain of *Streptococcus faecalis*[2]. Most of the pigment was able to pass through 'Cellophane' membranes, but a fraction was non-dialysable like the bacterial metabolite, and fibrinolytic activity was associated with it. When the bacteria were allowed to act on the dialysate in the presence of gluconate, as described previously[2], fibrinolysin was produced and more pigment became non-dialysable.

It seemed, then, reasonable to assume that the pigment was also present in the culture medium, brain heart infusion, in which the bacteria had been grown, but because of the many substances making up the medium isolation of this compound was not feasible. However, some of its properties could be determined by subjecting the medium to certain procedures before the addition of bacteria and gluconate for fibrinolysin generation. Boiling or drying at 37° C did not affect it. It was partially soluble in methyl alcohol and 95 per cent ethyl alcohol, but not in acetone, chloroform, or ether. It was irreversibly destroyed by exposure to 1 N hydrochloric acid or 1 N sodium hydroxide. The chemically purer clot extract dialysates displayed the same properties except for light absorption. Both the dialysate and the culture medium showed maximum absorption at 275 mμ, but the former only had a peak at 395–400 mμ. This did not change even after boiling for 20 min, but when the dialysate was dried at 37° C, its colour became yellowish-brown and with it its spectrum identical with that of the culture medium. This did not make it unsuitable as a substrate for *S. faecalis* in fibrinolysin formation. In fact, active fibrinolytic solutions, whether obtained directly from decomposed clots following dialysis or produced by bacteria, never displayed a maximum at 400 mμ.

An attempt was made to identify the pigment. The reported anticoagulant action of bilirubin glucuronide[5] served to direct attention to the bile pigments. Yet none of the usual bile pigment reactions gave positive results. The recorded absorption spectra fitted those of dipyrrol rather than tetrapyrrol compounds. It was then noted that clots formed from the plasma of patients with myocardial infarctions decomposed more quickly and yielded more pigment. This could well be ascribed to release of pigment from heart muscle dying due to circulatory failure and would explain the presence of the same pigment in brain heart infusion medium. A pigment fluorescing green spontaneously was reported to be excreted in the fæces in conditions associated with rapid atrophy of muscle tissue and was named myobilin[6]. Fluorescence was attributed to a pigment-protein complex. From it a brown pigment, mesobilifuscin, was isolated and later identified as a dioxydipyrrylmethene. Stich[7] described various types of mesobilifuscins characterized by differential solubility in water and a number of organic solvents and tried to relate this to polymerization or association of the basic molecules. According to its spectrum, the yellowish-brown pigment mentioned above could well be a mesobilifuscin, while the greenish-yellow pigment resembles in its light absorption a monooxydipyrrylmethene, such as neoxanthobilirubic acid[8]. It is worth noting that propentdyopent, an oxidation product of both dipyrrylmethenes, appears in measurable quantities in the urine of patients following cardiac failure[9].

A new avenue in heart patient therapy may be opened if association of a larger amount of the circulating water-soluble pigment with gluconate could be induced in the body. The beneficial effects of several types of jaundice on arthritic conditions[10] might be related to the same compound. According to recent investigations[11,12], dipyrrylmethene pigments are not primarily breakdown products of hæmoglobin but are involved in its synthesis. In hæmolytic anæmias accompanied by increased erythropoiesis there is an increase of such pigments, whereas in hyporegenerative anæmias and rheumatoid disease their concentration is reduced.

This work was supported in part by a grant from the Kansas Heart Association.

Uptake of γ-Globulin and Complement by Red Cells exposed to Serum at Low Ionic Strength

AT low ionic strength the rate of association of certain antibodies with their corresponding antigens is increased (for review see ref. 1) and the detection of human blood group antibodies may be facilitated[2,3]. In the course of testing sera which had been 'de-ionized' either by passage through 'Sephadex *G*-50' columns or by dialysis against a sucrose–saline solution of ionic strength 0·025, it was observed that the sera were giving 'false positive' reactions; that is to say, if red cells were incubated with their own 'de-ionized' serum at $I = 0{\cdot}025$, then washed and mixed with anti-human globulin serum, agglutination occurred. The red cells were only very weakly agglutinated by specific anti-7*S* γ-globulin sera but were strongly agglutinated by anti-β_{1E}-globulin serum and less strongly by anti-β_{1C}-globulin serum; thus the complement components C'_4 and C'_{3a} were both present on the red cells[4]. Positive results were also obtained with an immunoconglutinin serum ('auto-stimulation' type[5]). As expected, the addition of EDTA to the serum before incubation with red cells prevented the uptake of complement.

If red cells and serum were incubated together at low-ionic strength by simply diluting the serum with 10 to 40 volumes of low-ionic-strength medium, similar results were obtained although the reaction of the cells with anti-β_{1C} was now distinctly weaker.

The uptake of complement was found to be maximal at ionic strengths up to about 0·03; at about 0·035 less complement was taken up and none at all was taken up above an ionic strength of 0·085.

In these experiments the required amount of sodium chloride was dissolved in a solution of 6·0 per cent sucrose (0·175 M) to maintain osmolarity; it was found that similar results were obtained if glycine (0·32 M) was substituted for sucrose, although the uptake of complement was slightly less. The sucrose–saline solution was normally unbuffered and had a pH of approximately 5·0; buffering to approximately 7·0 with phosphate (0·003 M) or barbiturate (0·05 M) resulted in slightly less uptake of complement.

It was found that incubation of red cells and serum at low-ionic strength (I = 0·025) for even 1 min was enough to give detectable uptake of complement components but that the reactions increased in intensity with longer incubation periods and were maximal after about 10 min.

As Table 1 shows, red cells incubated with serum dialysed against low-ionic-strength medium reacted weakly with anti-$7S$ γ-globulin, and red cells incubated with $7S$ γ-globulin alone, at low ionic strength, reacted slightly more strongly. The following two experiments made it clear that the γ-globulin was required for the uptake of complement.

First, normal serum was fractionated on DEAE-cellulose. Two fractions were obtained; the first by elution with 0·02 M phosphate buffer pH 8·0 and the second by elution with 0·2 M phosphate buffer pH 8·0. Red cells washed in low-ionic-strength medium were incubated with the fractions separately and in combination, in each case diluted in low-ionic-strength medium (I = 0·025). Red cells exposed to the 0·02 M fraction (containing only $7S$ γ-globulin) as expected gave a negative reaction with anti-β_{1E}- and anti-β_{1C}-globulin sera; red cells exposed to the 0·2 M fraction (containing complement but very little $7S$ γ-globulin) gave weak reactions with the same antiglobulin sera but red cells exposed to a mixture of the two fractions gave strong positive reactions with anti-β_{1E}- and anti-β_{1C}-globulin sera (Table 1).

Table 1. Tests with anti-$7S$ γ- and anti-β_{1E}-globulin sera of red cells exposed at low ionic strength to: normal fresh serum, EDTA-treated serum, purified $7S$ γ-globulin, fractions of normal serum eluted from DEAE-cellulose and serum from a patient with hypogammaglobulinæmia, with and without added γ-globulin

Cells exposed to:	Reactions with antiglobulin sera Anti-$7S$ γ	Anti-β_{1E}*
Normal serum	(+)	+ + +
EDTA-treated serum	(+)	–
$7S$ γ-globulin alone (1%)	+	–
DEAE fractions†		
0·02 M	(+)	–
0·2 M	–	+
0·02 + 0·2 M	(+)	+ + +
Hypogammaglobulinæmic serum		
Alone	–	+
+ $7S$ γ	(+)	+ + +

* Similar but slightly weaker reactions were obtained with an anti-β_{1C}-globulin serum and with an immuno-conglutinin serum.

† The 0·02 M fraction contained only $7S$ γ-globulin; the 0·2 M fractio contained all other serum proteins with less than 10 per cent of the $7S$ γ-globulin present in the original serum.

The second experiment consisted in testing serum from a patient with hypogammaglobulinæmia (γ-globulin concentration about 30 per cent of normal). The patient's red cells were washed in saline and mixed with the patient's serum with and without the addition of purified $7S$ γ-globulin. The mixtures were then diluted with an excess of sucrose-saline (approximately 60 vol. of sucrose–saline to one of serum) and incubated at 37° C for 15 min; the red cells were then washed and tested with the antiglobulin sera. Red cells which had been mixed with the patient's serum alone gave only weak positive reactions but the addition of γ-globulin to the serum to bring the concentration to normal gave reactions which were as strong as those given by whole normal serum.

Tests were also made to see whether red cells which had taken up γ-globulin alone at low ionic strength would later bind complement. Red cells were incubated with purified γ-globulin at low ionic stength; after being washed in normal saline they reacted with anti-$7S$ γ-globulin but not with anti-β_{1E}-globulin (Table 1); they were now incubated at 37° for 15 min with an excess of fresh normal serum (at normal ionic strength) and were then washed and tested with anti-β_{1E}- and anti-β_{1C}-globulin sera; weak agglutination was observed, showing that a little complement had been bound.

It may be concluded that, for the uptake of substantial amounts of complement, red cells must be exposed to γ-globulin and complement together at low ionic strength.

Rapp and Borsos[6] have recently published observations of a rather similar nature. They observed that when sheep red cells were mixed with guinea pig complement, in a low-ionic-strength medium, lysis occurred. They obtained evidence of an 'auto-sensitizer' on sheep red cells which could be dissociated by washing the red cells in saline. However, even after the red cells had been washed they could still be lysed at low ionic strength if sufficient complement was supplied. One of the possibilities considered was that guinea pig serum, even after absorption with sheep cells, might contain a 'sensitizer' which activated complement at low ionic strength. The observations recorded here suggest that the 'sensitizer' in these experiments may have been normal guinea pig γ-globulin.

In our experiments only slight hæmolysis (5–10 per cent) was observed after incubation of red cells and serum at low ionic strength, presumably due to the relative resistance of human red cells to immune hæmolysis.

The fact that complement is readily taken up by red cells from fresh serum at low ionic strength can be turned to advantage to provide 'complement-coated' red cells as controls in tests with antiglobulin sera. Thus red cells which will react strongly with anti-β_{1E}-globulin and less strongly with anti-β_{1C}-globulin and only very weakly indeed with anti-$7S$ γ-globulin can be prepared by simply mixing one drop of whole fresh blood with 2 ml. of a solution containing 6 per cent sucrose and 0·15 per cent sodium chloride and incubating at 37° C for 15 min. After being washed twice, the cells are ready for testing.

RADIOBIOLOGY

High Resistance of Mongolian Gerbils to Irradiation

IT is known that the LD_{50} of X- and γ-irradiation for mammals ranges between 300 and 800 r. (refs. 1 and 2). While maintaining a colony of mongolian gerbils (*Meriones unguiculatus*) in this laboratory, their high resistance to radiocobalt irradiation was observed in a preliminary investigation and the results are reported here.

The dosage of irradiation was monitored at each exposure with a Victoreen Radocon. Ten animals (5 males and 5 females) of a group were selected at random for various dose-levels and their ages varied from 4 months to 1 year except for Group V, in which some young and some older animals of approximately 18 months were included. They were maintained in pairs and fed as previously reported[3]. The body-weight of the animals was recorded daily throughout the experiment. Blood samples for red and white blood cell counts were obtained by clipping the tail without anæsthesia. In the animals where a testis or ovary was removed at various times after irradiation, the anæsthetic 'Nembutal' was injected subcutaneously at a dosage of 6 mg/100 g body-weight. The gonads were fixed, sectioned and stained with hæmatoxylin and eosin.

Table 1. MORTALITY OF MONGOLIAN GERBILS FOLLOWING RADIOCOBALT IRRADIATION

Group	Irrad.	Dose (r.)	Interval between exposures (days)	No. of animals irrad.	Death		Remarks
					No.	Days after irrad.	
I (6 unilaterally castrated)	1st	1,000	64	10	2	33, 35	1 died 1 day after castration 1 died 3 days after ovariectomy
	2nd	1,000	41	8	1	16	Died 35 days after ovariectomy
	3rd	1,000	30	7	1	18	Died 62 days after ovariectomy
	4th	1,500		6	6	7, 7, 8, 9, 14, 26	1 died 64 days after castration 1 died 131 days after castration
II (5 unilaterally castrated)	1st	1,000	78	10	2	12, 19	1 died 1 day after ovariectomy 1 died 8 days after castration
	2nd	1,000	37	8	1	13	Unoperated
	3rd	1,000	33	7	2	15, 21	1 was unoperated 1 died 9 days after ovariectomy
	4th	1,000		5	0		
V	1st	1,000	31	10	1	26	
	2nd	1,000	31	9	4	10, 12, 13, 14	
	3rd	1,000		5	5	9, 9, 10, 11, 14	
IV	1st	1,500		10	9	9–19	The survivor gained 21 g and his hair turned white
III	1st	2,000		10	10	9–12	

From Table 1 it can be seen that un-operated animals were able to withstand 1,000 r. in repeated doses except for Group V in which older animals were included and the interval between exposures was short. These factors may be attributed to their mortality. The mortality following irradiation at 1,000 r. was chiefly due to operation because, among 9 animals that died in Groups I and II, 7 were operated animals. The gerbils, however, were not able to withstand a dose of 1,500 or 2,000 r. and all except one succumbed between 9 and 19 days after the exposure. Previous irradiations did not seem to increase or decrease the resistance of the gerbil to a subsequent exposure as shown by the death of 6 animals in Group I following irradiation at 1,500 r. in spite of being irradiated at 1,000 r. 3 times before. The survivors of 5 out of 10 animals in Group II following the 4th irradiation at 1,000 r. is strong evidence of their high resistance. In the majority of cases, death occurred between 9–15 days after irradiation and death of females occurred sooner than males.

In Groups III (at 2,000 r.) and IV (at 1,500 r.) there was a constant decrease in body-weight until death. The average weight loss was 22·6 per cent with a range of 15·6–27·2 per cent (Group III) and 16·7 per cent with a range of 4·4–25·2 per cent (Group IV) of the body-weight before irradiation. In the groups irradiated at 1,000 r. there was an increase of body-weight in the unoperated animals throughout the experiment. An increase of body-weight of the only survival of Group IV was remarkable, from 117 to 138 g, and the colour of its hair changed from dark-grey to white-grey about 3 weeks after irradiation at 1,500 r.

Blood counts were made on Group II before and two days after the initial irradiation. Subsequent counts were made on animals of various groups before death. In all cases there was a significant decrease in both red and white blood cell counts after irradiation. In animals where counts were made before death a severe leucopenia was noted and a significant increase in clotting time of the blood occurred.

The ovaries displayed a complete disappearance of large and small follicles 32 days after irradiation. Some medium-sized follicles were present, but the ova were either in a degenerate state or missing in the majority of these follicles. The seminiferous tubules of the testes appeared to be normal 19 day post-irradiation but by the 32nd day spermatogenetic activity ceased and no sperm was present in the small tubules of the cauda epididymis. By the 57th day post-irradiation few tubules contained germ cells and the sperm appeared to be abnormal. Thirty-nine days following first irradiation the animals in Group I were paired in an attempt to breed them but no sign of pregnancy was observed.

On autopsy the intestines of all animals appeared hæmorrhagic and the peritoneal fat displayed petechial hæmorrhages in many instances. The pyloric region of the stomach was usually hæmorrhagic but the stomach contained food in all cases.

The mongolian gerbils do not drink water, their cholesterol metabolism differs from other animals[4] as does the lipoprotein pattern[5], their water content in the body is rather low, and their adrenal glands synthesize different corticosteroids[6]. Whether or not these and other factors are correlated to their high radio-resistance is under investigation.

Increase in the Cæsium-137 Content of Man due to Radioactive Fall-out, 1962–64

THE presence of cæsium-137 in human beings was established in the United States in 1955 (ref. 1) and measurements of the average levels in a small group of unexposed subjects have been made at this Establishment since early 1956. The results of these measurements showed that there was a slow, irregular increase in the cæsium-137 content to a maximum in the summer of 1959, after which the level declined to a lower value in April 1962 than at any time since our measurements began[2,3]. The resumption in September 1961 of large-scale atmospheric testing of high-yield nuclear weapons did not result in any detectable increase in cæsium-137 contents until after April 1962, although the presence of short-lived zirconium-95 in human beings was demonstrated prior to this[3]. In this communication we are

Table 1. AVERAGE CÆSIUM-137/POTASSIUM RATIOS AND CÆSIUM-137 CONTENTS IN A CONTROL GROUP OF SUBJECTS RESIDENT IN BERKSHIRE AND OXFORDSHIRE

Date	No. of subjects	^{137}Cs/K (pc./g)	Approximate average ^{137}Cs content (nc.)	Average radiation dose-rate (μrad/h)
April 1962	15	25	3·5	0·05
July 1962	12	35	4·9	0·07
Oct. 1962	15	50	7·0	0·10
Jan. 1963	10	54	7·6	0·11
April 1963	12	64	9·0	0·13
July 1963	11	90	12·6	0·18
Oct. 1963	13	115	16·1	0·23
Jan. 1964	13	138	19·3	0·28
April 1964	13	150	21·0	0·30

The values for the average radiation dose-rates in the final column of Table 1 were calculated with the assumptions that the cæsium-137 was uniformly distributed throughout the body, and that the average weight was 70 kg. The dose-rates refer to a point at the approximate centre of the body.

reporting the results of our measurements of cæsium-137 in human beings during April 1962–April 1964; we have used throughout the technique described previously[3], which was intended primarily for estimating the lung contents of zirconium-95/niobium-95. The results of serial measurements of the latter radionuclides will be reported elsewhere.

Table 1 summarizes our findings on cæsium-137; as explained previously[3] the geometrical arrangement of detector and subject does not lend itself to accurate calibration for cæsium-137 and potassium contents, but we have abundant evidence that the cæsium-137/potassium ratios are directly comparable with those obtained by our more usual method of total body radioactivity measurement[2]. The cæsium-137 concentration (which is the quantity of interest from the point of view of radiation dosimetry) may be obtained in pc./kg by multiplying the cæsium-137/potassium ratios by 2. The average cæsium-137 content was estimated approximately by assuming an average potassium content of 140 g.

The average values for the cæsium-137/potassium ratio are plotted as a function of time in Fig. 1, together with the previously reported[2,3] values from 1956. Also plotted are the results for subjects *R* and *C*, who have consistently shown the lowest and highest values of the ratio. The difference between the two subjects can be attributed to a combination of the facts that the biological half-life of cæsium in subject *R* is known to be about 60 days, whereas that in subject *C* is at least 140 days[4,5], and that subject *R* drinks much less milk than subject *C*. Milk is an important source of cæsium-137 in the diet, but its influence in controlling the levels in different individuals is less than we originally thought[2]. Variability in the biological half-life among the individuals is probably the biggest single factor in determining the levels[5].

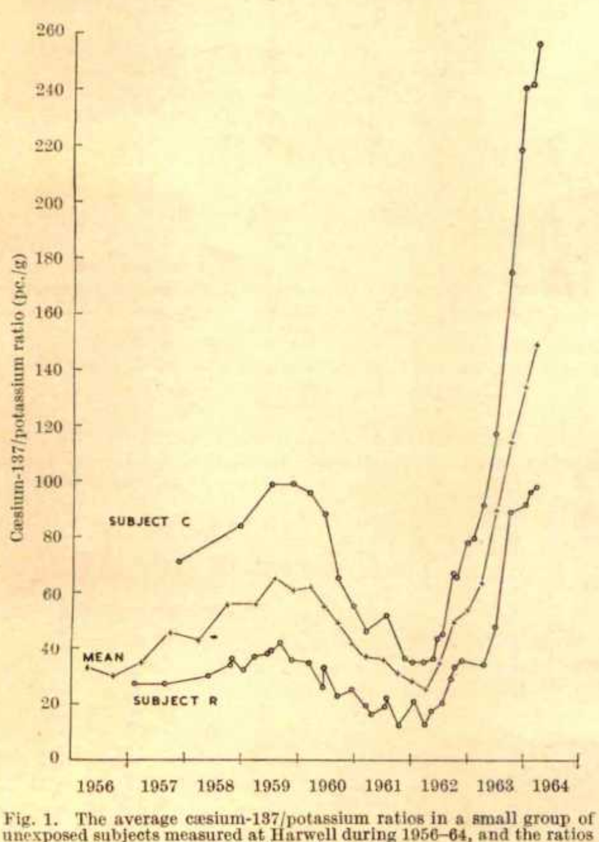

Fig. 1. The average cæsium-137/potassium ratios in a small group of unexposed subjects measured at Harwell during 1956–64, and the ratios for subjects *R* and *C*

Finally, we may note that the radiation dose-rates from the cæsium-137 are still small compared with the dose-rate from natural sources. Thus the contribution from potassium-40 amounts to 2·2 µrads/h, which is seven times the average dose-rate from the cæsium-137 in April 1964. The latter contribution amounts only to 2·6 per cent of the total dose-rate from natural sources (about 100 mrads/yr. or 11·4 µrads/h).

BIOLOGY

Splenic Regeneration

IN recent investigations in experimental carcinogenesis in the rat, following implantation of a benzopyrene tablet into the devascularized spleen[1], an incidental finding was the presence of nodules of tissue situated in the dorsal mesogastrium at six weeks after operation (Fig. 1).

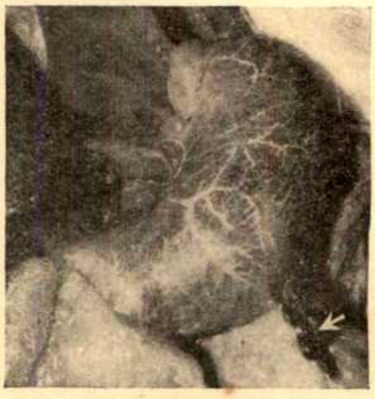

Fig. 1. Photograph of regenerating nodules in the dorsal mesogastrium indicated by the arrow (same size)

The operative procedure consisted of ligating each vascular pedicle of the organ with a double-thread ligature close to the splenic hilus. Confirmation that the blood supply was cut off was afforded by the affected splenic segments, which became a dusky black colour. In animals killed three weeks after operation no sign of the infarcted organ seen at operation could be observed.

At six weeks after operation and periods later than this, a cluster of nodules resembling splenic tissue was present in the dorsal mesogastrium. The larger nodules lay close to the greater curvature of the stomach and their size decreased in a caudal direction; septa of connective tissue were interspersed between separate nodules.

Prior injection of the arteries through the thoracic aorta and the venous system (either through the portal vein or one of its larger tributaries) showed that the main features of vascularization were: additional drainage into systemic veins, probably due to adhesions, and an arterial supply derived from nearby vessels such as the gastro-epiploic and the left spermatic arteries.

Fig. 2 illustrates the arterial supply to a cluster of nodules, injected on death with 'Micropaque' and radiographed after removal. It can be seen from Fig. 1 that the nodules are discrete and circumscribed, and that they have a rich blood supply is evidenced by the filling of their finer branches with the injection medium (Fig. 2).

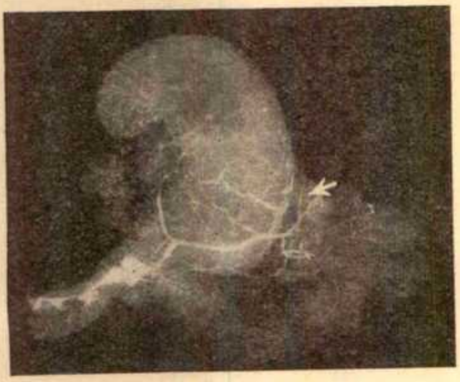

Fig. 2. Positive radiograph of the arteries to the regenerating nodules indicated by the arrow (same size)

Three possible explanations may account for the presence of these newly formed nodules. (1) They have developed *de novo* either from embryonic cell rests in the dorsal mesogastrium, or from the fully differentiated cells of this part of the mesentery. (2) They represent hypertrophy of splenic tissue which was not completely deprived of its blood supply at the time of operation. (3) They consist of tissue other than spleen, such as hæmolymphatic nodes.

The third possibility can be discarded on histological grounds, and the available evidence supports the first explanation for the following reasons: (*a*) The complete infarction of the organ, which can be seen with the naked eye, at operation. (*b*) The apparent absence of the necrotic organ in animals killed 3-4 weeks after operation. (*c*) The arrangement of the nodules, which are larger near the greater curvature of the stomach and decrease in a caudal direction. (*d*) The separation of individual nodules by connective tissue septa. The findings in (*c*) and (*d*) appear to retrace the development of the spleen in the embryo. (*e*) The arterial supply is derived from different sources other than the splenic artery, and the venous drainage occurs in part or in whole into systemic veins. (*f*) At periods later than six weeks after operation the nodules coalesce into a lobulated organ which later undergoes re-modelling to a shape comparable to that of the adult spleen in the normal rat.

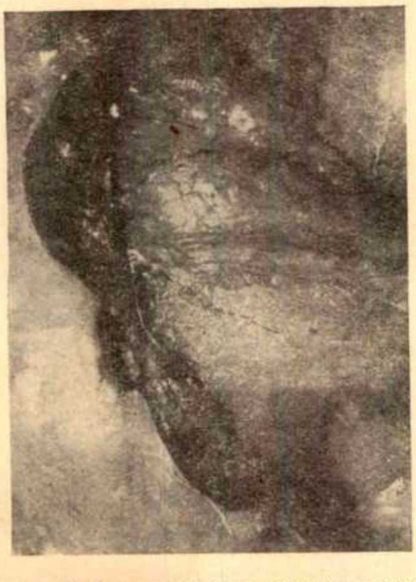

Fig. 3. Photograph of a regenerated spleen which has undergone almost complete re-modelling (× 6)

Final proof of the accuracy of this explanation, however, can only be afforded by removal of the spleen though leaving the dorsal mesogastrium intact, supported by histological confirmation of the absence or presence of mitoses in the regenerating nodules. These problems are now under investigation.

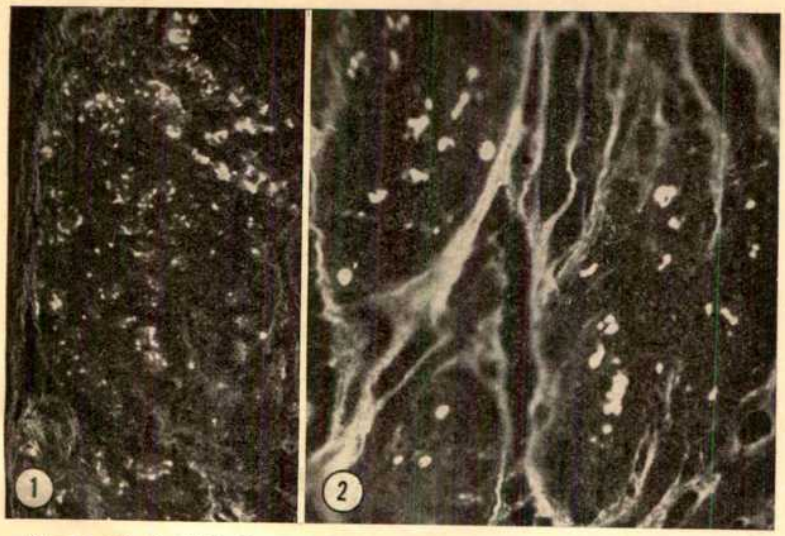
Cytochemical Demonstration of Catecholamines in the Human Carotid Body

During embryonic development, accumulation of neural components in the carotid body of human and animal subjects has been demonstrated[1]. However, efforts to demonstrate the presence of possible transmitter substances in the carotid body of adult animals have produced controversial results. While some have succeeded in showing a positive chromaffin reaction in the glomus cells of animals[2,3], others have reported negative results with the human carotid body[2,4]. There is, however, some direct chemical evidence of the presence of noradrenaline in the carotid body of the calf[5], and recently Pryse-Davies *et al.* have demonstrated in a single fluorimetric assay of a fresh human carotid body obtained at autopsy a high level of catecholamines[4].

We have recently performed a comprehensive cytochemical investigation on a number of human carotid bodies, which have been excised at operation for the treatment of bronchial asthma. The work now also includes five carotid bodies where the presence of monoamines have been histochemically examined by formaldehyde-induced fluorescence, a method originally described by Eränkö[6] and first adapted by Falck[7] to the examination of nervous tissue. The extirpated tissue was immediately frozen on a microtome tissue holder with liquid air. It was sectioned in a cryostat, in which the sections were then allowed to dry[8]. The dry sections were treated with formaldehyde gas for 1 h at 80° C, mounted in a non-fluorescent medium and examined with a fluorescence microscope.

In all the carotid bodies so far examined the formaldehyde treatment resulted in the appearance of intensely fluorescent cells in the lobules of the bodies (Fig. 1). The colour of the fluorescence was always green, never showing yellowish components. The fluorescent cells were relatively few in number (Fig. 2) and they were usually of an even size and situated separately. They were also evenly distributed among the alveoli of the lobules and did not show any clear dependence on the capillary spaces of the bodies. No fluorescing nerve fibres were visible, but the connective tissue fibres showed a non-specific fluorescence, which did not disappear after the dried sections had been exposed to moist air as did the specific fluorescence of the glomus cells.

The specificity of the cytochemical fluorescence method for monoamines is high, and the constant green colour of the omitted light can be taken as indicative of the presence of catecholamines rather than tryptamines[9]. These compounds have not been directly demonstrated before, although many indirect staining techniques have given positive indication for the presence of phenolic amines in



Figs. 1 and 2. Carotid bodies of patients suffering from bronchial asthma. Some of the glomus cells show intense green fluorescence after treatment with formaldehyde gas. The connective tissue fibres are also fluorescing, but no parenchymatous adrenergic nerves are visible (Fig. 1 × 32, Fig. 2 × 80)

the carotid body[3]. Electron microscopically membrane-bound granular bodies have been observed in some of the glomus cells; these granules could be depleted by the administration of reserpine[10].

The work recorded here shows that the human carotid body probably lacks adrenergic parenchymatous innervation. In interpreting the possible functional role of the catecholamines in the glomus cells one has, however, to remember that the carotid bodies which we have examined cannot be considered as normal because the bronchial asthma might well have altered the composition of the glomus cells from that of a normal individual.

We thank Dr. E. Vaheri, of the Department of Oto-Laryngology, University of Helsinki, for the material.

Frequency of Spontaneous Arousal from Hibernation in Bats

ALL species of mammalian hibernators 'spontaneously' raise their body temperatures to or near the normal homeothermic level at intervals during a winter's hibernation. The frequency with which such arousals occur is in part at least a species-specific characteristic ranging from an arousal every 2–7 days in hamsters[1] to maximal periods of 12–20 days in various species of the genus *Citellus*, and 20–33 days in *Glis glis*[2]. Folk[3] has reported that 4 bats (*Eptesicus fuscus*) remained without movement for 64–66 days in the dark at ambient temperatures of 4°–8° C. However, reliable information about the maximal duration of continuous hibernation (or conversely the frequency of spontaneous arousal) is available for only a few species. Reports of long periods of continuous hibernation based on daily visual observations of the postures of hibernating animals must be interpreted with great caution as there is no well-documented correlation between postural adjustment and change in body temperature in many species of hibernators.

Arousals from hibernation represent a considerable expenditure of energy and no obvious and consistent function can at present be seen to be served by them. Several theories have been advanced in an effort to explain the function of arousal from hibernation[2–4], but very little evidence is available which bears on any of them.

Results during the work recorded here were obtained by continuously recording the outputs of copper–constantan thermocouples sewn under the skin in the scapular region of hibernating *Myotis lucifugus*. Animals were maintained individually in 1-pint glass jars with 0·25 in. of water on the bottom and wire screening around the inside of the jar from which they could hang. These jars were placed in constant darkness, well insulated from noise and vibration, in a constant-temperature room which was held between 3° and 5° C. The experiments reported here were all performed during January–June. Four animals were used in 1960, 9 in 1961, and 11 in 1962. Of these 24 animals, 11 either chewed through their leads, aroused only once before dying, or otherwise produced unusable records. Results from the remaining 13 animals are considered here.

Temperatures of individual bats were monitored continuously for periods ranging from 27 to 142 days, with 79 as the mean number of days of continuous recording for the group of 13 animals. In all, 69 arousals were recorded from the 13 animals during a period of 1,023 'bat hibernation days'. Under the foregoing conditions, the duration of individual arousals was quite short (an average of 3 h 10 min during which the body temperature was more than 1° C above the ambient temperature). Thus, of the 1,023 'bat hibernation days', there were about 1,014 days of actual hibernation and 9 days of arousal.

Fig. 1 is a histogram showing the distribution of the intervals between arousals of all 13 bats. Thus, the abscissa represents the number of days of continuous hibernation with less than 1° C difference between the animal's body temperature and the environment, and the ordinate represents the number of such intervals in the entire group of animals. The short 1–5 day intervals form by far the largest group (27) and it is of some interest to note that 7 of these occurred during the 10 days immediately following the beginning of experiments, 14 occurred during the 10 days immediately preceding death, and the remaining 6 all come from one animal. The most interesting feature of the data, however, is the fact that bats are capable of very long periods of continuous hibernation, uninterrupted by arousal or in fact by any significant deviation of body temperature from ambient temperature. The two intervals of more than 80 days of continuous hibernation are from two animals, one in 1960 (which lived a total of 133 days in the experimental chamber) and one in 1961 (which lived 142 days). Both these animals had several arousals subsequent to that which terminated the long period of hibernation. Long periods of continuous hibernation account for more of the hibernation than is readily apparent in Fig. 1. Of the 1,023 bat hibernation days, almost half (490) occur in the 10 intervals of more than 30 days each.

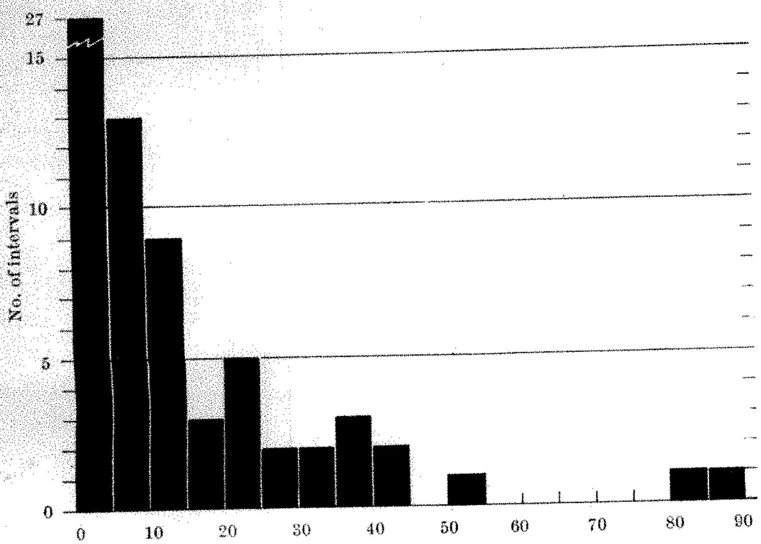

Fig. 1. The 69 intervals (periods of continuous hibernation) obtained from 13 bats have been grouped according to their durations as indicated on the abscissa. The ordinate indicates the total number of intervals in each group. Note the 2 extremely long intervals (82 and 86 days) during which the bats' body temperatures did not rise more than 1° C above the ambient temperature of 3°–5° C

It seems probable from the foregoing results that bats can hibernate without arousing for much longer periods than can any other mammalian species thus far examined. If there is to be a single interpretation of the need of all mammalian hibernators to interrupt their hibernation with periodic arousals, it must account not only for the very frequent arousals of many rodent species but also for the very infrequent arousals of bats.

This investigation was supported in part by post-doctoral fellowship 49145 from the U.S. National Science Foundation; post-doctoral fellowship *GPD*-9327-*C*1 from the Division of General Medical Sciences, U.S. Public Health Service; and by the Milton Fund of Harvard University.

Regulation of Acid Invertase-levels in Sugar Cane Stalks by Auxin- and Metabolite-mediated Control Systems

IMMATURE storage parenchyma cells of sugar-cane stalks contain an acid invertase located in the vacuoles and the outer space (cell walls). The physical properties of the enzyme at both loci appear to be identical. The enzyme is readily made soluble simply by grinding the tissue. Measurements of the rate of internode elongation and total acid invertase show that these two parameters are linearly correlated. This particular acid invertase is absent from the mature storage tissue of sugar cane, but persists in the mature tissue of two closely related species which do not store sucrose in high concentrations. However, in mature tissue of sugar cane other invertases occur but not in the vacuole[1-3].

To explain the correlation between internode elongation and acid invertase-level, we have postulated that the outer space and vacuolar acid invertase of young, rapidly expanding cells co-operate to maintain a constant high level of hexose available in the cytoplasm. The regulatory role of this enzyme depends largely on the fact that sucrose must be hydrolysed prior to entry into metabolic pathways in the storage parenchyma cells. The outer space enzyme hydrolyses sucrose originating from the conducting tissue. The vacuolar enzyme enables sucrose in storage to become available for use in metabolic processes when the supply from photosynthesis is inadequate. The level of the vacuolar enzyme may change rapidly in the course of a few hours. We have no evidence for similar rapid changes for the outer space enzyme, although the amount present varies considerably in different batches of tissue.

The postulate outlined here assumes precise regulation of the activity of the vacuolar acid invertase. A search conducted for control systems revealed two different classes of regulatory substances which affected enzyme levels in tissue slices. One class includes indolyl-3-acetic acid (IAA) and synthetic auxins. Low concentrations of IAA (10^{-5}–10^{-7} M) increased the invertase-level when incubated with tissues over 6–10 h periods, while higher concentrations decreased the level[4]. In some batches of tissue, decreased invertase activity was observed for all levels at which auxins were applied, and was taken to indicate that the endogenous auxin-level was near optimal This latter response is similar to that reported for the invertase bound to the cell walls of carrot root and artichoke stem tubers[5].

The other class of substances included certain sugars and derivatives and were effective only at relatively high concentrations (about 10^{-2} M). Some increased the enzyme-level; others decreased it. Among this class only glucose and fructose are known to occur in sufficiently high concentrations *in vivo* to have any marked effect on the enzyme content of the tissue. Both sugars always decrease the invertase-level. However, since they are readily interconvertible following phosphorylation, and are also rapidly metabolized it was not possible to conclude that either sugar acted as such.

Investigations using radioactive glucosamine provided the evidence that glucose is an endogenous regulator of invertase-levels. Glucose and glucosamine gave identical effects at different *p*H values and over a large range of concentrations. After treatment with ^{14}C-glucosamine, the unaltered sugar plus a phosphorylated compound and *N*-acetyl glucosamine were recovered from the tissue. *N*-acetyl glucosamine is not produced from glucose. On hydrolysis, the phosphorylated compound yielded free glucosamine. Kinetic considerations lead us to exclude phosphorylated sugars as possible control substances. We, therefore, conclude that free glucosamine and free glucose act directly to lower the enzyme level.

Mechanisms by which glucose might affect acid invertase content have been considered and experiments devised to test the several possibilities. When included in assay solutions at concentrations which were effective on tissue slices glucose had no effect on the activity of the enzyme. Hence it is not a competitive or allosteric inhibitor. The possibility that low molecular weight inhibitors accumulated in the tissue following glucose treatment is unlikely as exhaustive dialysis at low temperatures made no difference to the enzyme activity of crude extracts. Control by means of changes in levels of high molecular weight inhibitors or proteolytic enzymes was virtually excluded by experiments which showed that the total enzyme activity in mixed extracts was equal to the sum of the activities of extracts taken from tissue high in invertase and from tissue which had been treated with glucose to give a very low enzyme-level. Another possible regulatory mechanism would be through *p*H control as the isolated enzyme loses activity rapidly at *p*H values lower than about 5·0. However, there was no measurable difference in the *p*H of tissues treated for 10 h in glucose or water. By a process of elimination we were left with reduction of the rate of invertase synthesis as the most plausible explanation of the glucose effect[6].

The specificity of the glucose effect was shown by the observation that large changes in acid invertase could be induced without a concomitant change in the total protein content of the tissue. Its reversibility was readily demonstrated by transferring tissues incubated in glucose and containing low invertase-levels to a glucose-free medium, whereupon a rapid increase in the enzyme-level occurred. In one experiment this amounted to an 11-fold increase in 6 h.

That enzyme synthesis is involved in the increase in invertase activity following transfer of glucose-repressed tissues to a glucose-free medium has now been shown by use of chloramphenicol (CAP), a potent inhibitor of protein synthesis. Synthesis of invertase commenced in these tissues after a 2-h lag period, but no synthesis occurred if transfer was to CAP (Fig. 1). Actinomycin *D* was also effective in preventing synthesis of acid invertase, a concentration of 5 μg/ml. being required to reduce the enzyme-level by 50 per cent compared with tissues in water. Recent evidence indicates that both CAP and actinomycin owe their effects on protein synthesis to interference with the production or utilization of messenger ribonucleic acid[7,8]. A consistent interpretation of the results shown in Fig. 1 is that the glucose effect on invertase production is by repression of synthesis of the messenger RNA which specifies the amino-acid sequence for acid invertase. If so, the system has many features in common with metabolite-controlled end-product repression of enzyme synthesis as found in micro-organisms[9].

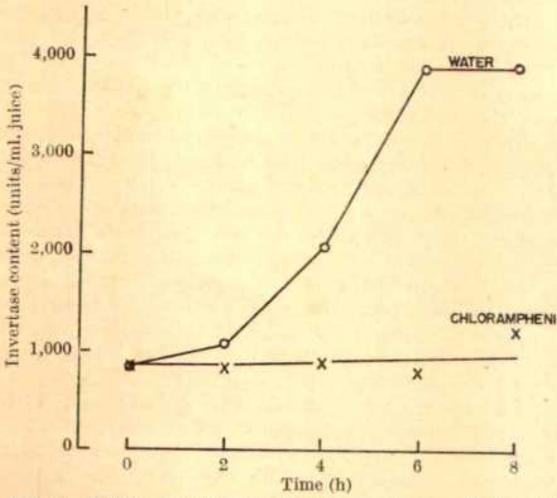

Fig. 1. Effects of chloramphenicol on invertase synthesis following release of repression by glucose. Tissues were incubated for 16 h in 0·1 M glucose, then washed under running tap-water and transferred to water or chloramphenicol solution (0·75 mg/ml.). Samples were harvested at two-hourly intervals, ground finely, the juice dialysed at 3° C, and the invertase content of the dialysate determined

From examination of the steric requirements for activity on invertase synthesis, we have learned that conversion of a sugar, active as a repressor, to its methyl glycoside virtually destroys its activity, while reduction to the polyhydric alcohol confers inducer properties on the molecule. However, the role of inducers of this type in the intact plant is uncertain as we know of no compound present at sufficiently high concentrations to be effective. It seems likely that in tissue slice investigations these inducers compete with endogenous glucose at its site of action as a repressor. Since the auxins are chemically quite different from the metabolite-type inducers and repressors and are effective at concentrations which are three to five orders of magnitude lower, we conclude that it is unlikely that two classes of regulatory substances act in the same way.

Enzyme Activation in Germinating *Petunia* Pollen

WHEN pollen and maternal tissue come into contact, the rate and sequence of enzyme activation control the growth of pollen and the nature of the compatibility reaction. Intraspecific pollination in certain plants results in an incompatibility reaction in the maternal tissue. In *Petunia*, one of the few species examined in detail, pollen growth is characterized by formation of a new protein fraction in the style and inhibition of pollen tube growth[1]. It has been postulated that this new protein forms in response to an inducer: a chemical moiety, such as a protein, which diffuses from the pollen[2].

This communication reports the effect of time and varying external osmotic environment on sucrose metabolic activity in initially germinating *Petunia* pollen. It also considers the possible relationship of enzyme protein activities to the incompatibility reaction.

More than seventy years ago Green demonstrated that *Lilium* pollen could metabolize starch *in vitro*[3]. Histochemical investigations have since shown that germinating pollen secretes many enzymes[4]. Recent investigations with *Oenothera* pollen indicate that a protein and starch digesting enzymes diffuse out of the pollen from 1 to 15 h after it is set out on an agar surface[5]. These *Oenothera* proteins reacted with antiserum prepared from whole pollen with related S genes[6]. When *Petunia* pollen is placed on a sucrose media, a number of enzymes are activated and metabolize this substrate to carbon dioxide. Assay of $^{14}CO_2$ released from carbon-14 uniformly labelled sucrose by *Petunia* pollen provides a direct means of studying the activity of these enzymes *in vitro*.

Air-dried pollen of *Petunia hybrida*, clone *W*166*K* with self-incompatibility alleles S_1S_2 from plants grown in greenhouses with supplemental lights at Nijmegen[7], was germinated in Warburg flasks with carbon-14 uniform by labelled sucrose (Radiochemical Centre, Amersham). At various time-intervals of 5–45 min the pollen was placed into the liquid media; sulphuric acid was added to terminate growth and to release all carbon dioxide. The carbon dioxide was collected in potassium hydroxide, and the amount of radioactivity in the barium carbonate precipitate of the potassium hydroxide was determined. These experiments showed that sucrose was rapidly metabolized early in the germination of the pollen (Table 1).

Concomitant growth investigations, made under the light microscope with pollen from the same sample, showed that tubes were not visible until approximately 30-min germination at 26° C in optimal concentrations of sucrose and boron, that is, 0·2 M sucrose

Table 1. $^{14}CO_2$ RECOVERED FROM *Petunia* POLLEN METABOLIZING SUCROSE-UC-^{14}C*

Pollen (mg)	Time metabolized at 26° C (minutes)	Counts per minute Total recovered	Counts per minute Increase per 5 min
7	5	124	104
7	10	254	130
7	15	640	386
7	30	1,910	424
7	45	2,960	350
0	5	23	
0	15	19	

* Each Warburg flask contained $1·9 \times 10^5$ c.p.m. sucrose-UL-^{14}C in 0·9-ml. germinating media of 0·2 M sucrose and 20 p.p.m. boron as H_3BO_3. Growth was stopped by the addition of 0·4 ml. of 4 per cent sulphuric acid from the side-arm. Centre well contained 0·2 ml. 5 M potassium hydroxide. The experiment was repeated three times with the same trends and results apparent in all experiments, although absolute counts differed.

and 20 p.p.m. boron. After half an hour at 26° C, about 25 per cent of the pollen showed tube enations; after 45 min this increased to about 60 per cent. When the $^{14}CO_2$ released at 5-min intervals in the initial 45 min of germination (Table 1) was related to tube growth, it was apparent that high levels of sucrose metabolism occurred before tubes were apparent. The rate of $^{14}CO_2$ released was relatively constant from 10 min to the termination of these studies at 45 min, except for a slight increase during intervals corresponding to times of maximum tube enation.

The effect of varying the osmotic environment on activation of this sucrose-metabolizing system was examined by substituting from 0·0 to 0·9 M mannitol for 0·2 M non-radioactive sucrose (Fig. 1). Sucrose-UL-^{14}C, 2×10^{-8} moles containing $1·9 \times 10^5$ c.p.m., was added for enzyme assay. Since mannitol has been reported to be a substrate in some plant tissues[8]; its effect on *Petunia* pollen germination first was ascertained. Visual assays showed that germination during a 3-h period at 26° C in all boron–mannitol solutions and in the controls without sucrose was less than 2 per cent.

Differences in $^{14}CO_2$ recovered from germination using mannitol from 0·0–0·33 M and from 0·66–0·9 M (Fig. 1) were not statistically significant. Differences between $^{14}CO_2$ recovered at 0·33 and 0·66 M, however, were highly significant. The increase in the external osmotic pressure apparently inhibited the release of carbon dioxide from the pollen. This observation and the fact that nearly maximum sucrose metabolizing activity—measured by release of carbon dioxide—occurs under approximately zero osmotic pressure (Fig. 1) are interesting in view of previous related investigations.

Investigations have shown that germinating pollen can incorporate free $^{14}CO_2$ into carbohydrates, amino-acids, and even proteins[9]. Inhibition of pollen growth usually occurs in sucrose solutions above 0·6 M, or with osmotic values greatly different from the pollen[10]. Thus it is unlikely that decreased levels of $^{14}CO_2$ released at increasing osmotic pressure (Fig. 1) were the result of increased activity of enzyme pathways leading to $^{14}CO_2$ incorporation. Both growth inhibition and decreased $^{14}CO_2$ release at high osmotic pressures probably result from inactivation of the enzymes involved in growth and metabolism.

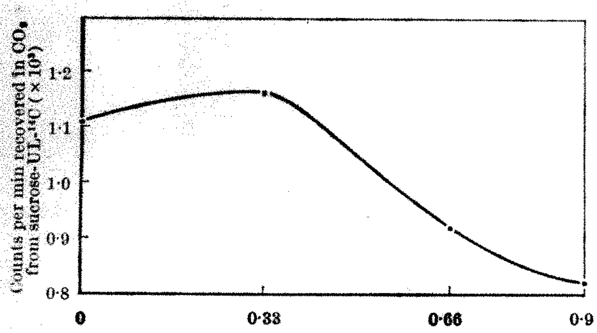

Fig. 1. Effect of osmotic pressure on $^{14}CO_2$ recovered from *Petunia hybrida* pollen during initial 15 min at 26° C. Each Warburg flask contained 7 mg pollen in 0·9 ml. solution containing mannitol at the molarity indicated plus 2×10^{-8} moles sucrose-UL-^{14}C containing $1·9 \times 10^5$ c.p.m. After being shaken 15 min at 26° C, 0·4 ml. 4 per cent sulphuric acid was added to the germinating media. Each point represents the mean of three replicate experiments

The high rates of $^{14}CO_2$ production at nearly zero osmotic pressure may be explained by one of several mechanisms. (1) At zero osmotic concentration essential enzyme proteins may be activated on the pollen surface-binding sites. (2) Pollen membranes may be 'leaky sieves' in an environment of low osmotic pressure and freely release active enzymes. (3) Uptake of water and micro-levels of radioactive sucrose may be the same in the initial 15-min period used in this study over the range 0·0 to about 0·4 molar; however, mannitol at higher concentrations would diminish water and sucrose absorption since the mannitol would dilute the water and compete with entering radioactive sucrose. (4) *In vitro* studies with enzyme preparations showed that the orientation and available charged groups decreased as concentrations of polar compounds increased[11]. Thus another hypothesis is that the rate of activation and stereo-orientation of charged groups of these pollen enzymes are normal at low molarities.

Assuming considerable amounts of non-radioactive sucrose were metabolized with the 2×10^{-8} M sucrose-UL-^{14}C leads to the conclusion that enzyme activity was lower in mannitol than in sucrose. Release of $^{14}CO_2$ from sucrose-^{14}C in mannitol was higher (Fig. 1) than from sucrose-^{14}C in sucrose (Table 1), that is, 1,150–640 c.p.m. Thus counts per min activity recovered in the all-sucrose media after 15 min was only about 60 per cent that recovered in mannitol at 0·2 M. Although dilution of radioactive sucrose was the same in 0·2 M mannitol as in 0·2 M sucrose, there was no competition for active enzyme sites in the mannitol. Non-radioactive sucrose is metabolized along with the 2×10^{-8} M sucrose-UL-^{14}C. Therefore, considering the virtual swamping with unlabelled sucrose (Table 1), enzyme activity metabolizing sucrose in mannitol is probably considerably less than that in the all-sucrose medium.

Growth of pollen tubes was not observed in 0·2 M mannitol with 2×10^{-8} M sucrose-UL-^{14}C. Such lack of growth was generally accepted as evidence that the external carbon source was not being metabolized. Although no growth occurs in mannitol, sucrose is metabolized. Lack of tube growth may only indicate that energy released from sucrose oxidation is not utilized in growth processes, or that 2×10^{-8} M of sucrose supplies too little energy or building moieties to facilitate tube growth. This result also shows that the assumed relationship between metabolism and growth may be in error in certain cell systems.

This study evaluated the ability of mannitol to support pollen tube growth, that is, germination. Hrabětová and Tupý[12] observed a slight growth of apple pollen in mannitol. Thus only by use of labelled mannitol and an analysis of the products can it be clearly demonstrated that mannitol is or is not metabolized—even though tube growth does not occur.

Detailed observations of the site of sucrose-metabolizing activity during the initial stages of pollen germination indicated that the enzymes were localized on or in the pollen, or that the enzymes were too unstable to be recovered in the surrounding solution[7]. The kind of enzyme proteins activated and diffusing from the pollen and whether they are the same as the protein inducing the incompatibility reaction must still be determined.

Antiserum prepared from whole pollen homogenates[8] or homogenates of whole styles[2] have been shown to react with diffusates from pollen with related incompatibility *S* genes. This serological test confirmed the presence in the initial pollen cells of proteins similar to those in the pollen diffusate. However, serological type reactions have never been shown to occur in stylar tissue. In fact, such simple, direct antigenic reactions are at present not thought to occur in the style[13]. Since different proteins occur after pollination of incompatible styles than after pollination of compatible styles[1], a messenger-RNA type reaction is still a valid hypothesis[2], as is the interpretation of a general protein-complexing type of reaction[14].

It is apparent from spectrophotometric investigations that other types of compounds frequently associated with proteins, such as flavanols, also diffuse into solution during the first few minutes of germination[7]. It is possible that these or related lipo-carotinoids on the pollen surface, already shown to stimulate stigma cell metabolism[15], facilitate induction of constitutive changes in the maternal tissue. The initial high stylar respiration during incompatible pollination[1] may be the result of stimulation by such components. The component that diffuses from pollen is known to be gene specific. This diffusate could exert its effect on growth by inducing, releasing, or complexing stylar proteins to activate or form a protein moiety with a different molecular weight than is normally present in compatible pollinations[14,16].

The incompatibility reaction may involve only enzyme protein, or a non-enzymatic moiety. Serological and electrophoretic methods provide a promising approach to understanding this type of incompatibility. Genotypes characterized by pollen with high initial protein and chemical activities at the surface, or in the diffusate, can be readily adapted for such investigation.

Cytoplasm Exudate from Cut Phloem

CYTOPLASM structure in sieve elements and particularly at sieve pores is of critical importance in any consideration of the translocation mechanism. The mass flow theory[1] assumes a degenerate sieve element protoplast in which vacuolar fluid fills the sieve element and is continuous through open sieve pores. A fluid flow of sucrose solution is thought to occur through sieve tubes due to an osmotic pressure gradient. Other theories propose that metabolic energy provides the motive force required to move nutrients over long distances through plants. These 'active' theories assume that the sieve elements have cytoplasmic contents similar to parenchyma cells but with exceptionally large end wall pores which are filled with cytoplasm. This interpretation is consistent with de Vries protoplasmic streaming theory[2], with Mason and Maskell's activated diffusion theory[3], with Kursanov's molecular transfer theory[4] and Spanner's electrokinetic theory[5].

My own view of cytoplasm structure in sieve elements provides another interpretation which can be linked with an active transport mechanism. In earlier papers[6,7], I put forward the proposal that transcellular strands of cytoplasm are in parallel arrangement with the long axis of the sieve elements and fill sieve pores to form a continuum in the sieve tubes. The outer membrane of the transcellular strand forms a microtubule which provides an unobstructed pathway for enclosed fluid and particulate cytoplasm. The translocation mechanism is thought to be limited to the streaming cytoplasm[6], and in this concept concentration gradients take a subsidiary role, as part of a mechanism regulating movement in and out of the translocation system. Canny[8] has put forward an alternative model in which translocation is explained as diffusive movement, initiated by concentration gradients and accelerated by transcellular streaming.

If the sieve element protoplast consists of normal amounts of physiologically active cytoplasm, as proposed by both the 'parenchyma cell' and 'transcellular strand' interpretations, it might be expected that the release of phloem pressure in cutting would result in the exudation of cytoplasm from the cut phloem. Alternatively, if sieve tube elements are degenerate only trace amounts of cytoplasm would be expected in the phloem exudate.

In this communication I wish to report the exudation of fluid endoplasm, together with two distinct kinds of cytoplasmic particles, from the cut ends of fine veins in soybean leaflets. The plants from which leaflets were taken were grown in a greenhouse under very favourable light and temperature conditions. Pieces (cm^2) were cut from the leaflets of trifoliate leaves, mounted immediately in tap water between slide and coverslip (abaxial surface uppermost), and observed with a times 40 achromatic objective. A flow of cytoplasm from the cut ends of fine veins has been recorded on 100 ft. of 16-mm ciné film. Figs. 1 and 2 are photomicrographs of the cut ends of fine veins and reveal ribbons of cytoplasm, containing particles. The smaller of the two kinds of particles are comparable in size to plant mitochondria (diam. 0·5μ) while the larger particles have the appearance of unusually small, rod-shaped chloroplasts (diam. 1·0μ, length 3·0μ). The larger particles are green and stain intensely blue-black with Lugol's iodine solution. Particles like these were previously reported[6] in the exudate from cut soybean

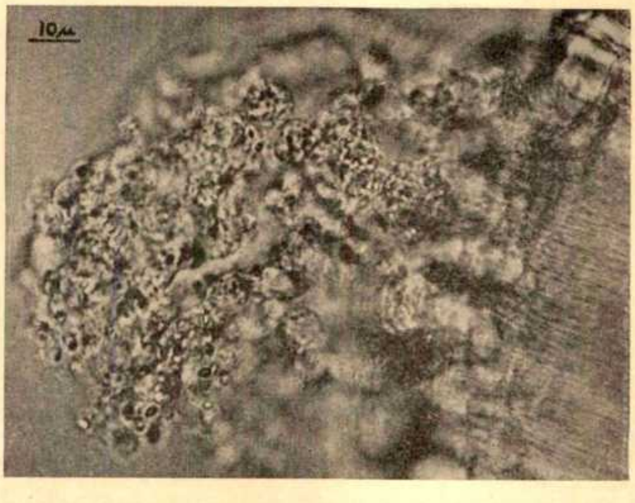

Fig. 1. Cut end of a fine vein in a cm^2 of soybean leaflet. Mitochondria-like particles and small chloroplasts are abundant in a mass of precipitated cytoplasm exuded from the cut phloem. Mounted in tap water, abaxial surface uppermost

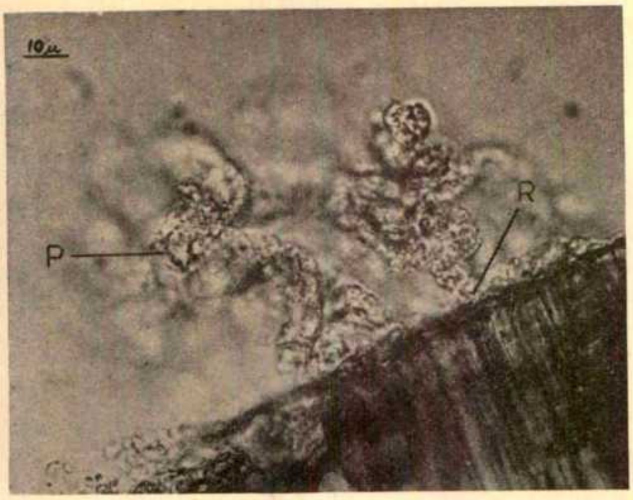

Fig. 2. A preparation similar to Fig. 1. Exuded cytoplasm has a ribbon-like form (*R*) attached to the cut ends of phloem cells. One of these ribbons shows particles (*P*) arranged in single file

stems. Some of the ribbon-shaped forms in the exuded cytoplasm can be traced back to an attachment with the cut vein (Fig. 2). In the ciné film the movement of particles can be followed in the vein and afterwards the same particles can be identified in the exudate. Measurements of vein dimensions in transverse sections were related to the planes of focus in which exuding cytoplasm was seen and, in this way, it was established that cytoplasm was exuded only by the cells of the phloem, between the sub-epidermal parenchyma and the xylem. Unfortunately, due to the interference of overlying cells, the phloem cells which gave rise to the exuded cytoplasm were not clearly defined. In most preparations, exudation continued for about 10 min, and the longest time recorded for any vein was 12 min. There was no cytoplasm exuded from cut border parenchyma cells, epidermal cells, or mesophyll cells.

The flow of cytoplasm from the cut soybean leaflet vein, and the occurrence of significant amounts of cytoplasm in soybean stem exudates[6], supports the view that sieve elements contain normal amounts of cytoplasm. Consequently, this evidence is consistent with both the 'parenchyma cell' and 'transcellular strand' interpretations of protoplast structure in sieve tube elements. Particles have already been observed moving from cell to cell in single files in mature sieve tube elements from *Primula obconica* petiole phloem[9], and in Fig. 2 it can be seen that some of the smaller particles are arranged linearly in single file, which may be a reflexion of their structural arrangement before exudation. It is therefore conceivable that fluid endoplasm and cytoplasmic particles exuded from fine veins are the contents of sieve tubes which flow from cut transcellular strands when phloem pressure is released by cutting.

I thank Prof. R. D. Preston and Dr. E. K. Woodford for their advice.

A Factor controlling Sexual Reproduction in *Phytophthora*

AN understanding of the physiology of reproduction in the fungus *Phytophthora*, one of the most important plant pathogenic genera, is hampered by there being no defined culture medium on which the sexual cycle can be completed. The fusion organs are always obtained in culture by growing it on a variety of organic media the precise compositions of which are not known; oatmeal is perhaps used the most. The only attempt to extract from such media substances which are active in promoting production of oogonia and antheridia in *Phytophthora* appears to have been by Leonian and Lilly[1]. They obtained from peas an unidentified fraction active down to 0·1 p.p.m. Zentmyer[2] reported stimulation of fusion organs in *P. cinnamomi* Rands by a non-protein extract from roots of avocado pear.

Temperate and tropical isolates which have been used are: *P. cactorum* (Leb. and Cohn) Schroet., and *P. heveae* Thompson; these reproduce sexually as single isolates. *P. cryptogea* Pethyb. and Lafferty paired with *P. cambivora* (Petri) Buis, and *P. cinnamomi*; also *P. palmivora* (Butl.) Butl. paired with *P. cinnamomi* (see Waterhouse[3]). The basic culture medium was: sucrose, 30 g; $Ca(NO_3)_2$, 0·05 g; KH_2PO_4, 0·6 g; $MgSO_4.7H_2O$, 0·3 g; L-asparagine, 2·0 g; L-tyrosine, 0·5 g; thiamine, 1 mg; agar, 15 g. in 1 l. distilled water. To 1 l. was added 1 ml. from the following solution in 100 ml.: $FeSO_4.7H_2O$, 50 mg; $ZnSO_4.7H_2O$, 50 mg; $CuSO_4.5H_2O$, 2 mg; $MnCl_2.4H_2O$, 2 mg; $NaMO_4.2H_2O$, 2 mg. The sugar and calcium were autoclaved separately from the other constituents, *p*H was 5·5 before autoclaving at 15 lb./10 min, and the two parts were mixed after cooling to 50° C. All media were used in 9-cm Petri dishes.

Vegetative growth on the basic medium was good, and comparable to that on one prepared from oatmeal; but fusion organs, as expected, formed only on oatmeal. When oatmeal was extracted with ether and the extract added to the basic medium fusion organs were formed; but they were absent on the medium prepared from oatmeal after extraction. The ether extract was then saponified[4] and only the non-saponifiable fraction was found to be active. This active material was chromatographed on a column of silicic acid (Mallinckrodt) and acid-washed 'Celite' (1 : 1 w/w) and fractions eluted with light petroleum, 1 and 25 per cent diethyl ether in light petroleum, ether and methanol. After removal of solvent by distillation the residual material was tested for biological activity. This was present only in the fraction eluted with 25 per cent ether in petrol.

This fraction, as indicated by thin-layer chromatography, contained several compounds. It was re-chromatographed on a second column of silicic acid/'Celite', and the column eluted with 5, 10, 15, 20 and 25 per cent ether in petrol. Only the 10 and 15 per cent ether fractions contained active material. The residue from these two fractions was dissolved in a minimum of hot ethanol and formed crystals on cooling; the crystals were separated and recrystallized twice. These gave a single spot on a thin-layer chromatogram, which, after spraying with 50 per cent sulphuric acid followed by heating at 105° C for 10 min, turned red.

Apparently normal oogonia and antheridia were always abundant in the basic medium to which the crystals had been added. The sterol nature of the active material, suggested by the spray reaction, was confirmed by precipitation of sterol as digitonide from the combined 10 and 15 per cent ether fractions. The sterol was regenerated[5] and shown to be active. A similar sterol was prepared from dried garden peas by digitonin treatment of the active fraction from the first chromatography.

An indication of the degree of activity of these extracts is shown in Table 1. This suggests that the extracted substances will prove active at concentrations considerably

Table 1. Formation of Fusion Organs in *Phytophthora* on a Medium of Known Composition with a Purified Extract from Oats and Peas

Days after plate inoculation		7				9				10			
Concentration active substance (p.p.m.)		10	20	40	80	10	20	40	80	10	20	40	80

lower than 10 p.p.m. The following sterols have been examined: β-sitosterol C.P., stigmasterol and cholesterol U.S.P. (Nutritional Biochemicals Corp., Ohio). These three known sterols all promote the formation of fusion organs when added at 10 p.p.m. to the basic synthetic medium. Thin-layer chromatography showed these substances to have similar R_F values, and colour reactions with sulphuric acid, as the substances from the oat and pea.

Gas-liquid chromatographic analysis of the sterol fractions (kindly performed by Dr. E. I. Mercer, Department of Agricultural Biochemistry, University College of Wales, Aberystwyth) has shown that the oat sterol mixture contains β-sitosterol and stigmasterol as the main components of the six separated. The pea sterol contains mainly β-sitosterol together with stigmasterol.

Preliminary Results of a Comparison between Tetraploid and Diploid Ryegrass

Much interest has been aroused by the introduction from Holland of bred varieties of tetraploid ryegrasses. Herbage production experiments[1] have not shown any remarkable differences in dry matter yield between these tetraploid and good diploid varieties; it was noted, however, that during the winter the tetraploids were singled out by hares for very hard grazing. The moisture content of the tetraploids is higher and in experiments at the West of Scotland Agricultural College[2] Italian tetraploid outyielded *S.*22 on a green weight basis. Dent and Aldrich[3] found that the soluble carbohydrate content of both perennial and Italian tetraploids was higher than that of comparable diploid varieties throughout the summer. In view of these findings, diploid and tetraploid varieties of both Italian and perennial ryegrass were sown in an animal production experiment in 1963; further sowings will be made in 1964. The preliminary results are presented here.

Table 1

Plot No.	Plot size (acres)	Sowing date	Seeds used (lb./acre)	Utilized herbage (D.M. 100 lb./acre) Silage	Hay	Grazing
1*a*	1·89	March 22	28 *S.*22	16·1	12·0	19·4
1*b*	1·89	March 22	30 'Tetila Tetrone'	16·5	13·1	20·4
2*a*	1·49	March 23	20 *S.*24 + 87 barley	*		23·7
2*b*	1·49	March 23	20 'Reveille' + 87 barley	*		24·9
3*a*	1·83	May 13	30 *S.*22			26·7
3*b*	1·83	May 13	30 'Tetila Tetrone'			28·0

* Not given as mainly composed of barley.

The varieties were sown in paired plots (Table 1). Fertilizer was applied either in the seed bed or as a top-dressing in July or August, the same amount being used on each of the paired plots. The plots were either cut for conservation or grazed. All grazing was done by thirteen February-born calves per plot. The yields of conserved herbage were higher from the 'Tetila Tetrone' than from *S.*22. All grass cut for silage was weighed, a sample of grass from each load being used to determine the dry matter content. The quantities of hay produced were assessed by weighing the hay bales and determining their dry matter content. The amounts of grass utilized at each grazing were estimated on the basis of a herbage intake study carried out in September and the live weight of calves. As the estimated intake was higher on the tetraploid, and average live weights were similar, the estimates of herbage utilized by grazing were higher from the tetraploid swards. The calves grazed these plots during August 13–October 28 except for a period of fourteen days. During this period the average live-weight gain of the thirteen on the diploid varieties was 121 lb. and of the thirteen on the tetraploid varieties 133 lb.

In this first year a detailed comparison was made of herbage intake of calves grazing *S.*22 Italian ryegrass and 'Tetila Tetrone' during September 15–26 on plots 1*a* and *b*. Each plot was split into three sections and each section was grazed for 5–6 days. Fæcal output was measured by dosing with chromic oxide and sampling fæces from the sward[4]. Digestibility was determined *in vitro*[5] on herbage samples grazed by an œsophageal-fistulated calf and on samples taken with hand shears. During the intake study herbage samples from both plots contained nearly 100 per cent of sown species of which 85 per cent was green leaf and sheath, 6 per cent stem and 9 per cent dead material on 'Tetila Tetrone'; the respective percentages on *S.*22 were 79, 7 and 14. Percentage ash, dry matter (D.M.) and normal acid fibre (N.A.F.) in the herbages of *S.*22 were all higher and soluble carbohydrate (S.C.) lower than in the 'Tetila Tetrone' (Table 2). The organic matter digestibility of the tetraploid was on average 3 units higher than that of *S.*22, by either sampling method. The digestibilities of samples taken *via* the fistula were higher than those of cut herbage. Furthermore, N.A.F. content of samples taken through the fistula was higher than that of cut herbage and soluble carbonate content lower. These results are undoubtedly due to the action of saliva, and so the digestibility determinations on cut herbage were used for the determination of intake[4].

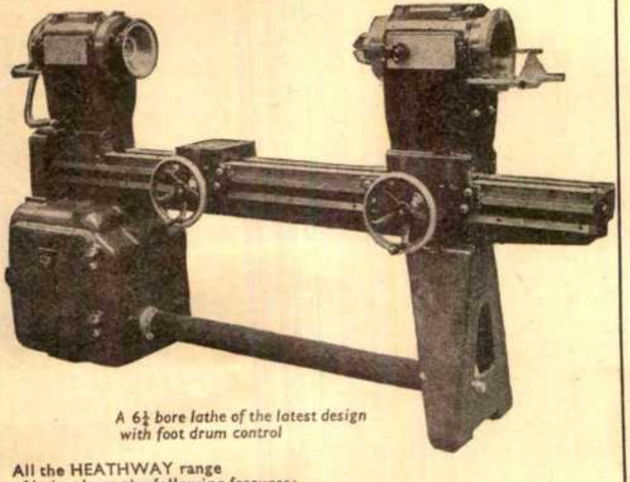
The fæces of animals grazing 'Tetila Tetrone' were darker and there was also more scouring in this group, but dry matter content of the fæces was similar (12·2 per cent *S.*22 and 12·1 per cent 'T. Tetrone'). Fæcal output was

Table 2

		% O.M. dig.	% ash	% D.M.	% N.A.F.	% S.C.	Fæcal output (lb. O.M./calf/day)	O.M. intake* (lb./calf/day)
*S.*22	Cut herbage samples	75·5	12·6	18·6	29·0	19·2	2·18 ± 0·044	8·9 ± 0·18
	Fistula samples	76·1	13·8	11·9	35·9	9·3		
'Tetila Tetrone'	Cut herbage samples	78·4	11·8	15·8	28·3	21·9	2·03 ± 0·036	9·4 ± 0·17
	Fistula samples	79·9	14·0	11·2	34·8	10·8		

* Calculated from the equation: wt. organic matter (O.M.) eaten $= \dfrac{100 \times \text{fæcal output lb. O.M.}}{100 - \text{O.M. dig. } \textit{in vitro} \text{ of cut herbage}}$

HEATHWAY
FOR GLASS WORKING LATHES



A 6¼ bore lathe of the latest design with foot drum control

All the HEATHWAY range of lathes have the following features:

- ★ **Robust Construction and lasting accuracy**
- ★ **Efficient variable speed and easily accessible controls**
- ★ **Smooth traverses essential to good glassworking**

May we send you details of our range of lathes and equipment

Synthetic Polyribonucleotides

Prepared by polymerization of nucleotides with polynucleotide phosphorylase from *Micrococcus lysodeikticus*,

These polynucleotides are of high molecular weight, suitable for both physical-chemical and biochemical studies.

In stock for immediate shipment are salts of:

Polyadenylic acid
Polyinosinic acid
Polyuridylic acid
Polycytidylic acid

Copolymers are custom synthesized with 2 to 4 different bases in any given ratio of substrates.

Custom synthesis of C^{14} and H^{3} labelled homopolymers and copolymers can also be accomplished.

COULTER
takes the strain out of sizing
AUTOMATICALLY!

No longer need you be the slave of laborious time-consuming methods of counting and sizing microscopic particles. Whatever your field of interest—industrial or biological—the Coulter Counter will register 5,000 particles a second from 0.3 micron upwards.

The Coulter Counter is an instrument of exceptional accuracy, possessing a high degree of calibration stability combined with simplicity of operation. Its use will save hours and hours of tedious work and relieve valuable skilled staff for other purposes.

Patents issued and/or pending throughout the world.

If you have particle problems or are plagued by problem particles why not write to us?

TRADE MARK

The Conference Microscope

grows on you!

The Conference follows the accepted pattern of GS 'unit design' allowing the user great latitude in choice of components and accessories so that the instrument may be tailor-built to meet individual requirements, or deal with specific programmes of microscopy.

The instrument embodies unique designs in mechanism, optics and appearance – designs which give strength, rigidity and versatility in use whilst affecting outstanding economies in expenditure.

The Conference photo-microscope employs all the basic features of the Conference as used for visual research and for micro-projection. With an intense and highly corrected light source, photographs may be taken at the fastest camera shutter speeds, and yet the illumination may be controlled and measured for exposures as long as 100 seconds on fine grain film.

GS LONDON

GILLETT & SIBERT LIMITED

BATtersea 0117

highest on *S*.22 but, with the higher digestibility of 'Tetila Tetrone', intake was estimated to be higher on the latter. The average weight of the two groups of calves was similar at this time.

The hay made from plots 1*a* and *b* was fed to one pair of dizygous twin cattle housed in individual pens during a four-month period. The hays fed to the animals were changed over at intervals. The mean intakes, lb. of organic matter per 100 lb. live weight, were 1·7 for *S*.22 and 1·8 for 'Tetila Tetrone'. The O.M. digestibility of the hays measured *in vitro* was 73·8 for *S*.22 and 76·7 for 'Tetila Tetrone'. When an animal was fed 'Tetila Tetrone' hay it appeared to gain weight at a faster rate, but with the complication of gut fill in the short periods of feeding the validity of this measurement is doubtful. The fæces of the animal fed *S*.22 always appeared to be firmer but the dry matter contents were again similar (*S*.22 13·2 per cent, 'T. Tetrone' 13·6 per cent).

All the results favour the tetraploid varieties. The differences between *S*.22 and 'Tetila Tetrone', if confirmed, could be sufficient to have a significant effect on animal performance during a grazing season.

Wax and the Water Vapour Permeability of Apple Cuticle

THE storage characteristics of apples depend on the variety. In particular some varieties have a tendency to shrivel or 'wilt' because they have lost excessive water by transpiration. The transpiration rate of an apple will clearly depend on the resistance to water vapour movement of the apple cuticle.

If an apple cuticle is separated from its adjacent tissues and is then immersed in warm ether, the ether soluble fraction, referred to here as 'wax', amounts to some 50 per cent of the total cuticular matter[1]. It has been shown that transpiration from leaf surfaces[2] and insects[3] is affected if the cuticular wax is disturbed. The question arises, therefore, as to what influence wax has on the permeability of apple cuticles.

The varieties selected for study were the relatively wilt resistant 'Granny Smith', and the relatively wilt susceptible 'Golden Delicious'. Eight disks of apple skin were carefully peeled from each of these varieties, which were of normal maturity and had been in cool store. To prevent the disks curling, they were mounted on a polythene annulus. The underlying cellular matter was removed using a gentle enzyme method[4]. Cuticular wax was removed from half the disks by soaking them for half an hour in two successive solutions of hot chloroform. The central area of each cuticle (5 cm^2) was then sealed with micro-crystalline wax over an aluminium pot containing distilled water. The pots were placed in an air stream circulating at 70 ft./min and controlled at 25° C and 50 per cent relative humidity. The rate of loss of water was determined gravimetrically. The method was so designed that it was not necessary to handle the cuticle surface.

The results thus obtained are shown in Table 1. The limits quoted are the standard error of the means.

To check the reliability of the method, the transpiration of whole apples under the same conditions was measured. The permeabilities of the apple cuticles were then calculated on the assumption that the vapour inside the apple was saturated.

Table 1. PERMEABILITIES WITH AND WITHOUT WAX

	Permeability (mg day^{-1} cm^{-2})		
	Wax intact	Wax removed (uncorrected)	Wax removed (corrected*)
Granny Smith	1·5 ± 0·2	67 ± 7	107
Golden Delicious	3·2 ± 0·4	64 ± 4	98

* It is necessary to apply a small correction for the impedance of the dead air between the water surface and the cuticle, and the stagnant air film adhering to the outer surface. To determine this impedance, a thin porous paper of negligible impedance was sealed across a pot in place of the cuticle. The measured permeability was 180 mg/day^{-1} cm^{-2}. This corresponds to an air layer of total thickness 1·8 cm. The correction is negligible for the low permeability cuticle with intact wax.

The results shown in Table 2 are believed to be in error by not more than 10 per cent. They show reasonable agreement with the more direct measurements.

Table 2. PERMEABILITIES MEASURED *in situ*

	Permeability (mg/day^{-1} cm^{-2})
Granny Smith	2·5
Golden Delicious	4·0

The difference in permeability between cuticles with and without wax is striking. For 'Granny Smith' the ratio is 1 : 70 and for 'Golden Delicious' 1 : 30.

These figures demonstrate that the cuticular wax is a prime factor determining the impedance to water vapour of an apple cuticle. The reason for the difference between the varieties is not known. It is possible that the density or geometry of the lenticles is important or it may be that the distribution or type of wax plays the dominant part. Further work aimed at resolving this point is in progress.

Promotion of Cell Division in Tissue Cultures by Gibberellic Acid

IT is well established that gibberellic acid (GA) stimulates not only cell extension but also cell division in intact plants[1,2]. It has been shown that cambial division is stimulated when GA is applied to disbudded woody shoots (including those of *Acer pseudoplatanus*)[2], but that the derivative cells do not undergo further expansion and differentiation unless indolyl-3-acetic acid is also supplied; moreover, the rate of cambial division is greatly enhanced when both hormones are applied simultaneously. Reports on the effects of GA on the growth of tissue cultures are more contradictory. Netien[3] states that GA inhibits callus tissue growth while Schroeder and Specta[4] obtained an increase in callus tissue growth in the presence of GA. Nickell *et al.*[5] investigated a large number of tissues grown in callus culture and found that GA (10 p.p.m.) in some cases caused promotion and in other cases caused inhibition of growth. These experiments were carried out on callus cultures grown on agar and in all cases the results were expressed in terms of fresh weight increase. It cannot be said from this whether GA is effecting cell division or cell enlargement, though Schroeder *et al.* suggest from anatomical observations that there was an increase in cell number in their experiments.

A series of experiments has been carried out using tissue derived from the cambium of sycamore (*Acer pseudoplatanus*), growing both on agar as a callus, and in liquid suspension culture. In both cases a modified Heller salt medium with added vitamins was used as the culture medium. No coconut milk was added to the medium.

In the case of cells grown in liquid suspension culture GA was found to promote cell division at concentrations from 15 to 50 p.p.m. but not below 15 p.p.m. (Fig. 1). At

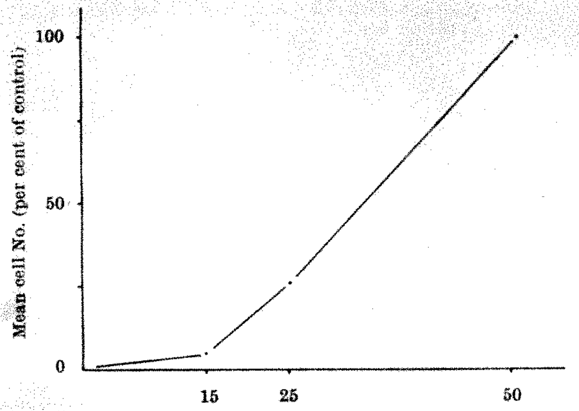

Fig. 1. Effect of increasing GA concentration on cell number. Control (no hormones) is zero

50 p.p.m. GA there was a 100 per cent increase in cell number as compared with the controls to which no hormones had been added. This stimulation of cell division was slightly enhanced by adding IAA (1·0 p.p.m.). Callus cultures grown on agar showed no increase in fresh weight when treated with 50 p.p.m. GA and in certain cases there was slight inhibition of growth as compared with the controls.

Observations on the size of the cells of the suspension cultures treated with GA show that with increase in cell number there is a corresponding decrease in mean cell size, indicating that though GA treatment is promoting cell division it is not promoting cell expansion to the same extent (Fig. 2). It is suggested that the reason for the failure to observe an increase in fresh weight in the callus cultures in response to GA treatment is due to the fact that, although cell division is promoted, there is little cell expansion and so the overall fresh weight does not increase.

It was noted in suspension cultures that there was a significant increase in cell number only at relatively high GA concentrations (about 15 p.p.m.). This indicates that the cultures may be relatively self-sufficient for gibberellins, and it has been shown previously[6] that callus cultures are capable of synthesizing gibberellins. The medium in which a suspension culture had been growing was bioassayed using a dwarf pea assay, and small amounts of gibberellins were detected. No gibberellin activity was found in medium which had not supported the growth of a cell suspension.

It has also been found that cell suspensions grown in a Heller salt medium containing 20 per cent coconut milk show increased cell division in response to GA. Again, 50 p.p.m. GA gives about 100 per cent increase in ce number as compared with the control.

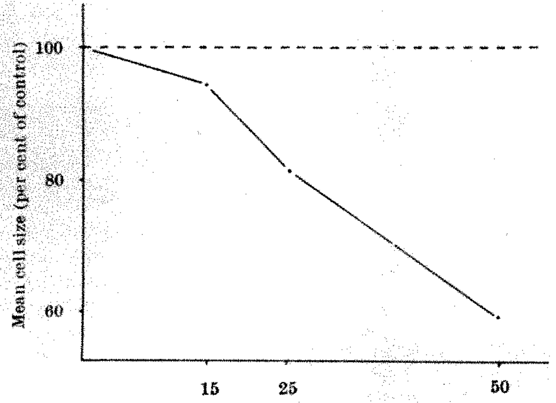

Fig. 2. Effect of increasing GA concentration on mean cell size. Control (no hormones) is 100

Thus it has been shown that GA promotes cell division of the cambium of sycamore both in the intact shoot and when the cambial cells are cultivated in liquid suspension tissue culture, suggesting that gibberellins are importan in the stimulation of normal cambial activity.

We thank Dr. D. H. Northcote, Department of Biochemistry, University of Cambridge, for providing the sycamore cambial cultures and for his assistance in the early stages of this work. This work was carried out during the tenure of a Department of Scientific and Industrial Research studentship by one of us (J. D.).

MICROBIOLOGY

Development *in vitro* of Bacterial Cross-resistance involving Penicillins, Chloramphenicol and Tetracycline

The selection of antibiotic-resistant variants of bacteria can readily be demonstrated *in vitro* by repeated transfer of the culture in the presence of the particular antibiotic in question. Resistant variants isolated in this way show cross-resistance to other antibiotics of similar chemical structure to the antibiotic in which the original organism was cultured. Cross-resistance among unrelated antibiotics has been reported on occasion[1–5] with strains of bacteria selected from *in vitro* experiments, but the phenomenon has not become well established and it is usually accepted that cross-resistance is not seen among chemically dissimilar antibiotics. We now wish to report the development of cross-resistance between certain penicillins, chloramphenicol and tetracycline, with bacteria cultured in the presence of any of these antibiotics.

The results of experiments with a strain of *Salmonella paratyphi B* (B.R.L. 1824) are shown in Table 1. This culture was sensitive to ampicillin, benzylpenicillin, chloramphenicol, streptomycin and tetracycline before repeated transfer in sub-inhibitory concentrations of these antibiotics. After resistance had developed to the particular antibiotic in which the organism was transferred, the resistant culture was tested for sensitivity to the other antibiotics. It was found that there was cross-resistance between the penicillins, chloramphenicol and tetracycline, such that the increase in resistance which developed as a result of culture in the presence of one of these antibiotics was accompanied by a lesser, but nevertheless significant, increase in resistance to the other,

Table 1. SELECTION *in vitro* OF ANTIBIOTIC-RESISTANT VARIANTS OF *Salmonella paratyphi* B (B.R.L. 1824) SHOWING CROSS-RESISTANCE INVOLVING PENICILLINS, CHLORAMPHENICOL, AND TETRACYCLINE

Antibiotic in which culture was transferred	No. of transfers	Minimum inhibitory concentration (μg/ml.)				
		Ampicillin	Benzyl-penicillin	Chloram-phenicol	Tetra-cycline	Strepto-mycin
None (parent culture)	0	1·25	12·5	5·0	1·25	12·5
Ampicillin	12	250	> 500	50	25	25
Benzylpenicillin	12	125	> 500	50	25	12·5
Chloramphenicol	10	25	125	125	50	5·0
Tetracycline	10	25	125	25	125	25
Streptomycin	4	1·25	5·0	5·0	1·25	> 500

unrelated, antibiotics. The development of this multiple resistance occurred in a gradual stepwise manner, and there was no evidence that polyresistant variants were present in the original antibiotic-sensitive cultures.

In contrast to these findings, the multiple-resistant variants described here were, in general, as sensitive to streptomycin as was the parent strain, and streptomycin-resistant variants of the original culture of *Salm. paratyphi B* (B.R.L. 1824) remained sensitive to the penicillins, chloramphenicol and tetracycline. Likewise, a culture of this organism repeatedly transferred in the presence of ampicillin showed no change in sensitivity to cycloserine, kanamycin, neomycin or polymyxin.

The development of cross-resistance involving penicillins, chloramphenicol and tetracycline was also demonstrated with a strain of *Escherichia coli*, a strain of *Klebsiella pneumoniae* and several *Salmonella* species. Cross-resistance was not seen with two strains of *Proteus mirabilis*, and one strain each of *Shigella flexneri* and *Shigella sonnei*.

It would seem, therefore, on the basis of the findings reported here, that the emergence of antibiotic-resistance *in vitro* should not be regarded as a phenomenon which is highly specific for the antibiotic in which the bacterial culture is transferred. On the contrary, it is evident that cross-resistance among dissimilar antibiotics can readily be demonstrated *in vitro* with certain bacteria, particularly species of *Salmonella*, although the clinical significance of this is as yet not known.

These results will be reported in detail elsewhere.

Role of Cobalt in Nitrogen Fixation by *Azotobacter chroococcum*

COBALT is known to accelerate nitrogen fixation by the blue-green algae, and the lowest cobalt requirement of *Nostoc muscorum* was observed to be 0·05 p.p.m.[1]. Its influence on *Azotobacter* does not seem to have been examined critically. The experiment recorded here was therefore planned to examine the effect of cobalt at different concentrations varying from 0·02 to 5·0 p.p.m. on nitrogen fixation by *Azotobacter chroococcum* in Jensen's medium[2]. The results obtained were compared with those observed with molybdenum, which was already known to be essential for *Azotobacter*. The basal medium was tested for cobalt and molybdenum by 'Nitroso-*R*-salt' method[3] and *Aspergillus niger* method respectively. While cobalt could not be detected in the medium, molybdenum of the order of 0·00028 p.p.m. was found to be present. The cobalt salt $CoCl_2{\cdot}6H_2O$ used was also tested for molybdenum by the same method as mentioned here, and it contained 0·0001 p.p.m. of molybdenum at 0·1 p.p.m. concentration of cobalt, at which nitrogen fixation was found to be enhanced.

The results indicated that cobalt at a dose as small as 0·1 p.p.m. increased the amount of nitrogen fixed. At 1·0 p.p.m. and higher concentrations, however, the response was less. Molybdenum was found to accelerate nitrogen fixation at and above a concentration of 1·0 p.p.m. examined. Higher concentration of molybdenum up to 5·0 p.p.m. examined did not result in any further increase in this value.

Table 1. EFFECT OF COBALT AND MOLYBDENUM IN NITROGEN FIXATION BY *Azotobacter chroococcum* IN JENSEN'S MEDIUM

Conc. (p.p.m.)	Nitrogen fixed in mg/g of sucrose oxidized (average of 4 replications) Molybdenum	Cobalt
0·00	6·06	6·06
0·02	6·47	6·22
0·10	6·35	9·00
1·00	13·10	8·35
2·00	13·82	8·22
3·00	13·25	8·20
4·00	13·25	7·90
5·00	13·88	7·95
S.E.	0·069	*S.E.* 0·090
C.D. at 5% level for Mo	0·21	*C.D.* at 5% level for Co 0·27

In order to find out the extent to which molybdenum as impurity in the cobalt salt would influence nitrogen fixation, another experiment was conducted with a control, 0·0001 p.p.m. of molybdenum and cobalt (0·1 p.p.m.), before and after removal of traces of molybdenum from the culture medium following the method of Nicholas[4].

Table 2. NITROGEN FIXED IN MG/G OF SUCROSE OXIDIZED (average of 4 replications)

Before removal of Mo			After removal of Mo		
Control	Mo 0·0001 p.p.m.	Co 0·1 p.p.m.	Control	Mo 0·0001 p.p.m.	Co 0·1 p.p.m.
6·74	6·9	9·66	7·21	6·83	9·73
S.E.	0·3276		*S.E.*	0·2148	
C.D. at 5% level	1·05		*C.D.* at 5% level	0·69	

From the foregoing it can be seen that enhanced nitrogen fixation observed was only due to cobalt and not to molybdenum present as impurity in traces.

Cobalt, being the centre of a complex in vitamin B_{12}, is likely to play an important part in plant and animal metabolism as vitamin B_{12} is known to have a definite role in cell synthesis.

We thank Dr. B. P. Pal, director, Indian Agricultural Research Institute, New Delhi, and Dr. R. V. Tamhane, the then head of the Division of Soil Science and Agricultural Chemistry, for their advice.

Deoxyribonuclease Activity from 'Lactic Acid Pleuropneumonia-like Organisms'

THE relationship of the micro-organisms of the pleuropneumonia group (PPLO, Mycoplasmatales) to the true bacteria is uncertain. Two general explanations have been advanced to explain the nature of this group and its relation to other micro-organisms[1]: one holds that pleuropneumonia organisms are a natural biological class; the other that PPLO are an assemblage of the stable *L* forms of various bacteria.

Previously we have emphasized the basic biochemical heterogeneity of the organisms making up the group[2] and proposed that primarily these organisms could be divided into sets consisting of fermentative and non-fermentative strains. These fermentative strains were characterized as catalase negative, nitrate negative aerobes that accumulate lactic acid. This description is highly reminiscent of certain lactic acid bacteria, particularly the *Streptococci*. I would term this set of organisms 'lactic acid pleuropneumonia-like organisms'.

Either the resemblance between this set of pleuropneumonia organisms and the lactic acid bacteria occurs because these *Mycoplasma* and the Lactobacillaceae are homologous groups that have arisen coincidentally in Nature or these PPLO are in fact stable *L* forms of certain members of the Lactobacillaceae.

To characterize further these fermentative PPLO and also aid in the selection of possible bacterial parents, a search for enzymes common to the armory of the *Streptococci* was made. DNase activity was sought preferentially because the DNases are well characterized and because of the possibility of finding and characterizing a specific cellular enzyme inhibitor. Also, in particular, a knowledge of DNase activity would be important in preparing DNA for characterization.

This communication describes deoxyribonuclease activity found in three fermentative strains[2] of PPLO: Sewage *A* (*M. laidlawii* A), California calf, and kid strain of goat arthritis PPLO. Organisms were grown at 37° C in Difco trypticase soy broth adjusted to pH 7·8–8 and (except sewage *A*) supplemented with 10 per cent horse serum. Cells were gathered at 36–48 h, washed once in 0·89 per cent saline, disrupted by three or more cycles of freezing and thawing, and taken up in *tris*–hydrochloric acid buffer (0·05 M, pH 7·5); a supernatant (15,000g, 30 min) was examined for activity. Enzyme activity in culture supernatants of sewage *A* was partially purified by ammonium sulphate fractionation.

Initially activity was assayed by the alcohol precipitation method of McCarty[3]; quantitative assays were by viscometry[4]. Enzyme activity was calculated from the slope obtained by plotting, on semi-logarithmic paper, the difference between flow-time at intervals during the reaction and the flow-time of solvent, against time. Usually five points were obtained and gave straight lines for at least 12–15 min. The activity of PPLO DNase was compared with a crystallized standard DNase I (Worthington, 1 methyl green unit per mg[5]).

The pH optimum is 7–8 in *tris*–hydrochloric acid or barbital–hydrochloric acid buffer. A divalent cation requirement is satisfied by Mg^{++} or Mn^{++} (0·0075 M) while disodium ethylenediamine tetraacetate completely blocks activation; activity is restored by addition of Mg^{++}.

Activity requires protection (provided by 0·01 per cent gelatin) and is destroyed by heating for 5 min at 60° C. Dialysed ammonium sulphate fractions are stable for at least 4 months at $-10°$ C.

The deoxyribonuclease from sewage *A* has been examined more extensively. Activity of culture supernatants is equivalent to approximately 0·3 μg of crystalline pancreatic DNase per ml. Calf thymus and salmon sperm DNA are attacked at the same rate without a lag period.

Inhibition of DNase activity with boiled cell extracts of sewage *A* and *E. coli* has been obtained, but only to a level of 30 per cent so far; yeast RNA (0·3 mg/ml.) inhibits 50 per cent of the activity. The inhibitory effect is abolished by digestion (37° C for 30 min) with RNase (50 μg/ml., heated 80° C for 10 min). Treatment of crude culture supernatants with RNase does not increase activity.

Because of the rapid loss of viscosity, the enzyme would appear to be an endonuclease, and resembles the RNA inhibitable DNases of *Streptococci* and *E. coli*.

PSYCHOLOGY

Sex Differences in Hemispheric Asymmetries of the Human Brain

THE minor and seemingly random morphologic differences between the two hemispheres stand in contras to the marked and consistent differences in their function as reflected, for example, in the specialization of the le hemisphere for speech[1]. Some evidence that unilater removals of cerebral tissue have different effects in th two sexes[2] suggests that relationships between morpholog and function might become apparent if observations o cerebral asymmetry were analysed for each sex separatel Of interest in this respect is a recent investigation b Conel of a series of eight brains from 4-year-old children no consistent feature was apparent in the difference between the hemispheres. However, if the sex of th children is taken into consideration, two noteworth differences emerge. Conel's Table IX shows that in 4 ou of the 5 female brains the amount of myelination is great in the left FA_γ-hand area than in the corresponding are on the right, while in the 3 male brains this difference i reversed. In Table X the number of exogenous fibr in layer I of areas FA_γ and PB is greater on the rig in the 4 female brains for which data are provide but greater on the left in 2 of the 3 male brains. Neith of these comparisons reaches acceptable levels of statistic significance, but the importance of, and the difficulty i obtaining, these limited data may warrant a conjectur Could these anatomical differences be related to th finding that side differences in the tactual thresholds o the thumbs of young children are not the same for th two sexes[4] ?

Some earlier research may also be used in speculatin about sex differences in cerebral asymmetry. An invest gation of variations in cerebral venous drainage sugges that the right vein of Trolard is larger than the left i girls, but not in boys[5]. Since this is often the major vei in the hemisphere opposite to that used in speech[6], it possible that the differences in venous drainage a related to the superiority of girls over boys in certai verbal skills[7] ?

These questions are not presented as being derive from relationships which have been reliably demo strated, but are posed as questions deserving systemat research. The observations indicate that the sex patients is a factor which should be heeded in investig tions of the laterality of cerebral function.

Formation of Higher Habits

ALMOST since the beginning of the systematic stud of performance experimenters had noticed the tenden for subjects to combine 'elements' into 'groups' f perceptual and motor purposes. One of the class studies in human learning is the series of experimen on morse-learning by Bryan and Harter[1], who show some sixty-five years ago that the process of learni was arrested periodically and that 'plateaux' appear in the learning curve for receiving. This they interpreted by supposing that during the plateaux subjects consolidated what they had learned previously and reorganized elements into higher order groups: from dealing with inputs letter by letter one proceeds to words, phrases and whole sentences. A similar progression was postulated for learning to send, even though no plateaux were found. Their interpretation has generally been accepted but so far as we know it has never been put to the test. We have gone a little way towards remedying this defect, and wish to communicate a first set of results.

If one could generate word vocabularies made up from the same set of letters and train subjects on one vocabulary, transfer to another vocabulary of the same size could indicate whether subjects were still dealing with letters or had learned to deal with words: if there were no decrement it would be fair to assume that subjects were still dealing with letters only; but the presence of a decrement would suggest that subjects had started to deal with the words of the first learned vocabulary and had now to relearn a new set of words. The course of the process could then be studied by varying the vocabulary sizes and moments of transfer.

Our input consisted of meaningful five-letter words made up from the letters ADEHLNORST. The words were displayed on printed lists and subjects had to copy them into a ten-finger keyboard. Time and accuracy scores were obtained and subjects were trained for ten days, the first day's training being on single letters. Two pairs of vocabularies of size 100 and 10 words respectively were made up with certain constraints and separate groups of subjects trained first on one member of a pair and afterwards transferred to the other.

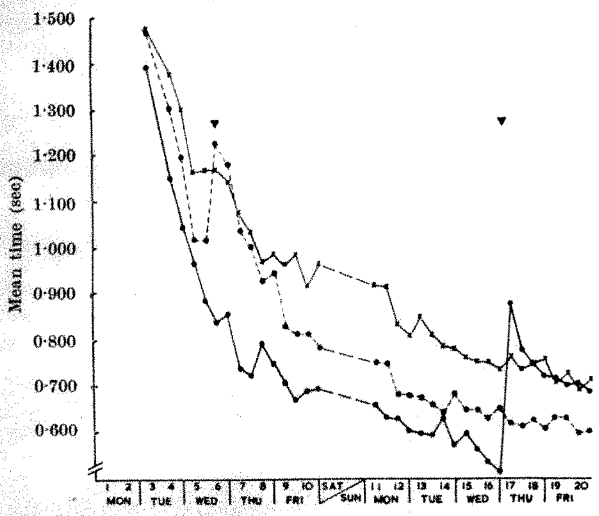

Fig. 1. Showing learning curves for three groups of subjects in terms of mean time per response for successive blocks of 5 × 50 responses. There were 6, 5 and 9 subjects in each group. Arrows mark the points of transfer from vocabulary 1 to vocabulary 2. —●— Small vocabulary late transfer; --●--, small vocabulary early transfer; ×, large vocabulary late transfer

Fig. 1 shows what happened to the mean time per response for three groups of subjects: there were two groups trained on a small vocabulary of ten words, and one which was trained on a large vocabulary of 100 words. When the subjects in the large vocabulary group were transferred to another large vocabulary after 7 days of training there was no decrement. When the group trained on the small vocabulary was transferred to another small vocabulary after 7 days' training there was a large decrement, while transfer after only one and a half days' training was followed by a smaller decrement for the remaining group. We concluded that subjects had not yet started to generate words in the case of the 100-word vocabulary, but that with the 10-word vocabulary word generating appears at a very early stage.

We are continuing to develop this technique in order to be able to examine the conditions which facilitate or hinder the formation of 'higher habits' in a keyboard skill.

We thank Dr. R. Conrad for ADEHLNORST.

MISCELLANEOUS

Metric to Inch Conversion

The readers of the article by Mrs. Anderton and P. H. Bigg on 'The Yard Unit of Length'[1] may be interested in the results of an investigation following a discussion on metric to inch conversion. The definition of the yard, 0·9144 m exactly, legalized by the Weights and Measures Act, 1963, is equivalent to 1 in. = 25·4 mm exactly. The reciprocal, 1 mm = 1/25·4 in. equals 0·039 370 078 740 157... and we were interested in the way that the first group of figures 3937 was doubled to form the next group 7874 and looked as if it would be doubled again to give 157....

In the case of 1/25·4 it is simple to predict the exact form that the worked out decimal will take. For a reason given later, since 254 is not a multiple of 4, the number will not divide out exactly. If we carry out the long division sum, the remainder after the division taking us as far as 0·03937 is 2. Since we 'started with' 1 it follows that it will continue 007874 when the remainder will be 4 and so on, each cycle of six figures being double the previous six, until we reach a remainder of not 256, of course, but 2. The previous six figures will be 003937 × $2^7 + 1$, which equals 503937, and we see that the number has started to recur a few places before the remainder 2 arrives for the second time. Here is the worked out decimal: it starts to recur after 42 places.

It starts to recur here

0·039 370 078 740 157 480 314 960 629 921 259 842 519 685 ↓ 039

It is interesting to examine the general case of a number of the form $\frac{1}{N}$ where N is an integer. In common with other fractions, it must, if it does not divide out exactly, yield a recurring decimal. If we think of ourselves working out the long division sum and continuing long enough, the remainder must ultimately be repeated after which the number will recur.

When N is an even number the remainder must be an even number and therefore the maximum possible number of stages of division before the number starts to recur is $\frac{N}{2} - 1$. When N is even, but not a multiple of 4, $\frac{1}{N}$ will not divide out exactly. The only number ending in nought which might occur which is exactly divisible by N is $5N$. This can only occur when the remainder from the previous stage of division is $\frac{N}{2}$. However, when N is even but not divisible by 4, $\frac{N}{2}$ will be odd and an odd number cannot occur as a remainder.

The manner in which the cycle of numbers progressively doubles as the decimal value of a reciprocal is worked out is by no means peculiar to 1/25·4. The reciprocal of any rational number, A, can be given by:

$$\frac{1}{A} = \frac{B}{10^K - 2}$$

where K is a positive integer and B is a fraction or an integer.

Expanding by the binomial theorem:

$$\frac{1}{A}=\frac{B}{10^K}\left[1+\frac{2}{10^K}+\frac{2^2}{10^{2K}}+\frac{2^3}{10^{3K}}+\ldots\ldots\right]$$

When calculating $\frac{1}{A}$ in decimals, B must first be expressed as a decimal and it depends on the number of figures in B whether the progressive doubling is immediately apparent or not. In the case of 1/25·4, if we let K equal 6 then $10^K - 2$ equals 999, 998 and $B = 39370$. Thus:

$$\frac{1}{25{\cdot}4}=\frac{39370}{10^6}\left[1+\frac{2}{10^6}+\frac{4}{10^{12}}+\frac{8}{10^{18}}+\ldots\ldots\right]$$
$$= 0{\cdot}03937 + 0{\cdot}000\ 000\ 078\ 74 + \ldots\ldots$$

Dissemination and Storage of Scientific Information in the United Kingdom

The storage and retrieval of scientific information is a subject the study of which has received scant official support in Great Britain; indeed until recently the small volume of research in this field was mostly financed from abroad. Likewise, as stated in the leading article in *Nature* of May 23, Government support for non-conventional means of dissemination and storage of scientific information is very disappointing. The fact that this information is the basic raw material of a research 'industry' with an annual turn-over of several hundred million pounds allows one to sense the seriousness of this lack.

It may be of interest to put on record what has already been done—thanks to the generous help of a number of industrial organizations and a local authority—to build up the nucleus of an organization to provide the information needs of modern research. In late 1962, a number of persons, bringing together experience of academic and industrial research and industrial and governmental administration, formed themselves into a Council and thereby founded the Scientific Documentation Centre, Ltd. This organization was charged *inter alia* with the purposes of compiling central collections of scientific data, of supplying scientific information services and of carrying out research aimed at improving the means of handling scientific information and data.

Substantial progress has already been made with these tasks. Research has shown that papers germane to each of a wide range of subjects are widely scattered throughout the literature—important papers often appearing in the most unexpected journals. As a result of this intelligence, the Centre has built up a series of 'Current Awareness Services' which bring to the individual scientist and to libraries up-to-date notification of papers on subjects of interest to them. This covers more than 1,100 journals, and includes the U.S. Government research reports and a large number of Russian journals. 'Current Awareness Services' are already operating on such subjects as: astronomy; arsenic; carbohydrate chemistry; carbon; carcinogens and carcinostats; cell membranes; ceramics and glass; chromatography; chemical processing; computer applications; cryogenics and superconductors; digitization; electroencephalography; fluorimetry; gas chromatography; geophysics; infra-red of natural phenomena; integrated circuits; interferometers; lasers; management and personnel; marine biology; mass spectroscopy; molluscicides; non-conventional aromatic systems; nuclear magnetic resonance; optical rotary dispersion; packaging; paper technology; pattern recognition; plastics—materials and techniques; polarography and related techniques; polymer analysis; spectrometers (manufacture); spectroscopy (applications); tobacco; terpenes, perfumes and flavours; triazines; town gas; ultra-high pressure; ultra-high vacuum; ultrasonics; water desalination. The Centre has been able to provide material for all 'Current Awareness' requests so far received.

Progress has also been made in the compilation of central collections of scientific data. The Centre's *Spectra Index*, which we regard as a pilot experiment for larger indexes, now contains some 20,000 spectra, the majority not being available in searchable form elsewhere. The *Spectra Index* now comprises the largest generally available collection of spectra or spectral data originating in Europe.

Though the Centre has made substantial progress since its foundation, despite the lack of official financial support, given greater resources, the nucleus that has been set up could very rapidly expand to give more complete and more numerous services to British research.

Early Recognition of Galileo's Work in England

This year, the four hundredth anniversary of the birth of Galileo, has been the occasion of widespread consideration of all aspects of the work of the master, among which the contemporary reception of his work in England is of particular interest to us*. Poets and philosophers, men of general learning and men of science have been cited[1], but among them I have never seen Robert Burton.

Burton's *Anatomy of Melancholy*, which contains many references to Galileo, is a sage and extremely individual consideration of the problems of life, characterized by pertinent quotations from, perhaps, every author accessible at the time. As an example, we may take "every schoolboy hath the famous testament of Grunnius Corocotta Porcellus at his finger ends". Keats, Sterne and Samuel Johnson, men of very different temperament, were, among other celebrities, devoted to the *Anatomy*, the first edition of which was published in 1621.

In his book, Burton, who died just two years before Galileo, refers to Galileo's observation of the Medicean stars and of the ill-resolved ring of Saturn—". . . and that those severall Planets, have their severall Moones about them, as the Earth hath hers, as Galileo hath already evinced by his glasses, foure about *Juppiter*, two about *Saturne* (though *Sittius* the *Florentine* cavill at it)": to his observations on the Moon—". . . hils and dales, and such like concavities, if we may subscribe to, and beleeve Galilies observations": and in the second edition, 1624, to the discovery of the nature of the Milky Way—". . . and that *via lactea*, a confused light of small starres". In later editions he also refers to Galileo's observations of the sun-spots and consideration of the tides. There are also many passing allusions to his work.

The great scholar clearly had an understanding of the significance of Galileo's work and must have been responsible for bringing it to the notice of a great part of the world of learning in Britain.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturer or Lecturer (graduate in fuel science or technology, or in physics or physical chemistry) in the Department of Fuel Science, Houldsworth School of Applied Science—The Registrar, The University, Leeds, 2 (August 10).

Assistant Lecturer (with a degree in economics or agricultural economics, preferably with postgraduate experience in agricultural economics) in Agricultural Economics—The Registrar, The University, Manchester, 13 (August 10).

Lecturer or Assistant Lecturer (graduate in ceramics, glass technology, physics or physical chemistry) in Ceramics—The Registrar, The University, Leeds, 2 (August 10).

Lecturers (2) in Pure Mathematics—The Registrar, The University, Manchester, 13 (August 10).

Lecturer or Assistant Lecturer (with a special interest and qualifications in climatology and/or bio-geography) in Physical Geography—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (August 12).

Lecturer or Assistant Lecturer (with special qualifications in physical chemistry, and preferably some teaching and research experience) in the Department of Chemistry—The Secretary, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (August 14).

Scientific Officer, Grade III or IV (with a first- or second-class honours degree in zoology, physiology, or biochemistry, or a Ph.D. in one of these disciplines) in the Cytochemistry Section, to work with a group on the metabolism of human leucocytes using micro-techniques—The Secretary (B), Imperial Cancer Research Fund, Lincoln's Inn Fields, London, W.C.2 (August 14).

Senior Research Associate or Research Associate (with a good honours degree in physics or an allied subject, and some research experience for appointment in the senior grade) in the Applied Nuclear Science Group in the Department of Physics, for research in the field of neutron radiography—The Administrative Officer, Department of Physics, The University of Birmingham, Birmingham, 15 (August 14).

Assistant Lecturer (preferably interested in problems of embryogenesis and cyto-differentiation) in Zoology—The Registrar, University College of Wales, Aberystwyth (August 15).

College Lecturer (with an honours primary degree in horticulture; a higher degree in a field of work related to horticulture; teaching experience and some practical experience in research, applied or basic) in the Faculty of General Agriculture—Department of Horticulture—The Secretary and Bursar, University College, Dublin, Republic of Ireland (August 15).

Demonstrator (preferably with an interest in parasitology) in Zoology—The Registrar, University College of Wales, Aberystwyth (August 15).

Experimental Officer (with a degree or equivalent qualifications) in the Instrument Laboratory for duties which will include the maintenance and operation of infra-red, ultra-violet and N.M.R. spectrometers and gas chromatographic equipment—Prof. Pauson, University of Strathclyde, George Street, Glasgow, C.1 (August 15).

Head (with a pharmacy or chemistry qualification, experience of pharmacopoeial work and a good knowledge of French) of the Technical Secretariat, European Pharmacopoeia Commission, Strasbourg, for duties covering all aspects of the preparation of the European Pharmacopoeia—The Secretariat, Establishments Division, Council of Europe, Strasbourg, France (August 15).

Lecturer or Assistant Lecturer (preferably with an interest in petrology) in Geology in Queen's College—The Secretary, University of St. Andrews, Queen's College, Dundee (August 15).

Lecturer or Assistant Lecturer (with interests in soil mechanics) in Engineering—The Registrar, The University, Manchester, 13 (August 15).
